(Dated: April 10, 2020)

Topological photonics aims to utilize topological photonic bands and corresponding edge modes to implement robust light manipulation, which can be readily achieved in the linear regime of light-matter interaction. Importantly, unlike solid state physics, the common test bed for new ideas in topological physics, topological photonics provide an ideal platform to study wave mixing and other nonlinear interactions. These are well-known topics in classical nonlinear optics but largely unexplored in the context of topological photonics. Here, we investigate nonlinear interactions of one-way edge-modes in frequency mixing processes in topological photonic crystals. We present a detailed analysis of the band topology of two-dimensional photonic crystals with hexagonal symmetry and demonstrate that nonlinear optical processes, such as second- and third-harmonic generation can be conveniently implemented via one-way edge modes of this setup. Moreover, we demonstrate that more exotic phenomena, such as slow-light enhancement of nonlinear interactions and harmonic generation upon interaction of backward-propagating (left-handed) edge modes can also be realized. Our work opens up new avenues towards topology-protected frequency mixing processes in photonics.

I. INTRODUCTION

One of the most important developments in condensed matter physics in the past decades is the discovery of topological insulating materials. These materials feature gapped bulk but gapless edge modes, which propagate unidirectionally along the system edge and are immune to local disorder, thus opening a promising avenue towards robust wave manipulation protected by topology. Inspired by this development, the emerging field of topological photonics aims to extend these topology related ideas to the realm of photonics, which holds great promises for innovative optical devices by exploiting robust, scattering-free light propagation and manipulation. As the concept of energy band exists at the single particle level both in condensed matter physics and photonics, the goal of realizing photonic topological insulators can be readily achieved in the linear regime of light matter interaction. Indeed, topological phenomena of electromagnetic waves in a linear medium can be understood by mapping Maxwell equations to the Schrödinger equation.

Photonics, however, has several features not present in solid-state physics. For example, optical gain and loss can be utilized to implement non-Hermitian photonics based on parity-time symmetry. The recently realized topological insulator laser demonstrates the power of this new ingredient and could deepen our understanding of the interplay between non-hermiticity and topology in active optical systems. Another well-known feature is the existence of nonlinearity in many optical materials. In fact, optical nonlinear effects play a key role in modern photonic applications, giving rise to a variety of important phenomena, including the formation of solitons, modulation and all-optical switching of optical signals, and frequency conversion for the generation of ultrashort pulses. Thus one expects new physics to emerge when adding nonlinearity to photonic systems with nontrivial topological properties. Indeed, it has been shown that when a photonic topological insulator is embedded in an optical medium with Kerr nonlinearity, lattice edge solitons could arise. The possibility to enhance the conversion efficiency of harmonic generation in the presence of topological edge states has also been studied. Moreover, traveling-wave amplifiers, topological sources of quantum light, nonlinear control and mapping of photonic topological edge states have also been achieved. Despite these important ad-

FIG. 1. (a) Schematic band structure showing the emergent edge modes due to the nontrivial topology of the bulk frequency bands. The edge modes can couple via SHG and THG frequency mixing processes. (b) Real space illustration showing the unidirectional propagation of coupled edge modes along the system edge. The red arrow indicates the excitation source of the fundamental wave whereas the green and blue waves are generated as a result of nonlinear wave mixing.
vances, the feasibility of achieving nonlinear optical mixing of edge states of topological photonic crystals via phase matching, which is one of the most fundamental nonlinear optical processes, has not been explored yet. We would also like to highlight the key differences between our work and previous work\[18,20–24\] on nonlinear optics pertaining to topological edge states: the works\[18,20–24\] are based on one-dimensional (1D) systems, so that the topological edge states are non-propagating optical modes localized at the edges of the 1D system, whereas the system investigated in\[25\] is 2D, i.e., the same as ours, but there is only one topological band gap at the fundamental frequency, and thus there are no nonlinear optical interactions between topological modes.

In this work, we study nonlinear optical interactions of edge modes in topological photonic crystals (PhCs), as per Fig. 1. In particular, we present a detailed study of the band topology of 2D photonic crystals with hexagonal symmetry by mapping out the Chern-number-graded gap phase diagrams. Interestingly, we find that most gaps of the phase diagrams have exactly one edge state in each gap, thus providing a convenient configuration to study the nonlinear interaction of these modes. To this end, by properly tailoring the edge configuration to achieve phase matching, we show that key nonlinear optical processes, such as second- and third-harmonic generation (SHG, THG) can be readily realized in this setup. Beyond this proof-of-principle demonstration of these nonlinear optical processes, we further show that some more exotic nonlinear modes in topological photonic crystals (PhCs), including slow-light enhanced frequency conversion efficiency and higher-harmonic generation upon interaction of so-called backward-propagating (left-handed) modes. All these novel ideas open up new avenues towards active photonic devices with novel functionalities for photonic applications.

The article is organized as follows. In the next section we present and discuss the linear optical properties of the topological photonic crystal, whereas in Sec. [III] we describe the nonlinear optical interaction between one-way topological modes and the coupled-mode theory that governs the nonlinear propagation of interacting topological modes. Moreover, in Sec. [IV] we briefly discuss possible experimental implementations of the ideas presented in this study, whereas in the last section we summarize the main conclusions of this work.

II. LINEAR OPTICAL PROPERTIES OF THE INVESTIGATED TOPOLOGICAL PHOTONIC CRYSTAL

In this section we describe the geometry and material parameters of the topological PhC investigated in this work, as well as the topological properties of the bulk frequency bands and edge topological modes.

A. The system

We begin by describing the system setup. First, 2D PhCs possessing topological frequency gaps around frequencies of $\omega_0$, $\Omega_2 = 2\omega_0$, and $\Omega_3 = 3\omega_0$ are designed in order to study SHG and THG via the corresponding edge modes located inside these gaps. As such, in principle any PhC satisfying this condition could be employed. Nonetheless, it would be beneficial if the first gap is topological since typically, the spectral separation among frequency bands and the gap widths decrease as the frequency increases. In view of this, employing the transverse magnetic (TM) modes of a PhC with hexagonal symmetry lattice, which features Dirac cones at $K$ and $K'$ points of the first Brillouin zone (FBZ) between the first and second band\[25\], is a natural choice. More specifically, one expects that for this configuration the first gap becomes topological when gapping the Dirac cones by breaking the time-reversal symmetry. Consequently, we consider triangular PhCs whose unit cell contains only one cylinder with radius, $r$, as depicted in Fig. 2a. Lattice structures with hexagonal symmetry but having more cylinders in each unit cell, like honeycomb and Kagome lattices with two and three cylinders, respectively, could potentially be employed, too. The second step of our design procedure is to include magnetic and nonlinear materials. To guide potential experimental implementations and for the sake of specificity, we consider cylinders with low-permittivity ($\varepsilon_1$), non-magnetic nonlinear material immersed in a magnetic background material with high-permittivity ($\varepsilon_2$). Note that the permittivity of the cylinders has to be lower than that of the background to ensure that Dirac cones exist.

B. Topological properties of the bulk frequency bands

We now move on to the topological properties of the bulk frequency bands of the proposed non-magnetic ($\mu = \mu_0$) PhCs whose unit cell and FBZ are shown in Figs. 2a and 2b. In the following, we use normalized frequency and momentum, $\tilde{\omega} = \omega a / 2\pi c$ and $\tilde{k} = k a / \pi$, respectively, where $c$ is the speed of light and $a$ is the lattice constant. Figure 2c shows the photonic band structure of the PhC with $r = 0.4 a$, $\varepsilon_1 = 3$, and $\varepsilon_2 = 18$ from which one can see the Dirac cone between the first and second bands at $K$ and $K'$ points. All band structures presented in this work were calculated using COMSOL Multiphysics 5.3\[25\], a commercial software package based on the finite-element method, and validated using Synopsis’s Band-SOLVE software\[26\].

As known, the Chern number of each band is zero in systems with time-reversal symmetry\[25\]. A common way to break time-reversal symmetry and generate bands with nonzero Chern number is to use magnetic material\[25,31\], where the permeability tensor of the material under an external magnetic field along the $z$-axis possesses off-diagonal components in the $x$–$y$ plane, i.e.,

$$
\mu = \begin{pmatrix}
\mu_0 & i\mu_i \\
-i\mu_i & \mu_0
\end{pmatrix}.
$$

Here, we set $\mu_0 = 1$ and take $\mu_i$ as a parameter to quantify the effect of time-reversal symmetry breaking. Figure 2d shows...
the photonic band structure for $\mu_i = 0.8$, where one can see that the Dirac cone is now gapped.

