Exosomes from human induced pluripotent stem cells-derived keratinocytes accelerate burn wound healing through miR-762 mediated promotion of keratinocytes and endothelial cells migration

Yunyao Bo†, Lijun Yang†, Baiting Liu, Guiping Tian, Chenxi Li, Lin Zhang¹,²,³* and Yuan Yan¹,²,³*

Abstract

Background: The use of keratinocytes derived from induced pluripotent stem cells (iPSCs-KCs) may represent a novel cell therapy strategy for burn treatment. There is growing evidence that extracellular vesicles, including exosomes, are primary mediators of the benefits of stem cell therapy. Herein, we thus explored the effects of exosomes produced by iPSCs-derived keratinocytes (iPSCs-KCs-Exos) in a model of deep second-degree burn wound healing and evaluated the mechanistic basis for the observed activity.

Methods: iPSCs-KCs-Exos were isolated from conditioned medium of iPSCs-KCs and verified by electron micrograph and size distribution. Next, iPSCs-KCs-Exos were injected subcutaneously around wound sites, and its efficacy was evaluated by measuring wound closure areas, histological examination, and immunohistochemistry staining. The effects of iPSCs-KCs-Exos on proliferation and migration of keratinocytes and endothelial cells in vitro were assessed by EdU staining, wound healing assays, and transwell assay. Then, high-throughput microRNA sequencing was used to explore the underlying mechanisms. We assessed the roles of miR-762 in iPSCs-KCs-Exos-induced regulation of keratinocytes and endothelial cells migration. Furthermore, the target gene which mediated the biological effects of miR-762 in keratinocytes and endothelial cells was also been detected.

Results: The analysis revealed that iPSCs-KCs-Exos application to the burn wound drove the acceleration of wound closure, with more robust angiogenesis and re-epithelialization being evident. Such iPSCs-KCs-Exos treatment effectively enhanced endothelial cell and keratinocyte migration in vitro. Moreover, the enrichment of miR-762 was detected in iPSCs-KCs-Exos and was found to target promyelocytic leukemia (PML) as a means of regulating cell migration through a mechanism tie to integrin beta1 (ITGB1).

Conclusion: These results thus provide a foundation for the further study of iPSCs-KCs-Exos as novel cell-free treatments for deep second-degree burns.

Introduction
Burns is a form of serious traumatic injury that causes substantial global morbidity, and there is thus an urgent need to define novel approaches to expediting burn healing [1–3]. Preclinical and clinical evidence suggests that keratinocyte-based therapies offer great promise in the context of burn management [4–6]. However, there are substantial challenges to large-scale keratinocyte preparation efforts because donor keratinocyte yields are often very limited. The ability of these donated cells to proliferate and differentiate in vitro is also highly variable. The Yamanaka lab first developed induced pluripotent stem cells (iPSCs) and highlighted their potential as a novel source of many cellular lineages for use in therapeutic contexts [7–9]. The generated iPSCs are extremely similar to embryonic stem cells being capable of generating all cell lineages of different tissues including skin, highlighting a novel method of improving cell-based wound treatment efforts while minimizing ethical concerns and the risk of immune-mediated graft rejection [10, 11].

We have previously shown that iPSCs-derived keratinocytes (iPSCs-KCs) hold great promise for treating wound healing [12, 13]. However, the safety profile of these cells is not known and they are potentially limited by the risk of immunogenicity and genetic instability. Recent work has suggested that small membrane-bound exosomes derived from cells can facilitate a substantial fraction of the paracrine signaling necessary to facilitate intracellular communication [14, 15]. Exosomes of stem cells including bone marrow mesenchymal stem cells, human amniotic epithelial cells, and iPSCs can play an anti-inflammatory and anti-fibrosis role, inhibit oxidative stress and enhance angiogenesis, thus promoting skin wound healing [16–20]. As such, we speculate that iPSCs-KCs-derived exosomes (iPSCs-KCs-Exos) have the potential to play a direct role in the facilitation of burn wound healing. Up to now, there are no related studies on the iPSCs-KCs-Exos, and there are few studies on the primary keratinocyte’s exosomes in skin wound healing [21–23].