To characterize the topology of the frequency bands, we calculate the Chern number of the $n$th band, defined as

$$C_n = \frac{1}{2\pi} \oint_{FBZ} \mathcal{A}_n(\mathbf{k}) \cdot d\mathbf{k},$$

(2)

where $\mathcal{A}_n(\mathbf{k}) = \langle \mathbf{E}_n(\mathbf{k})| / |\mathbf{E}_n(\mathbf{k})\rangle$ and $\mathcal{F}_n(\mathbf{k}) = \nabla_k \times \mathcal{A}_n(\mathbf{k})$ are the Berry connection and Berry curvature, respectively, with $\mathbf{E}_n(\mathbf{k})$ being the electric field of the $n$th band mode with momentum, $\mathbf{k}$. The momentum-space integral is performed over the FBZ, whereas the inner product of the Berry connection is defined as $\langle \mathbf{E}_n| \mathbf{E}_m \rangle = \int e(\mathbf{r}) \mathbf{E}_n(\mathbf{r}) \cdot \mathbf{E}_m(\mathbf{r}) d\mathbf{r}$, with the real-space integral performed over the unit cell. The Chern number is calculated using the algorithm described in (for more details about this algorithm, see Appendix A).

The calculated Chern numbers of the photonic bands are indicated in Fig. 2 on top of each band, and the gap Chern number, defined as the sum of the Chern numbers of the bands below the gap, is also given for each gap. The gap Chern number characterizes the topology of the gap in the sense that its sign determines the propagation direction of the edge modes and its value indicates the number of edge states located inside the gap. An interesting feature revealed by Fig. 2 is that the first few gaps have Chern number $C = 1$, which means that there is one edge mode in each gap and all propagate in the same direction. Therefore, this configuration provides a convenient platform to study nonlinear optical processes, e.g., SHG and THG.

To understand intuitively what regimes can be achieved with this setup, it is instructive to map out the Chern-number-graded gap phase diagrams, defined as the variation of the gap Chern numbers with the system parameters $r$, $\epsilon_1$, $\epsilon_2$, and $\mu_i$. We show these gap phase diagrams in Fig. 2 for $r = 0.4a$, $\epsilon_1 = 3$, $\epsilon_2 = 18$, and $\mu_i = 0.8$, when one parameter is varied while keeping fixed the others. The results show that most domains of the phase diagrams have $C = 1$. Moreover, one can also see gaps with $C = 2$, $C = 3$ and, importantly, even gaps with negative Chern numbers, $C = -1$ and $C = -2$. As we will demonstrate, this variety of values of the gap Chern numbers leads to particularly rich physics when nonlinear interactions of topological modes are considered.

C. Topological properties of the edge modes

Guided by the phase diagrams in Fig. 2, we choose the suitable parameters to create photonic gaps suitable to study SHG and THG. According to the principle of bulk-edge correspondence in systems with finite size, when the gap has nonzero Chern number, one-way edge modes will emerge in the gap. We present in Fig. 3 the photonic band structure...
of a PhC strip with 30 unit cells along the $y$-axis and periodic along the $x$-axis. This figure illustrates the emergence of various edge states across bulk photonic gaps in a range of frequencies. For the sake of clarity, we mark in red and blue the edge states formed on the top and bottom edges of the PhC strip, respectively. The field profiles of the edge states at frequencies $\bar{\omega} = 0.2$, $\bar{\Omega}_2 = 2\bar{\omega} = 0.4$, and $\bar{\Omega}_3 = 3\bar{\omega} = 0.6$, presented in Fig. 3b, highlight the key feature of the edge state – exponential decay of the field away from the edge.

A well-known prerequisite for achieving efficient frequency conversion processes is to phase match the interacting waves\textsuperscript{[15]}. In the current context, this requires a method to tune the wave vectors of the edge modes. As far as we know this issue has not been previously discussed, perhaps due to the irrelevance of phase matching in other (linear) physics involving edge modes. We find that the wave vector of edge modes can be readily tuned by simply changing the configuration of the edge termination. Figure 3c shows how the edge-mode band of the top edge changes when varying the location of the edge termination (see the sketch at the top of Fig. 3c). In general, we find that the edge-mode band shifts by about one reciprocal lattice vector, $G = 2\pi/a$, as one increases the width of the PhC strip by one unit cell. Note that due to the periodicity of the system along the $x$-axis, one can always shift the wave vector of the edge mode to the region of $[-\pi/a, \pi/a]$ by adding a momentum of $nG$, with $n$ a suitable integer.

FIG. 3. (a) Photonic band structure of a 1D PhC strip that is periodic along the $x$-axis and has finite size of 30 unit cells along the $y$-axis (top and bottom edges are terminated by a perfect electric conductor at $r = 0.42a$). The other simulation parameters are $e_1 = 3$, $e_2 = 20$, and $\mu_1 = 0.8$. The edge modes in the three gaps around $\bar{\omega} = 0.2$, $0.4$, and $0.6$ are depicted by red and blue lines and are formed at the top and bottom edges of the PhC, respectively. (b) Field profiles of the three one-way edge modes at $\bar{\omega} = 0.2$, $0.4$, and $0.6$ of the top edge. Exponential decay of the field around the PhC edge can be observed (integers indicate the number of unit cells). (c) Dispersion curves of edge modes can be tailored by changing the edge termination, as indicated in the sketch.

### III. NONLINEAR OPTICAL INTERACTION BETWEEN ONE-WAY TOPOLOGICAL MODES

In this section we first introduce the coupled-mode theory (CMT) for SHG mediated by the topological edge modes (a similar derivation for THG is given in the Appendix\textsuperscript{[3]}). We then present proof-of-concept results, both numerical and analytical, on topics, such as SHG and THG upon edge-mode interaction, SHG in the slow-light regime, and SHG via interaction between forward- and backward-propagating edge modes.

#### A. Coupled-mode theory describing second-harmonic generation

The derivation of the CMT for SHG upon nonlinear interaction of topological edge-modes follows the formulation of the CMT governing nonlinear pulse interactions in nonlinear PhC slab waveguides\textsuperscript{[33,34]}. Thus, to begin with, we note that our system contains magneto-optic materials, i.e., $\hat{\mu} \neq \hat{\mu}^\dagger$, but rather $\hat{\mu} = \hat{\mu}^\dagger$, so that we will use the conjugated form of the Lorentz reciprocity theorem\textsuperscript{[17]} for the vector field $\vec{F} = \vec{E}^f \times \vec{H}_2^e + \vec{E}_2^e \times \vec{H}^f$, where $\{\vec{E}_1, \vec{H}_1\}$ are the electric and magnetic fields of an eigenmode of the topological PhC, whereas $\{\vec{E}_2, \vec{H}_2\}$ are the electric and magnetic fields under the effect of nonlinear polarization $\vec{P}_{NL}$. Here, $\hat{\mu}$ is the magnetic permeability tensor and the symbols "$T$" and "$\dagger$" indicate the transpose and Hermitian transpose operations, respectively. Note also that as we consider 2D PhCs, we denote by $\hat{z}$ the out-of-plane direction and all the physical quantities only depend on the $x$ and $y$ coordinates.

To start with, we write the eigenmodes of the topological PhC, both at the fundamental ($f$) and second-harmonic ($s$) frequencies, denoted by $\omega_0$ and $\Omega_2 = 2\omega_0$, respectively, in their Bloch forms, i.e.,

$$E_1^f(r, \omega_0) = \frac{e_f(r, \omega_0)}{\sqrt{P_0}} e^{i(k_{z0}x)}.$$  

\hspace{1cm} (3a)
\[ \mathbf{H}_f^f(r, \omega_0) = \frac{\mathbf{h}_f(r, \omega_0)}{\sqrt{P_f}} e^{j k_f(\omega_0)x}, \quad (3b) \]

and

\[ \mathbf{E}_f^f(r, \Omega_2) = \frac{\mathbf{e}_f(r, \Omega_2)}{\sqrt{P_e}} e^{j k_e(\Omega_2)x}, \quad (4a) \]

\[ \mathbf{H}_f^s(r, \Omega_2) = \frac{\mathbf{h}_f(r, \Omega_2)}{\sqrt{P_s}} e^{j k_s(\Omega_2)x}. \quad (4b) \]

In these equations, \( \{\mathbf{e}_f, \mathbf{h}_f\} \) and \( \{\mathbf{e}_s, \mathbf{h}_s\} \) are the lattice-periodic electric and magnetic Bloch fields of the fundamental and second-harmonic waves, respectively, \( k_{f,s} \) are the corresponding Bloch wavevectors, assuming that the waves propagate along the \( x \)-axis, and the vector \( r \) lies in the transverse \((x, y)\)-plane. If we choose the normalization constants \( P_{f,s} \) such that

\[
\frac{1}{4} \int_{-\infty}^{\infty} (\mathbf{e}_{f,s}^* \times \mathbf{h}_{f,s} + \mathbf{e}_{f,s} \times \mathbf{h}_{f,s}^*) \cdot \mathbf{\hat{s}} \, dy = P_{f,s}, \quad (5)
\]

the modes \( \{\mathbf{E}_f^f, \mathbf{H}_f^f\} \) and \( \{\mathbf{E}_f^s, \mathbf{H}_f^s\} \) in Eqs. (3) and (4), respectively, carry 1 W per unit length along the longitudinal \( z \)-axis.

The mode power is related to the mode energy per unit length contained in one unit cell, \( W \), and the group velocity, \( v_g \), via the relation:

\[
P_{f,s} = \frac{W_{f,s}}{a} = \frac{W_{\text{el}} + W_{\text{mag}}}{a} v_g, \quad (6)
\]

where, for non-dispersive media, the electric and magnetic energies are given by the following formulæ:

\[
W_{\text{el}} = \frac{1}{4} \int_{A_{\text{eff}}} \mathbf{E}_{f,s} \cdot \mathbf{E}_{f,s} \, dA, \quad (7a)
\]

\[
W_{\text{mag}} = \frac{1}{4} \int_{A_{\text{eff}}} \mathbf{H}_{f,s} \cdot \mathbf{H}_{f,s} \, dA. \quad (7b)
\]

One can also define an effective width of the mode, \( w_{\text{eff}} \), in terms of the Poynting vector of the field\([9]\):

\[
w_{f,s}^{\text{eff}} = \left( \int_{-\infty}^{\infty} \mathbf{E}_{f,s} \times \mathbf{H}_{f,s} \, dy \right)^2 \int_{-\infty}^{\infty} |\mathbf{E}_{f,s}|^2 \, dy. \quad (8)
\]

From the Maxwell equations, one can readily infer that, in the frequency domain, the optical modes satisfy the following equations:

\[
\nabla \times \mathbf{E}_1 = i \omega \varepsilon \mathbf{H}_1, \quad (9)
\]

\[
\nabla \times \mathbf{H}_1 = -i \omega \varepsilon \mathbf{E}_1, \quad (10)
\]

where \( \omega = \omega_0 \) and \( \omega = \Omega_2 \) for the fundamental and second-harmonic waves, respectively.

Following the CMT, for the perturbed problem, we write the electric and magnetic fields of the fundamental and second-harmonic waves as:

\[
\mathbf{E}_f^f(r, \omega_0) = A_f(x) \frac{\mathbf{e}_f(r, \omega_0)}{\sqrt{P_f}} e^{j k_f(\omega_0)x}, \quad (11a)
\]

\[
\mathbf{H}_f^f(r, \omega_0) = A_f(x) \frac{\mathbf{h}_f(r, \omega_0)}{\sqrt{P_f}} e^{j k_f(\omega_0)x}, \quad (11b)
\]

where \( A_f(x) \) and \( A_s(x) \) are the slowly-varying envelopes of the fundamental and second-harmonic waves, respectively, under the effect of the nonlinear polarization \( P_{NL} \). The power per unit length carried by the fundamental and second-harmonic fields are \( |A_f(x)|^2 \) and \( |A_s(x)|^2 \), respectively, meaning that these field amplitudes are measured in \( \sqrt{W/m} \).

The Maxwell equations for the perturbed fields are:

\[
\nabla \times \mathbf{E}_2 = i \omega_0 \varepsilon \mathbf{H}_2, \quad (13)
\]

\[
\nabla \times \mathbf{H}_2 = -i \omega_0 \varepsilon \mathbf{E}_2 - i \omega_0 P_{NL}^N, \quad (14)
\]

where \( \omega = \omega_0 \) and \( \omega = \Omega_2 \) for the fundamental and second-harmonic waves, respectively. Moreover, starting from the equation for the second-order nonlinear polarization in the time domain, \( P_{NL}^N (r,t) = \chi^{(2)} (r,t) : \mathbf{E} (r,t) \mathbf{E}^* (r,t) \), where \( \chi^{(2)} \) is the second-order susceptibility tensor, one can easily show that the nonlinear polarization at the fundamental and second-harmonic frequencies can be written as:

\[
P_{NL}^f (r, \omega_0) = \frac{2 A_f^2 (x)}{P_f} \chi^{(2)} : \mathbf{e}_f (r, \omega_0) \mathbf{e}_f (r, \Omega_2) e^{j (k_f - k_s)x}, \quad (15a)
\]

\[
P_{NL}^s (r, \Omega_2) = \frac{A_s^2 (x)}{P_s} \chi^{(2)} : \mathbf{e}_s (r, \omega_0) \mathbf{e}_s (r, \omega_0) e^{2 j k_s x}. \quad (15b)
\]

We now use the 2D form of the divergence theorem, which states that for any general function \( F \),

\[
\int_A \nabla \cdot \mathbf{F} \, dA = \frac{\partial}{\partial x} \int_A \mathbf{F} \cdot \mathbf{x} \, dA + \oint_{\partial A} \mathbf{F} \cdot \mathbf{n} \, dl, \quad (16)
\]

where \( A \) is an arbitrary cross-section perpendicular to the direction of wave propagation, \( \mathbf{x} \), and \( \mathbf{n} \) is the unit vector outwardly normal onto \( \partial A \) in the plane of \( A \). If we take \( A \) to extend to infinity along the \( y \)-axis, the line integral vanishes for fields that decay exponentially to infinity. Moreover, the l.h.s. of Eq. (16) can be written as:

\[
\int_{-\infty}^{\infty} \nabla \cdot \mathbf{F} \, dy = i \omega \int_{-\infty}^{\infty} \mathbf{E}^*_f \cdot P_{NL}^f dy. \quad (17)
\]

In deriving this equation, we used the vector identity \( \nabla \cdot (A \times B) = B \cdot (\nabla \times A) - A \cdot (\nabla \times B) \) and the fact that, since \( \hat{e} \) and \( \hat{\mu} \) are Hermitian, the identities \( \mathbf{E}_{f,s}^* = \hat{e} \mathbf{E}_{f,s} = (\hat{e} \mathbf{E}_{f,s})^* \cdot \mathbf{E}_{f,s} \) and \( \mathbf{H}_{f,s}^* \cdot \mathbf{H}_{f,s} = (\hat{\mu} \mathbf{H}_{f,s})^* \cdot \mathbf{H}_{f,s} \) hold.

Let us now consider Eq. (17), written for the fundamental frequency:

\[
\int_{-\infty}^{\infty} \nabla \cdot \mathbf{F} \, dy = \frac{2 i \omega_0 A_f^2}{P_f \sqrt{P_s}} \int_{-\infty}^{\infty} \mathbf{e}_f \cdot \chi^{(2)} (\omega_0 - \omega_0, \Omega_2) : \mathbf{e}_f \, dy, \quad (18)
\]
where $\Delta k = k_s(\Omega_2) - 2k_f(\omega_0)$ is the wavevector mismatch. Moreover, the r.h.s. of Eq. (16) can be cast as:

$$\frac{\partial}{\partial x} \int_{-\infty}^{\infty} F \cdot \mathbf{\hat{x}} dy = \frac{\partial}{\partial x} \int_{-\infty}^{\infty} \left( E_1^{(s)} \times H_2^f + E_2^{(s)} \times H_1^f \right) \cdot \mathbf{\hat{x}} dy = dA_f(x) \frac{1}{P_f} \int_{-\infty}^{\infty} \left( e_f^* \times h_f + e_f \times h_f^* \right) \cdot \mathbf{\hat{x}} dy = 4 \frac{dA_f(x)}{dx} \frac{dA_f(x)}{dx}. \quad (19)$$

Comparing Eqs. (18) and (19), we arrive at the equation describing the slowly-varying mode amplitude $A_f(x)$:

$$\frac{dA_f(x)}{dx} = i\gamma_f^{(2)}(x)A_f^*(x)A_f(x)e^{i\Delta k x}, \quad (20)$$

where the nonlinear coefficient at the fundamental frequency is

$$\gamma_f^{(2)}(x) = \frac{\omega_0}{2P_f \sqrt{\mu_f}} \int_{-\infty}^{\infty} e_f^* \cdot \chi_f^{(2)}(\omega_0; -\omega_0, \Omega_2) : e_f e_f dy. \quad (21)$$