Herein, we utilized iPSCs-KCs-Exos to treat murine skin wounds to test the therapeutic efficacy of these cell-free vesicles. We found that such iPSCs-KCs-Exos treatment was conducive to more rapid wound closure as well as enhanced endothelial cell and keratinocyte migration. We then evaluated the microRNAs present within these exosomes to identify important mediators of this wound healing phenotype and found miR-762 to be highly enriched in iPSCs-KCs-Exos and to serve as an important mediator of cellular migration owing to its ability to target PML. Overall, these data highlight the important roles played by iPSCs-KCs-Exos and miR-762 in the treatment of cutaneous wounds.

Materials and methods
Cell culture
The human iPS cell line was provided by Stem Cell Bank, the Chinese Academy of Sciences. hiPSCs were cultured on Matrigel (BD Biosciences, CA) in mTeSR™1 medium (Stemcell Technologies, CA) and passed
every 4–7 days. hiPSCs were induced to keratinocytes as described previously [11]. Briefly, hiPSCs were switched to unconditioned medium (UM) supplemented with retinoic acid (RA): DMEM/F12 containing 20% knockout serum replacer, 1 mM L-glutamine, 1 × MEM nonessential amino acids, 0.1 mM β-mercaptoethanol (all from Life Technologies, USA) and 1 mM all-trans RA (Sigma-Aldrich, USA). Cells were cultured in UM + RA for 7 days, changing medium daily. On day 8, cells were passaged for 72 h, embedded in paraffin, and then cut into 5 mm thick sections. The sections were stained with hematoxylin–eosin (H&E) staining (Leagene, China) and Masson’s tri-chrome staining (MXB Biotechnologies, China). The re-epithelialization was calculated in the accordance with the formula [a distance of the re-epithelium]/ [a distance of the wound] × 100.

**Immunohistochemical assay**

Tissue sections for immunohistochemical staining were dewaxed, incubated with 3% H2O2, and heated with citrate buffer (pH 6.0). After being blocked by goat serum, sections were incubated overnight with CD31 primary antibody (Abcam, UK) at 4 °C. The sections were then incubated for 1 h with biotinylated secondary antibodies (Zhong Shan Golden Bridge Biotechnology, China). Peroxidase activity was detected by diaminobenzidine (DAB). Finally, sections were counterstained with hematoxylin.

**Immunofluorescence assay**

At room temperature, cells were fixed with 4% paraformaldehyde for 30 min and then drilled with 0.5% Triton X-100 for 15 min. The cells were incubated overnight at 4 °C with primary antibodies against K14, loricrin, or involucrin (Proteintech, USA) and then incubated with Alexa Fluor 647-conjugated sheep anti-rabbit secondary antibody (Abcam, UK) at 4 °C. The sections were then dewaxed, incubated with 3% H2O2, and heated with citrate buffer (pH 6.0). After being blocked by goat serum, sections were incubated overnight with biotinylated secondary antibodies (Zhong Shan Golden Bridge Biotechnology, China). Peroxidase activity was detected by diaminobenzidine (DAB). Finally, sections were counterstained with hematoxylin.

**Treatment of deep second-degree burns**

The 8-week-old C57BL/6 mice were purchased from the Experimental Animal Center of Southern Medical University. After the hair removal from the back of the mice, the opening at one end of a cylindrical plastic tube with a diameter of 1.5 cm was affixed to the back skin of the mice. Then pour boiling water into the tube at a height of 2 cm and then the tube was removed after 18 s. After burning, local subcutaneous injections of PBS or exosomes were given to the wound site.