The equation governing the evolution of the slowly-varying mode amplitude of the second-harmonic, $A_s(x)$, is derived in a similar way. Thus, when $\omega = \Omega_2$, the l.h.s. of Eq. (16) becomes:

$$\int_{-\infty}^{\infty} \nabla \cdot F dy = \frac{i\Omega_2 A_f^* e^{-i\Delta k x}}{P_f \sqrt{\mu_f}} \int_{-\infty}^{\infty} e_f^* \cdot \chi_f^{(2)}(\Omega_2; \omega_f, \omega_0) : e_f e_f dy, \quad (22)$$

and the r.h.s. of Eq. (16) can be expressed as:

$$\frac{\partial}{\partial x} \int_{-\infty}^{\infty} F \cdot \mathbf{\hat{x}} dy = \frac{\partial}{\partial x} \int_{-\infty}^{\infty} \left( E_1^{(s)} \times H_2^s + E_2^{(s)} \times H_1^s \right) \cdot \mathbf{\hat{x}} dy = \frac{dA_s(x)}{dx} \frac{1}{P_f} \int_{-\infty}^{\infty} \left( e_s^* \times h_s + e_s \times h_s^* \right) \cdot \mathbf{\hat{x}} dy = 4 \frac{dA_s(x)}{dx} \frac{dA_s(x)}{dx}. \quad (23)$$

Finally, from Eqs. (22) and (23), we obtain the governing equation for the slowly-varying amplitude $A_s(x)$:

$$\frac{dA_s(x)}{dx} = i\gamma_s^{(2)}(x)A_s^*(x)A_s(x)e^{-i\Delta k x}, \quad (24)$$

where the nonlinear coefficient at the second-harmonic is

$$\gamma_s^{(2)}(x) = \frac{\Omega_2}{4P_f \sqrt{\mu_f}} \int_{-\infty}^{\infty} e_s^* \cdot \chi_s^{(2)}(\Omega_2; \omega_f, \omega_0) : e_s e_s dy. \quad (25)$$

In order to better understand the effects of the slow light on the strength of the nonlinear interaction, we use Eq. (6) in conjunction with Eq. (7) to express the nonlinear coefficients as follows:

$$\gamma_f^{(2)}(x) = \frac{4Z_0^{3/2} \omega_0 n_{g,f} \sqrt{n_{g,s}}}{\sqrt{\mu_f}} \chi_{eff,f}^{(2)}(x) = \frac{4\omega_0}{\sqrt{\mu_0} \sqrt{v_{g,f} \sqrt{n_{g,s}}}} \chi_{eff,f}^{(2)}(x), \quad (26a)$$

$$\gamma_s^{(2)}(x) = \frac{2Z_0^{3/2} \Omega_2 n_{g,f} \sqrt{n_{g,s}}}{\sqrt{\mu_f}} \chi_{eff,s}^{(2)}(x) = \frac{2\Omega_2}{\sqrt{\mu_0} \sqrt{v_{g,f} \sqrt{n_{g,s}}}} \chi_{eff,s}^{(2)}(x), \quad (26b)$$

where $Z_0$ is the vacuum impedance, $n_{g,f,s} = c/v_{g,f,s}$ are the group indices of the two interacting modes, and the effective second-order susceptibilities $\chi_{eff,f,s}^{(2)}(x)$ are defined by the following relations:

$$\chi_{eff,f}^{(2)}(x) = a^2 \int_{-\infty}^{\infty} e_f^* \cdot \chi_f^{(2)}(\omega_0; -\omega_0, \Omega_2) : e_f e_f dy \int_{A_{cell}} (e_f^* \cdot e_f + Z_0^2 h_f^* \cdot h_f) / dA \int_{A_{cell}} (e_f^* \cdot e_f + Z_0^2 h_f^* \cdot h_f) / dA \left[ a^2 \int_{-\infty}^{\infty} e_f^* \cdot \chi_f^{(2)}(\Omega_2; \omega_f, \omega_0) : e_f e_f dy \int_{A_{cell}} (e_f^* \cdot e_f + Z_0^2 h_f^* \cdot h_f) / dA \int_{A_{cell}} (e_f^* \cdot e_f + Z_0^2 h_f^* \cdot h_f) / dA \right]^{1/2}. \quad (27a)$$

It should be noted that the nonlinear coefficients and nonlinear effective susceptibilities vary with the x-coordinate over a characteristic length equal to the lattice constant, $a$, whereas the characteristic length over which the field amplitudes vary is equal to $1/\Delta k$. When the two interacting waves are nearly phase-matched, $a \ll 1/\Delta k$. Therefore, in order to describe the nonlinear mode interactions, it is convenient to introduce the averaged physical quantities

$$\overline{\gamma}_f^{(2)} = \frac{1}{a} \int_{-\infty}^{\infty} \gamma_f^{(2)}(x) dx, \quad (28a)$$

$$\overline{\chi}_{eff,f}^{(2)} = \frac{1}{a} \int_{-\infty}^{\infty} \chi_{eff,f}^{(2)}(x) dx, \quad (28b)$$

where $a$ is the lattice constant.
where \( \chi_0 \) is arbitrary. Then, by averaging Eqs. (20) and (24), we arrive at the system of CMT governing the nonlinear dynamics of the interacting modes:

\[
\frac{d\bar{A}_f(x)}{dx} = i\gamma_f^{(2)} \bar{A}_f(x)\bar{A}_r(x)e^{i\Delta k x}, \tag{29a}
\]

\[
\frac{d\bar{A}_r(x)}{dx} = i\gamma_r^{(2)} \bar{A}_r(x)e^{-i\Delta k x}, \tag{29b}
\]

where \( \bar{A}_f(x) \) and \( \bar{A}_r(x) \) are the averaged mode amplitudes at the fundamental and second-harmonic frequencies, respectively.

### B. Description of the full-wave numerical simulations approach

The full-wave dynamics of the nonlinear interaction of topological edge-modes (SHG and THG) were determined numerically using the module “Electromagnetic Waves, Frequency Domain” of COMSOL Multiphysics. Thus, to simulate the nonlinear frequency mixing processes in COMSOL, we defined two “Electromagnetic Waves, Frequency Domain” models, one for the fundamental frequency \( \omega_0 \) and one for the second (third) harmonic frequency \( \Omega_2 \) (\( \Omega_3 \)). The two models are coupled using a “Polarization” feature added to each of the models. We assumed that for both the SHG and THG cases the nonlinear susceptibilities are diagonal tensors, the diagonal elements being \( \chi_2 \) and \( \chi_3 \), respectively.

For the study of the SHG (where we consider TM-polarized modes), the nonlinear polarizations at the FF and SH are:

\[
P_{NL,z}^{(\mu)} = 2\chi_2 E_2^* E_1^r, \tag{30a}
\]

\[
P_{NL,z}^{(\Omega_2)} = \chi_2 E_2^2. \tag{30b}
\]

For the study of THG, the corresponding nonlinear polarizations are:

\[
P_{NL,z}^{(\mu)} = 3\chi_3 E_3^* E_1^r E_2^2, \tag{31a}
\]

\[
P_{NL,z}^{(\Omega_3)} = \chi_3 E_3^2. \tag{31b}
\]

### C. Second-harmonic generation and third-harmonic generation upon edge-mode interaction

We now investigate nonlinear frequency conversion processes \( \text{via} \) the edge modes indicated in Fig. 3 by using full-wave numerical simulations of Maxwell equations (for simulation details, see Appendix \( \text{A} \)), with the results being summarized in Fig. 4. In the following, we mainly focus on the discussion of SHG, as the results of THG can be understood similarly.

We consider cylinders made of homogeneous and isotropic nonlinear material with a scalar nonlinear second-order susceptibility of \( \chi_2^{(2)} = 10^{-21} \text{ C V}^{-2} \) (typical value of \( \chi_2^{(2)} \) varies from \( 10^{-24} \text{ C V}^{-2} \) to \( 10^{-21} \text{ C V}^{-2} \)). The pump electric field \( E_1 \) is induced by an external source whereas \( E_2 \) by the nonlinear polarization at the SH, generated by \( E_1 \). The amplitude of \( E_1 \) is chosen such that the undepleted pump approximation holds, \( \text{i.e.} \) the amplitude of \( E_1 \) is much larger than that of \( E_2 \) and thus \( E_1 \) is roughly constant during the frequency conversion process. Note, however, that our analysis remains valid when this condition is not fulfilled, too, our choice being chiefly guided by a more facile comparison between numerical and theoretical results, which is possible in this propagation regime.