**Extraction and identification of iPSCs-KCs-Exos**

iPSCs-KCs were cultured in K-DSFM for 48 h. After collecting the supernatant, exosomes were isolated and purified by serial ultracentrifugation, using ultracentrifuge (Beckman, Germany). Briefly, the supernatant was centrifuged at 300 × g for 10 min, 2000 × g for 10 min, then 10,000 × g for 30 min at 4 °C to remove cells and debris. The supernatants were then centrifuged at 100,000 × g for 70 min at 4 °C. Applying PBS to resuspend the pellet and centrifuged again at 100,000 × g for 70 min. Finally, the exosomes were re-suspended in PBS. The concentration of exosomes was measured by Enhanced BCA Protein Assay Kit (Beyotime, China). Then, transmission electron microscopy (TEM) was used to observe the morphological structure of exosomes. Size distribution and concentration of iPSCs-KCs-Exos were analyzed by nanoparticle tracking analysis (NTA) using Nanosight LM 10 (Malvern Pananalytical, UK).

**Histological observations**

The skin tissues were fixed with 4% paraformaldehyde for 72 h, embedded in paraffin, and then cut into 5 mm
24 h incubation at 5% CO₂ and 37 °C, the cells were fixed with 4% paraformaldehyde. The cells at the lower side of the membrane were stained with Crystal Violet Staining Solution (Beyotime China) for 15 min. An inverted microscope (Leica, Germany) randomly collected 10 images from each sample.

miRNA microarray analysis
miRNA microarray analysis was performed by Epibiotek (Guangzhou, China) as previously described [19].

Western blot analysis
The Western blot assay was performed as previously described [19]. Antibodies used were described as follows: anti-PML, anti-ITGB1 or anti β-actin (all from Abcam, UK).

Reverse transcription-quantitative polymerase chain (qRT–PCR)
Trizol™ reagent (Invitrogen, USA) was used to extract the total RNA from cells, according to the manufacturer’s instructions. RNA was reverse-transcribed using Rever-tAid First Strand cDNA Synthesis Kit (Thermo Scientific, USA). qRT–PCR analysis was using AECQ Universal SYBR qPCR Master Mix (Vazyme, China). Midtect A TrackTM miRNA qRT–PCR Starter Kit (RiboBio, China) was used for the synthesis of miRNA cDNA. Then, Midtect A TrackTM miRNA qRT–PCR Starter Kit (RiboBio, China) was used for qRT–PCR.

Luciferase report assay
The wild type and mutant miR-762 binding sites of PML 3’UTR sequence were subcloned into psiCHECK-2 vector. MiR-762 mimics or negative control mimics were co-transfected with recombinant plasmid into HEK-293 T cells using Lipofectamine 2000 (Invitrogen, USA). According to the manufacturer’s instructions, the Firefly and Renilla luciferase activities were detected by Dual Luciferase Reporter Gene Assay Kit (Beyotime, China).

Statistical analysis
Data were presented as mean ± standard deviation (SD) of at least three independent experiments (n ≥ 3). Statistical analysis was performed by independent samples t-test for comparison between two groups or one-way ANOVA among the groups. p < 0.05 was considered statistically significant.

Results
Characterization of iPSCs-KCs and iPSCs-KCs-Exos
To characterize prepared iPSCs-KCs, we conducted immunohistochemical (IHC) staining for cytokeratin-14 (K14), which is a keratin marker confirming the commitment of the ectoderm to a keratinocyte fate. As shown in Fig. 1A, K14 was detectable in iPSCs-KCs. In addition, these K14+ cells expressed involucrin and loricrin (Fig. 1B), markers of terminal epidermal differentiation, after induced differentiation in a high calcium medium (1.5 mM CaCl₂), indicating that these iPSCs-KCs have the ability of epidermal differentiation.

Next, iPSCs-KCs-Exos preparations were obtained by ultracentrifuging iPSCs-KCs culture supernatants (Fig. 1C) and analyzing them via transmission electron microscopy (TEM), revealing the presence of exosomes with the expected cup-shaped morphology (Fig. 1D). Nanoparticle tracking analysis (NTA) revealed these particles to have an average diameter of 75 nm (Fig. 1E). All these data suggested that these nanoparticles were actually exosomes.

iPSCs-KCs-Exos treatment accelerates the healing of deep second-degree burns in mice
To test the effects of iPSCs-KCs-Exos treatment on the healing of burn wounds, deep second-degree burns were generated in the abdominal skin of model mice, after which iPSCs-KCs-Exos or an equivalent volume of PBS was locally injected into these areas. Beginning on day 7 post-wounding, significant decreases in wound area in the iPSCs-KCs-Exos group were evident relative to the PBS group, and these improvements grew through day 11 (Fig. 2A). This suggests that iPSCs-KCs-Exos can promote the acceleration of cutaneous wound repair in vivo.

We additionally conducted histological analyses of these healing wounds. Improved re-epithelialization of the wound site was observed in the iPSCs-KCs-Exos treatment group on days 7 and 11 after wounding as compared to the control group when H&E staining was conducted (Fig. 2B, C). Furthermore, there was a significant increase in the length of epithelial tongues on days 7 and 11 in the iPSCs-KCs-Exos group compared to the PBS group (Fig. 2B, D). Immunohistochemical staining for CD31 further revealed that significant improvements in capillary density were evident in the iPSCs-KCs-Exos-treated wounds. (Fig. 2E). However, no differences in collagen deposition were observed when comparing iPSCs-KCs-Exos and PBS groups (Fig. 2F). Together, these data revealed a role for iPSCs-KCs-Exos as drivers of re-epithelialization and angiogenesis, thereby enabling them to accelerate the wound healing process.

iPSCs-KCs-Exos promote the migration of keratinocytes and endothelial cells in vitro
To better elucidate the mechanisms whereby iPSCs-KCs-Exos treatment can accelerate the burn wound healing, the impact of these exosomes on healing-related cell types (endothelial cells and keratinocytes)
was next assessed. EdU assays were applied to determine the effect of iPSCs-KCs-Exos on the proliferation of these two kinds of cells. HaCaT cells, a well-established immortalized human keratinocyte cell line, and human umbilical vein endothelial cells (HUVECs) were used in this study. As shown in Fig. 3A and B, these iPSCs-KCs-Exos did not alter the proliferation of HaCaT cells or HUVECs at all doses in vitro. In a wound healing assay, iPSCs-KCs-Exos treatment was associated with a significantly increased wound closure rate compared to PBS at doses of 1, 2, and 4 μg/ml (Fig. 3C). When evaluated using Transwell assays, HUVECs migratory activity was also found to be significantly increased following iPSCs-KCs-Exos treatment at doses of 1, 2, and 4 μg/ml (Fig. 3D). As such, iPSCs-KCs-Exos can enhance the migration of endothelial cells and keratinocytes migration without altering the proliferative activity of these cells.

miR-762 is enriched within iPSCs-KCs-Exos and serves as a key mediator of iPSCs-KCs-Exos-induced migration of keratinocytes and endothelial cells

While microRNAs (miRNAs) account for a relatively small fraction of the total content within extracellular vesicles, they have nonetheless been shown to be important modulators of cellular function [24]. To test the potential relevance of such miRNAs in the context of iPSCs-KCs-Exos-induced migratory activity and wound healing, miRNA microarray analysis was conducted using these exosomes. The result showed that miR-762 was the most abundant miRNA among these detected miRNAs (Table 1). Thus, we focused on exosomal miR-762 for the next investigation. In a wound healing assay with HaCaT cells, the overexpression of miR-762 resulted in enhanced wound closure rates at 24 h post-wounding (Fig. 4A). To further confirm the functional importance of this miRNA, iPSCs-KCs-Exos-treated HaCaT cells

were treated with a specific inhibitor of miR-762, which attenuated this enhanced migratory activity (Fig. 4A). The same effect was also observed in HUVECs (Fig. 4B). In addition, the expression of miR-762 in HaCaT cells and HUVECs was indeed significantly elevated at 48 h post-iPSCs-KCs-Exos treatment, confirming the ability of these exosomes to deliver miR-762 to recipient cells (Fig. 4C). These data thus suggest that miR-762 is an important mediator of iPSCs-KCs-Exos-induced migration of keratinocyte and endothelial cells in vitro.