From Figs. 3 and 4, one can observe that the field profiles of \( E_1 \) and \( E_2 \) are indeed the same as the profiles of the edge modes shown in Fig. 3, indicating that the two edge modes are indeed nonlinearly interacting \( \text{via} \) the SHG — a key result of our work. The physics of this nonlinear process can be accurately captured by the CMT (see Appendix \( \text{C} \)). In particular, the period of spatial oscillations of the SH field \( E_2 \) is determined by the wave-vector mismatch \( \Delta k = k_{SH} - 2k_{FF} \) (\( \Delta k = k_{TH} - 3k_{FF} \) for THG). As a result, we can straightforwardly compare the numerically extracted oscillation period of \( E_2 \) with the theoretical prediction of \( \Lambda_2 = 2\pi/\Delta k \), thus confirming that the key physics of nonlinear frequency conversion processes is validated by our simulations.

We further validate these conclusions using a much larger simulation domain, with the corresponding results being presented in Figs. 4-6. In Fig. 4, where \( \omega_0 = 0.2, \Omega_2 = 0.4, \) and \( \Delta k = 0.054 \), we have \( \Lambda_2 = 37 \). The agreement between the predictions the CMT and direct numerical simulations, of both the period and amplitude of SH power oscillation along the propagation distance, is excellent. We calculate \( \Delta k \) for all the frequencies of the interacting edge modes from Fig. 4 and present the theoretically calculated and numerically extracted oscillation period \( \Lambda_2 \) in Fig. 4a. An excellent agreement between the two results can be observed, which confirms the key physics of SHG, namely phase matching is indeed at work in our photonic system and SHG purely \( \text{via} \) nonlinear interaction of edge modes occurs in our setup. We also confirm the edge mode mediated THG as shown in Figs. 4g-4i, where the discrepancy in Fig. 4f between the numerical and theoretical results is due to inherent limitations of numerical simulations at very small \( \Delta k \).

While the SHG and THG of one-way edge modes are governed by the usual mechanism of topological protection from the chiral nature of the edge modes, where the modes can bypass structural defects, such as the sharp bends shown in Figs. 4-c, without undergoing backscattering, the effect of structural defects on the coherence properties of nonlinear processes is an important but less understood problem. In order to answer this key question, and taking SHG as an example, we introduce a structural defect at a certain location along the edge where the fundamental and second-harmonic modes co-propagate and present the corresponding simulation results in Fig. 4. Thus, it can be seen that, as expected, both the fundamental and second-harmonic modes bypass the defect without experiencing backscattering. More importantly, by comparing the results in Figs. 4 and 4, one can infer that the coherence length of the SHG, namely the oscillation period of the amplitude of the interacting modes, is not altered by the interaction with the structural defect. In other words, the coherence of the nonlinear interaction is preserved.
in the presence of defects, meaning that the phase-matched nature of the nonlinear mode interaction process is immediately regenerated after the mode interaction with each defect. As the coherence length crucially determines the conversion efficiency of the nonlinear processes, topological protection of the coherence length in nonlinear frequency mixing processes demonstrates a new area where topology can boost the performance of photonic devices based on nonlinear optical processes.

Another relevant question, which we do not intend to fully answer here, is how other types of perturbations affect the phase-matching condition of the nonlinear optical interaction of topological modes. From a practical point of view, the most relevant such perturbation is structural disorder, and in this context we consider two cases, namely weak and strong disorder. The case of weak disorder can be analyzed using perturbative methods. Thus, let us assume that in the absence of disorder the frequency-dependent wave-vector mismatch, \( \Delta k(\omega) \), vanishes at a certain frequency \( \omega_0 \), that is \( \Delta k(\omega_0) = 0 \). Then, adding weak disorder to the unperturbed system will change the modal dispersion of the interacting modes, such that the wave-vector mismatch varies, say, by a small quantity \( \delta k(\omega) \). Furthermore, since one expects that \( \delta k(\omega) \) has constant sign around the frequency \( \omega_0 \), it can be seen that there is a frequency \( \omega_0 + \delta \omega = \omega_0 + \delta k(\omega) \) at which the wave-vector mismatch in the presence of disorder, \( \Delta k_f(\omega) = \Delta k_f(\omega_0) + \delta k(\omega) \), vanishes, that is \( \Delta k_f(\omega_0 + \delta \omega) = 0 \). To validate this argument, one would have to employ full-wave simulations of the nonlinear optical interaction of topological modes and average the results over an ensemble of disorder realizations large enough to ensure statistical convergence.
FIG. 5. (a) Dispersion of edge modes at $\omega_0$ and $\Omega_2$ determined for $t = 0.24\mu$, as in Fig. 3c, whereas the other simulation parameters are the same as those in Fig. 2. The dispersion curve of the FF mode now shows a plateau leading to a peak of $n_g$ at $0 = 0.1968$. The frequency of the phase-matching point $\bar{\omega}_g = \bar{\omega} \Delta \bar{k} = 0$ is $\bar{\omega}_g = 0.1972$. (c) The enhancement of the SH conversion efficiency due to the slow-light effect. The left panel shows an example where the SH power $P_2$ at two different frequencies, $\bar{\omega}_1 = 0.1960$ and $\bar{\omega}_2 = 0.1975$, shows the same oscillation period, yet its oscillation amplitude at $\bar{\omega}_2$ (closer to the maximum of $n_g$, located at $\bar{\omega}_2$) is enhanced compared to that at $\bar{\omega}_1$. The right panels show schematically the formal definition of the enhancement factor $\eta$ (top) and its frequency dependence in the slow-light regime (bottom).

To achieve convergence of the ensemble average, this computational analysis would be rather unfeasible as just a single full-wave simulation requires several days to complete. On the other hand, for large values of disorder strength, concepts such as optical modes, topological properties, and photonic band gaps cease to exist, and therefore we do not investigate this case any further.

D. Second-harmonic generation in the slow-light regime

The slow-light regime, characterized by a significantly reduced group velocity, $v_g = d\omega / dk$, can be particularly effective in enhancing the efficiency of nonlinear wave interactions. In the context of SHG, this can be achieved when $v_g$ is reduced at one or both interacting waves. As Fig. 3c suggests, when one varies the location of the edge termination, the shift of the dispersion curve of the edge modes is accompanied by a change of its shape. For example, we find that for $t = 0.24\mu$, the dispersion curve of the edge mode at the FF has a plateau (see Fig. 3h) leading to a peak of the group index, $n_g = c / v_g$, at $\bar{\omega}_g$ (see Fig. 5h), where we define the slow-light regime by the condition $n_g > 2$ [19]. On the other hand, the fact that the phase-matching spectral point $\bar{\omega}_g = \bar{\omega} \Delta \bar{k} = 0$ provides a valuable approach to study the interplay between slow-light and phase-matching effects in the enhancement of SH conversion efficiency.

E. Second-harmonic generation via interaction between forward- and backward-propagating edge modes

We now move on to an important class of nonlinear processes, which are challenging to achieve in regular optical media, and demonstrate SHG via interaction of backward-propagating edge modes. To this end, we exploit the existence of photonic gaps with negative Chern number in our system, as per Fig. 2. In particular, we explore a case where the gap at the FF has $C = 1$, while the gap at the SH has $C = -1$. The corresponding edge modes are shown in Fig. 4, which illustrates the signature of modes with negative Chern number, i.e., the slope of the mode dispersion curve (at $\Omega_2$) is negative. The simulation results of the field profiles are presented in Figs. 6a and 6b. It clearly shows that whereas the mode at the FF prop-

FIG. 6. SHG via interaction between forward- and backward-propagating edge modes. This setting exploits the existence of a gap with negative Chern number at the SH for $\tau = 0.41\mu, \epsilon_1 = 3, \epsilon_2 = 20, \mu = 0.82$ (see Fig. 5b) and edge termination at $t = 0.82\mu$ (see Fig. 3e). (a-b) Field intensity profiles of $E_1$ and $E_2$ calculated for $2\bar{\omega}_0 = 0.74$, illustrating that whereas the mode at the FF propagates clockwise (C = 1 for the $\omega_0$ gap), the edge mode at the SH is backward-propagating (C = -1 for the $\Omega_2$ gap). In the simulation, ABC is used for the bottom edge while PEC boundaries for the other edges. (c) Edge states of the two gaps, which show the hallmark of edge modes with negative Chern number: the slope of the dispersion curve of the edge mode at the SH is negative. (d) Comparison between the theoretically calculated and the numerically extracted oscillation period $\Lambda$, confirming that the phase matching mechanism is involved in this unusual nonlinear interaction regime.
agates clockwise, as it is a forward-propagating mode, the SH wave propagates counterclockwise because in the left-half region of the simulation domain there is no field at the FF and consequently no nonlinear polarization at the SH (note that we placed the source of the FF wave at the middle of the top edge and used absorbing boundary condition for the bottom edge). We also confirm that the phase matching mechanism is involved in this unusual mode interaction regime, as per the results in Fig. 6. This backward-propagating mode regime is promising for practical applications where one requires to separate the FF mode from the mode generated at the SH.