miR-762 targets PML to regulate the migratory activity of keratinocytes and endothelial cells through ITGB1
To further clarify the regulatory role of iPSCs-KCs-Exos-derived miR-762 in the context of wound healing, potential target genes for this miRNA were next
identified using the Targetscan, miRDB, and microRNA.org databases. This approach identified PML as a putative target of this miRNA. To confirm this prediction, luciferase reporter constructs containing wild-type (WT) or mutated (MUT) versions of the putative miR-762 binding site located within the PML 3′-untranslated region (UTR) were prepared (Fig. 5A). When 293T cells were transfected with these reporters and miR-762 mimics, this miRNA was confirmed to suppress the activity of the WT but not the MUT reporter, confirming the predicted regulatory relationship (Fig. 5B). Moreover, mRNA and protein levels of PML were significantly lower in HaCaT cells and HUVECs following miR-762 mimic or iPSCs-KCs-Exos treatment (Fig. 5C, D). PML is thus a direct miR-762 target gene. To further examine the link between PML downregulation and the effects of miR-762 and iPSCs-KCs-Exos on the migration of keratinocytes and endothelial cells, the PML was overexpressed with the pcDNA3.1 vector. As shown in Fig. 5E, overexpression of PML inhibited the migration of HaCaT cells and could restrain the cell migration that was promoted by miR-762 mimics or iPSCs-KCs-Exos. Similar results were also observed in HUVECs (Fig. 5F). Taken together, the above results suggest that miR-762 and iPSCs-KCs-Exos induced acceleration of keratinocytes and endothelial cells are mediated at least partly by inhibiting PML expression.

### Table 1

### Discussion

Herein, we found that iPSCs-KCs-Exos treatment was sufficient to promote keratinocyte migration and thereby accelerate the healing of deep second-degree burn wounds in mice. We additionally determined that the most abundant miRNA within these exosomes, miR-762, was a key mediator of this enhanced migratory effect owing to its ability to target PML.

In recent years, a variety of bioactive materials have been developed, which play a role in activating platelets, regulating the chemotaxis of immune cells, and accelerating cell migration and proliferation, respectively, according to the cellular and molecular mechanisms at each stage of wound healing [26]. For example, Li et al. designed an injectable nanocomposite by inserting quaternized carboxymethyl chitosan into the middle layer of organic rectorite, which allowed natural clay to combine with blood cells to achieve hemostasis [27]. A modular hydrogel consisting of a glycosaminoglycan heparin derivative and a star-shaped polyethylene glycol has been designed to maximize the sequestration of chemokines and thus reduce the migration activity of neutrophils and monocytes to the wound area [28]. A type of electrospinning nanofiber scaffold containing nagelschmidtite (NAGEL, Ca7P2Si2O16) has been shown to activate epithelial-mesenchymal transition and endothelial-mesenchymal transition, thereby promoting the process of epithelialization [29]. In addition, exosomes have also been proved to be a kind of biomaterial with great potential for wound therapy [30].

In the process of wound healing, keratinocytes, fibroblasts, and endothelial cells are the main cell populations involved in re-epithelialization and granulation of tissue construction [31]. Therefore, communication between
these cells plays a key role in skin repair. This network is likely regulated by cell-derived exosomes, which carry a range of macromolecular cargos that can be delivered to target cells, enabling them to regulate recipient cell responses in a variety of complex manners [32–35]. Both HaCaT cells and primary keratinocytes can release exosomes and other extracellular vesicles [36, 37]. In their deep sequencing analysis of microRNAs within keratinocyte-derived extracellular vesicles, Than et al. found that the most enriched miRNAs found therein were linked to key physiological processes such as fibroblast migration and dermal-epithelial wound healing, suggesting a role for these vesicles in the context of cutaneous wound healing [21].