IV. EXPERIMENTAL CONSIDERATIONS

The key idea of this work involves coupling the edge states within different topological frequency band gaps via optical nonlinearity. This central idea of our study is rather general and can potentially be implemented in different experimental platforms available for topological photonics. In this section, for the sake of completeness, we first present a set of materials and parameters that can be used to experimentally implement our model system. Then we discuss further possible experimental platforms that can be used to implement the theoretic ideas and results presented in our work.

Since we separate the magnetic and nonlinear material components as the background and cylindrical regions of the PhC, respectively, possible experimental implementations could be readily conceived considering the fact that at microwave frequencies, magnetic materials to realize topological band gaps and nonlinear materials to realize frequency mixing are routinely used. For example, to demonstrate the topology-protected SHG, one can use as the background medium yttrium iron garnet (YIG), a magnetic material widely used in recent experiments in topological photonics. This material has relative permittivity $\epsilon = 15$ and saturation magnetization of $4\pi M_s = 1780$ Gauss. At frequency of 10 GHz and an external magnetic field of $H_0 = 1000$ Oe along the $z$-axis, the components of the permeability of YIG in the $x-y$ plane are $\mu_{\text{dia}} = 0.85$ and $\mu_{\text{off-dia}} = 0.54$. For the nonlinear material, one could use NaN$_3$, which has relative permittivity of $\epsilon = 4.18$ and $\chi^{(2)} = 3.2 \times 10^{-22}$ C V$^{-2}$ at frequency of tens of GHz. Setting the radius of the cylinders to $r = 0.35a$, with $a \approx 3$ mm, the system has topological band gaps at $\omega_0 \in [0.195, 0.23]$ and $\Omega_2 \in [0.385, 0.41]$, so that SHG is achieved in the frequency interval of $\omega_0 \in [0.195, 0.205]$. The effects of material losses and frequency dispersion in a ferrite at microwave frequencies have been discussed in Ref. [25], showing that for YIG, the decay length is around 1300$\alpha$, thus far exceeding practical structural dimensions, and the band gap width slightly decreases by about 6%.

Furthermore, recent advances in different experimental platforms for topological photonics provide a variety of choices available to implement the idea of topologically protected nonlinear frequency mixing processes in diverse photonic systems. More specifically, as nonlinearity exists in many optical materials and is easy to incorporate in an experimental platform, the key task reduces to designing photonic systems with several topological frequency band gaps that can satisfy the frequency and phase matching conditions. Regarding this requirement, we stress that several recent experiments have demonstrated the existence of topological band gaps using coupled waveguides or resonators. In these tight-binding systems, further topological band gaps at higher frequencies can readily be created by considering waveguide or resonance modes at higher frequencies.

In what follows, we outline and briefly discuss several such experimental configurations in which this can potentially be achieved. i) Nonlinear and magnetic metamaterials: magnetism and nonlinearity can be easily implemented using metamaterials which provides an alternative to using regular materials, such as YIG and NaN$_3$ suggested above. For example, to create nonlinear metamaterials, approaches, such as insertion of nonlinear elements, nonlinear host medium, and nonlinear transmission lines are commonly used. Artificial magnetism at optical frequencies can be created using metamaterials based on split-ring resonators. Harmonic generation and topological edge states have also been studied in such types of metamaterials. ii) Graphene plasmonic crystals, in Ref. [59] (see Fig. 3c therein) the existence of topological edge modes within different band gaps of a graphene plasmonic crystal. Moreover, in another study [52] (see Fig. 2a therein) the existence of two Dirac points at the frequencies of 3.4 THz and 6.8 THz has been demonstrated. These Dirac points can be gapped out to form two topological band gaps (ideal for SHG) under an external magnetic field as shown in Ref. [53]. In fact, recently, we have studied the topologically protected four-wave mixing process in a graphene metasurface. iii) Mimicking time-reversal breaking and synthesizing magnetic fields for photons, using an array of evanescently coupled helical waveguides, topological one-way edge states similar to that presented in Fig. 3 can be created without the need of an external magnetic field (see, e.g., Fig. 2b in Ref. [54]. Alternatively, one can also create one-way edge states using synthetic magnetic fields rather than a real magnetic field in an array of coupled optical-ring resonators (e.g., see Fig. 4 in Ref. [55]). Furthermore, additional topological band gaps at higher frequencies can be readily created by considering waveguide modes at corresponding frequencies. iv) Photonic quantum valley Hall (QVH or QSH) crystals with time-reversal symmetry: recent experiments on valley-Hall-like photonic systems have demonstrated the existence of one [56,57] or two [58,59] (see Fig. 2b therein) topological band gaps and corresponding edge modes within the gaps. As for the photonic QSH systems, the experiments in [25, 60, 61] have demonstrated the existence of one topological band gap. Moreover, the proposal in [62] (see Figs. 3 and 4 therein) using optically-passive elements to realize the optical version of the QSH insulator has shown the existence of multiple topological band gaps.
In this work, we have demonstrated topology-protected nonlinear frequency conversion processes via one-way edge modes of topological photonic crystals. Apart from the proof-of-concept implementations, such as SHG and THG, we also showed that more complex behaviors, such as slow-light effects and counter-propagating mode interaction, can also be realized within the setup. A special aspect of nonlinear processes, i.e., the phase-matching condition, requires a new level of control of the edge modes, which has not been discussed previously. This condition requires a method to tune the dispersion of the edge modes, which we found can be conveniently achieved by tailoring the geometry of the edge termination. Our work reveals that the coherence length characterizing the nonlinear optical interactions considered in this study, which crucially determines the efficiency of the topologically protected nonlinear frequency mixing processes, is robust against structural defects. Our proposed setup provides a platform for studying additional phenomena, e.g., when the frequency gap has large Chern number (|C| ≠ 0), one can explore how to excite one of the several edge modes in the gap or how to couple edge modes belonging to different gaps via the nonlinearity of the medium.

Importantly, nonlinear interactions of topological modes, such as sum- and difference-frequency generation, high-harmonic generation, and four-wave-mixing, can be readily implemented within our setup. Our work may also stimulate the search for other lattice geometries or setups where one can optimize the gap properties for specific applications. For example, in the Chern number graded gap phase diagrams of Fig. 2, apart from the gap of C = 1, other gaps with C = −1, −2, 2, 3 are typically narrow and appear at high frequencies, so designing setups where these gaps are wide and are formed at low frequencies is particularly relevant from experimental point of view. Beyond the experimental implementation of our model system at microwave frequencies using magnetic and nonlinear materials, we also discussed several different possible implementations using diverse experimental platforms available for topologic photonics. Last but not least, the concept of topology-protected nonlinear frequency mixing is very general in that it applies not only to photonics, but also to plasmonics, phononics, magnonics, and exciton-polariton systems, thus we expect that our work will have a broad impact.

Appendix A: Computation of Chern numbers

The Chern number of the nth-band of the photonic crystal is defined by Eq. (3), based on Refs.

\[ C_n = \frac{1}{2\pi i} \sum \chi_{12} \alpha \beta \alpha \beta^{(A3)} \]

where \( U_{\alpha\beta}(k_l) \) is a lattice point in the discretized Brillouin zone and \( e_{\alpha} \) is the lattice displacement in the direction \( \alpha (\alpha = 1, 2) \). Furthermore, a lattice field strength can be defined by the link variable:

\[ F_{12}(k_l) = \ln \left| U_1(k_1)U_2(k_2) + (k_1 + e_1)U_1^{-1}(k_1) - (k_2 + e_2)U_2^{-1}(k_2) \right| \]

where the lattice field strength is defined as the principal branch of the logarithm \( -\pi < F_{12}(k_l)/i \leq \pi \). Finally, the Chern number of the nth band can be calculated from the lattice field strength according to:

\[ C_n = \frac{1}{2\pi i} \sum \chi_{12} \alpha \beta \alpha \beta^{(A4)} \]

one can get

\[ C_n = \sum \chi_{12} n_{12}(k_l) \]

which shows that \( C_n \) is an integer. Certainly, this does not mean that any coarse discretization of the first Brillouin zone will ensure a converged Chern number; nevertheless, asymptotic convergence of the Chern number requires only a moderately dense discretization. In our calculations of the data presented in Fig. 2, we find that a 20 × 20 discretization of the first Brillouin zone suffices.

Appendix B: Coupled-mode theory for the third-harmonic generation

The coupled-mode equations for the third-harmonic generation can be derived in a way similar to that for the second-harmonic generation presented in Section III A. Here we outline the main steps. First, one can write down the expressions for the fundamental \( f \) and third \( t \) harmonic waves,
(E^f_1, H^f_1, E^f_2, H^f_2, P^f_{NL}) and (E^f_1, H^f_1, E^f_2, H^f_2, P^f_{NL}) in the following Bloch forms:

\[ E^f_1(r, \omega_0) = \frac{e^f(r, \omega_0)}{\sqrt{P_f}} e^{ik_f(\omega_0)x}, \quad (B1a) \]
\[ H^f_1(r, \omega_0) = \frac{h^f(r, \omega_0)}{\sqrt{P_f}} e^{ik_f(\omega_0)x}, \quad (B1b) \]
\[ E^f_2(r, \omega_3) = \frac{e^f(r, \omega_3)}{\sqrt{P_f}} e^{ik_f(\omega_3)x}, \quad (B1c) \]
\[ H^f_2(r, \omega_3) = \frac{h^f(r, \omega_3)}{\sqrt{P_f}} e^{ik_f(\omega_3)x}, \quad (B1d) \]

and

\[ E^f_2(r, \omega_0) = A_f(x) \frac{e^f(r, \omega_0)}{\sqrt{P_f}} e^{ik_f(\omega_0)x}, \quad (B2a) \]
\[ H^f_2(r, \omega_0) = A_f(x) \frac{h^f(r, \omega_0)}{\sqrt{P_f}} e^{ik_f(\omega_0)x}, \quad (B2b) \]
\[ E^f_2(r, \omega_3) = A_f(x) \frac{e^f(r, \omega_3)}{\sqrt{P_f}} e^{ik_f(\omega_3)x}, \quad (B2c) \]
\[ H^f_2(r, \omega_3) = A_f(x) \frac{h^f(r, \omega_3)}{\sqrt{P_f}} e^{ik_f(\omega_3)x}, \quad (B2d) \]

where \( \Omega_3 = 3\omega_0 \) and \( P^f_{NL}, P^f_{NL} \) can be derived from \( P^f_{NL}(r, t) = \chi^{(3)}(r, t)E(r, t)E(r, t)E(r, t) \) with \( E(r, t) = E^f_2(\omega_0) + E^f_2(\omega_3) \) and \( \chi^{(3)} \) the third-order susceptibility tensor. After some simple algebra, the nonlinear polarizations at the fundamental and third-harmonic frequencies can be written as:

\[ P^f_{NL}(r, \omega_0) = \frac{3A^3_f(x)A_f(x)}{P_f \sqrt{P_f}} \chi^{(3)} e^f(r, \omega_0)e^f(r, \omega_0)e^f(r, \omega_0)e^f(r, \omega_0)e^{ik(2k_f)x}, \quad (B3a) \]
\[ P^f_{NL}(r, \omega_3) = \frac{A^3_f(x)}{P_f \sqrt{P_f}} \chi^{(3)} e^f(r, \omega_3)e^f(r, \omega_3)e^f(r, \omega_3)e^{ik(2k_f)x}. \quad (B3b) \]

If we now consider the fields \( (E^f_1, H^f_1, E^f_2, H^f_2, P^f_{NL}) \), the l.h.s. of Eq. (16) gives:

\[ \int_{-\infty}^{\infty} \nabla \cdot \mathbf{F} dy = \frac{3i\omega_0 A^2_f A_f e^{ik_{\chi}(x)}}{P_f \sqrt{P_f} P_f} \int_{-\infty}^{\infty} \left[ e^f \cdot \chi^{(3)}(\Omega_3) \right] e^f e^f e^f e^f, \quad (B4) \]

where \( \Delta k = k_f(\Omega_3) - 3k_f(\omega_0) \), and the r.h.s. of Eq. (16) leads to:

\[ \frac{\partial}{\partial x} \int_{-\infty}^{\infty} \mathbf{F} \cdot \mathbf{\hat{k}} dy = \frac{\partial}{\partial x} \int_{-\infty}^{\infty} \left[ (E^f_1 - H^f_2) \times H^f_2 + (E^f_2 - H^f_1) \times H^f_1 \right] \cdot \mathbf{\hat{k}} dy \]

Comparing Eqs. (B4) and (B5), we obtain the coupled-mode equation for the slowly-varying mode amplitude \( A_f(x) \):

\[ \frac{dA_f(x)}{dx} = i\gamma_f^{(3)}(x)A_f^2(x)A_f(x)e^{i\Delta k x}, \quad (B6) \]

where the nonlinear coefficient at the fundamental frequency is

\[ \gamma_f^{(3)}(x) = \frac{3\omega_0}{4P_f \sqrt{P_f} P_f} \int_{-\infty}^{\infty} e^f \cdot \chi^{(3)}(\Omega_3) e^f e^f e^f e^f dy. \quad (B7) \]

Similarly, if we consider the fields \( (E^f_1, H^f_1, E^f_2, H^f_2, P^f_{NL}) \), the l.h.s. of Eq. (17) gives:

\[ \int_{-\infty}^{\infty} \nabla \cdot \mathbf{F} dy = \frac{i\Omega_3 A^3_f e^{i\Delta k x}}{P_f \sqrt{P_f} P_f} \int_{-\infty}^{\infty} e^f \cdot \chi^{(3)}(\Omega_3) e^f e^f e^f e^f \]

\[ \quad - \frac{\partial}{\partial x} \int_{-\infty}^{\infty} \mathbf{F} \cdot \mathbf{\hat{k}} dy = \frac{\partial}{\partial x} \int_{-\infty}^{\infty} \left[ (E^f_1 - H^f_2) \times H^f_2 + (E^f_2 - H^f_1) \times H^f_1 \right] \cdot \mathbf{\hat{k}} dy = 4 \frac{dA_f(x)}{dx}, \quad (B8) \]

Finally, from Eqs. (B8) and (B9), we get the coupled-mode equation for the slowly-varying amplitude \( A_f(x) \) as:

\[ \frac{dA_f(x)}{dx} = i\gamma_f^{(3)}(x)A_f^2(x)e^{i\Delta k x}, \quad (B10) \]

where the nonlinear coefficient at the third-harmonic frequency is:

\[ \gamma_f^{(3)}(x) = \frac{\Omega_3}{4P_f \sqrt{P_f} P_f} \int_{-\infty}^{\infty} e^f \cdot \chi^{(3)}(\Omega_3) e^f e^f e^f e^f. \quad (B11) \]

We can also express the nonlinear coefficients in terms of the group indices and the effective third-order susceptibilities, \( X^{(3)}_{eff,f}(x) \), of the two interacting modes:

\[ \gamma_f^{(3)}(x) = \frac{12\omega_0}{a_g^2 \gamma_d f \sqrt{P_f \gamma_d f \gamma_f d}} X^{(3)}_{eff,f}(x), \quad (B12a) \]
\[ \gamma_f^{(3)}(x) = \frac{4\Omega_3}{a_g^2 \gamma_d f \sqrt{P_f \gamma_d f \gamma_f d}} X^{(3)}_{eff,f}(x), \quad (B12b) \]

where
\[ \chi^{(3)}_{\text{eff},f}(x) = \frac{a^3}{(\int_{A_{\text{cell}}} \left( e^* e + Z_0^2 h^* \cdot \mu h \right) dA)^{3/2}} \left[ \int_{A_{\text{cell}}} \left( e^* \cdot \hat{e} f + Z_0^2 h^* \cdot \mu h \right) dA \right]^{1/2} \]

Introducing the averaged physical quantities,

\[ \bar{\gamma}^{(3)}_{f} = \frac{1}{a} \int_{S_{h \omega}} \gamma^{(3)}_{f}(x) dx, \]

\[ \bar{\gamma}^{(3)}_{\text{eff},f} = \frac{1}{a} \int_{S_{h \omega}} \gamma^{(3)}_{\text{eff},f}(x) dx, \]

and then averaging Eqs. (B15) and (B11) over one lattice constant, we obtain the coupled-mode equations governing the nonlinear dynamics of the interacting modes:

\[ \frac{d \bar{A}_f(x)}{dx} = i \bar{\gamma}^{(3)}_{f} \bar{A}_f(x)e^{i\Delta k x}, \]

\[ \frac{d \bar{A}_0(x)}{dx} = i \bar{\gamma}^{(3)}_{0} \bar{A}_0(x)e^{-i\Delta k x}, \]

where \( \bar{A}_f(x) \) and \( \bar{A}_0(x) \) are the averaged mode amplitudes at the fundamental and third-harmonic frequencies, respectively.

---

**Appendix C: Comparison between rigorous numerical simulations and the coupled-mode theory**

In this Appendix, we present a computational analysis that illustrates how the coupled-mode theory derived above can be used to explain the full-wave dynamics obtained using COMSOL.

### 1. Second-harmonic generation described by the coupled-mode theory

The key quantities that characterize the coupled-mode theory describing the second-harmonic generation are \( \chi^{(2)}_{\text{eff},f}(x) \) and \( \chi^{(2)}_{\text{eff},o}(x) \), as defined by Eqs. (B15a) and (B15b), respectively. As we consider photonic crystals that are periodic in space, \( \chi^{(2)}_{\text{eff},f}(x) \) and \( \chi^{(2)}_{\text{eff},o}(x) \) are periodic functions of \( x \), and we only need to show their \( x \)-dependence in one unit cell. Thus, in Fig. 7 we depict the \( x \)-dependence of \( \chi^{(2)}_{\text{eff},f}(x) \) and \( \chi^{(2)}_{\text{eff},o}(x) \) in one unit cell. As one can see, while the real parts of \( \chi^{(2)}_{\text{eff},f}(x) \) and \( \chi^{(2)}_{\text{eff},o}(x) \) for SHG in one unit cell. While the real parts of \( \chi^{(2)}_{\text{eff},f}(x) \) and \( \chi^{(2)}_{\text{eff},o}(x) \) are even functions, with respect to the center of the unit cell, the imaginary parts of \( \chi^{(2)}_{\text{eff},f}(x) \) and \( \chi^{(2)}_{\text{eff},o}(x) \) are odd functions.

---

**FIG. 7.** Real (a, c) and imaginary (b, d) parts of \( \chi^{(2)}_{\text{eff},f}(x) \) and \( \chi^{(2)}_{\text{eff},o}(x) \) of Eq. (27) for SHG in one unit cell. While the real parts of \( \chi^{(2)}_{\text{eff},f}(x) \) and \( \chi^{(2)}_{\text{eff},o}(x) \) are even functions, with respect to the center of the unit cell, the imaginary parts of \( \chi^{(2)}_{\text{eff},f}(x) \) and \( \chi^{(2)}_{\text{eff},o}(x) \) are odd functions.

**FIG. 8.** The evolution of the power of the second-harmonic wave as a function of propagation distance. The red dots are from rigorous full-wave numerical simulations while the black curve is obtained from solving the coupled-mode equations expressed as Eqs. (29).
and $\chi_{eff,f}^{(2)}(x)$ are even functions, with respect to the center of the unit cell, the imaginary parts of $\chi_{eff,f}^{(2)}(x)$ and $\chi_{eff,s}^{(2)}(x)$ are odd functions. In fact, it can be easily demonstrated that $\chi_{eff,f}^{(2)}(x) = \chi_{eff,s}^{(2)}(x)$. Therefore, the averages of $\chi_{eff,f}^{(2)}(x)$ and $\chi_{eff,s}^{(2)}(x)$ in one unit cell are real numbers and are equal to each other.

After one computes $\gamma_{f,s}^{(2)}$ and $\chi_{eff,f/s}^{(2)}$ by averaging $\gamma_{f,s}^{(2)}(x)$ and $\chi_{eff,f/s}^{(2)}(x)$, respectively, in one unit cell, one can straightforwardly solve the coupled-mode equations expressed as Eqs. (29). Thus, we present in Fig. 8 the evolution of the generated second-harmonic wave as a function of propagation distance. It can be seen in this figure that there is a good agreement between the coupled-mode theory and rigorous numerical simulations both in regard of the oscillation period and the amplitude of the power of the second-harmonic wave.

2. Third-harmonic generation described by the coupled-mode theory

Similar to the case of SHG, the key quantities that characterize the coupled-mode theory of third-harmonic generation are $\chi_{eff,f}^{(3)}(x)$ and $\chi_{eff,s}^{(3)}(x)$, as defined by Eqs. (B15). Both these physical quantities are periodic functions of the $x$-coordinate, their $x$-dependence being presented in Fig. 9. Also similar to the case of SHG, while the real parts of $\chi_{eff,f}^{(3)}(x)$ and $\chi_{eff,s}^{(3)}(x)$ are even functions, the imaginary parts of $\chi_{eff,f}^{(3)}(x)$ and $\chi_{eff,s}^{(3)}(x)$ are odd functions. Therefore, the averages of $\chi_{eff,f}^{(3)}(x)$ and $\chi_{eff,s}^{(3)}(x)$ in one unit cell are real numbers and are equal to each other.

We have solved Eqs. (B15) using $\gamma_{f,s}^{(3)}$ obtained by averaging $\gamma_{f,s}^{(3)}(x)$ in one unit cell and present the results in Fig. 10.

![Fig. 9](image-url)  
**Fig. 9.** Real (a, c) and imaginary (b, d) parts of $\chi_{eff,f}^{(3)}(x)$ and $\chi_{eff,s}^{(3)}(x)$ of Eqs. (B15) for THG in one unit cell. Similar to the case of SHG, while the real parts of $\chi_{eff,f}^{(3)}(x)$ and $\chi_{eff,s}^{(3)}(x)$ are even functions, the imaginary parts of $\chi_{eff,f}^{(3)}(x)$ and $\chi_{eff,s}^{(3)}(x)$ are odd functions.

![Fig. 10](image-url)  
**Fig. 10.** The evolution of the power of the third-harmonic wave vs. propagation distance. The red dots are from numerical simulations while the black curve is from solving Eqs. (B15).

We again find a good agreement between the coupled-mode theory and rigorous numerical simulations regarding both the oscillation period and amplitude of the power of the third-harmonic wave.

3. Coupled-mode theory of slow-light nonlinearity enhancement

The group index $n_g$ of the edge modes in a generic case, e.g., Fig. 4 is limited to 5–7. However, we have shown in the main text that the shape of the dispersion curve of the one-way edge modes can be tailored, leading to much larger $n_g$, as per Fig. 9. As it is well known, this will enhance the efficiency of the nonlinear process. We plot in Fig. 11 the function $\chi_{eff,f}^{(2)}(x)$ at two different frequencies, $\tilde{\omega}_{slow} = 0.197$ and $\tilde{\omega}_{fast} = 0.21$ with $n_g^{(2)}(\tilde{\omega}_{slow}) \approx 174$ and $n_g^{(2)}(\tilde{\omega}_{fast}) \approx 12$ [5] $n_g^{(2)}(\tilde{\omega}_{slow}) \approx 4$ and $n_g^{(2)}(\tilde{\omega}_{fast}) \approx 4$ have similar values at these frequencies.

![Fig. 11](image-url)  
**Fig. 11.** (a) $\chi_{eff,f}^{(2)}(x)$ defined by Eqs. (22) for SHG in one unit cell at two different frequencies, $\tilde{\omega}_{slow} = 0.197$ and $\tilde{\omega}_{fast} = 0.21$, where the group indices of the fundamental wave at the two frequencies are $n_g^{(2)}(\tilde{\omega}_{slow}) \approx 174$ and $n_g^{(2)}(\tilde{\omega}_{fast}) \approx 12$ [5] $n_g^{(2)}(\tilde{\omega}_{slow}) \approx 4$ and $n_g^{(2)}(\tilde{\omega}_{fast}) \approx 4$. (b) The nonlinear coefficient $\gamma_{f,s}^{(3)}(x)$ of Eqs. (21) in one unit cell at the two frequencies $\tilde{\omega}_{slow}$ and $\tilde{\omega}_{fast}$. One can see the enhancement of the nonlinear coefficient due to the slow-light effect $n_g^{(2)}(\tilde{\omega}_{slow})/n_g^{(2)}(\tilde{\omega}_{fast}) \approx 15$, whereas $\gamma_{f,s}^{(3)}(\tilde{\omega}_{slow})/\gamma_{f,s}^{(3)}(\tilde{\omega}_{fast}) \approx 18$ according to Eq. (28).
two frequencies. While the amplitudes of $\chi^{(2)}_{f_1f_2f_3}(x)$ at these two frequencies are comparable, from Fig. 11b, which shows the nonlinear coefficient $\gamma^{(2)}_{f_1f_2}(x)$ of Eqs. (21)/(25), one can see that $\gamma^{(2)}_{f_1}(x)$ at $\omega_{\text{slow}}$ is significantly enhanced as compared to $\gamma^{(2)}_{f_2}(x)$ at $\omega_{\text{fast}}$. The ratio of the averaged nonlinear coefficient in one unit cell according to Eq. (28) and Fig. 5b is $\gamma^{(2)}_{f_1}(\omega_{\text{slow}})/\gamma^{(2)}_{f_2}(\omega_{\text{fast}}) \approx 18$, which roughly agrees with $n_{g}^{(2)}(\omega_{\text{slow}})/n_{g}^{(2)}(\omega_{\text{fast}}) \approx 15$. This enhancement of the nonlinear coefficient leads to the enhancement of the efficiency of the SHG, see, e.g., Figs. 5a and 5b.