This study was designed to explore the ability of iPSC-KC-derived exosomes to regulate the process of burn wound healing. We successfully generated and characterized iPSCs-KCs-Exos, which were of the expected size and exhibited characteristic morphological features. Cutaneous wound healing processes are complicated and necessitate interplay between inflammatory, angiogenic, remodeling, proliferative, epithelialization, and fibrotic processes [38]. Histological analyses revealed that increases in re-epithelialization and capillary density were evident in wound sites following iPSCs-KCs-Exos treatment, but collagen formation was not affected. Thus, we then further examined the effects of these exosomes on endothelial cells and keratinocytes, which are the key

C qRT–PCR analysis of miR-762 expression in HaCaT cells and HUVECs which were treated with iPSCs-KCs-Exos (2 μg/mL) for 24 h. *P < 0.05, **P < 0.01
mediators of angiogenesis and epithelialization, respectively. These analyses revealed that iPSCs-KCs-Exos significantly enhanced the migratory activity of these cells without impacting their proliferative activity. As such, the beneficial impact of these exosomes in the context of cutaneous wound healing may be primarily attributable to their ability to promote keratinocyte and endothelial cell migration.

Exosomes contain a variety of miRNAs, mRNAs, lipids, and proteins that are compiled within the ExoCarta.
Of these, miRNAs are the best-studied exosomal cargos owing to their ability to regulate target mRNA expression. Herein, we detected many miRNAs that were highly abundant within iPSCs-KCs-Exos, of which miR-762 was detected at the highest levels. Moreover, we found that miR-762 was able to promote endothelial cell and keratinocyte migration in a manner similar to iPSCs-KCs-Exos treatment, suggesting that it is
likely a primary mediator of the phenotypic effects-KCs-Exos in the context of wound healing. In prior research, miR-762 has been found to regulate a range of target genes in different contexts. The upregulation of miR-762 in non-small cell lung cancer, bladder cancer, breast cancer, and nasopharyngeal carcinoma has been linked to enhanced tumor cell invasivity, migration, and proliferation [39–42]. However, there have been no prior studies regarding the role of this specific miRNA in keratinocytes or endothelial cells. In line with these past findings, we observed a pro-migratory role for miR-762 in both of these cell types.

Herein, we identified promyelocytic leukemia (PML) as a novel miR-762 target gene associated with the ability of this miRNA to regulate endothelial cell and keratinocyte migration. PML plays a role in many important cellular processes, including tumor suppression, apoptosis, transcriptional regulation, DNA damage response, senescence, and viral defense mechanisms [43–45]. Herein, we confirmed that PML was a direct miR-762 target, and we found that overexpressing PML was sufficient to reverse the beneficial impact of miR-762 on cellular migration. In prior reports, the ability of PML to suppress the migration of MDA-MB-231 cells was attributed to its ability to promote ITGB1 downregulation [25]. ITGB1 is important for attachment to and integrity of cell-extracellular matrix (BME) interaction by mediating binding to BME components, and they are generally required for migration of keratinocytes and endothelial cells [46, 47]. We thus explored the link between ITGB1 and this miR-762/PML regulatory axis, leading us to conclude that PML overexpression suppressed ITGB1 expression while miR-762 was able to reverse this effect. We further confirmed a role for ITGB1 in the miR-762/PML-mediated migratory phenotypes observed in this experimental system. However, as miRNAs target multiple genes, these results do not offer any insight into the ability of miR-762 to regulate other signaling pathways within keratinocytes. Moreover, while PML and ITGB1 clearly play a role in this process, further work is required to elucidate the underlying mechanisms.

In conclusion, these results indicate that iPSCs-KCs-Exos treatments can significantly improve burn wound healing outcomes, highlighting novel approaches to expediting cutaneous wound healing and providing a foundation for future research efforts. There are also some limitations of this study. We only tested the effect of iPSCs-KCs-Exos on keratinocytes and endothelial cells, so more research is needed in the future to explore the possibility of iPSCs-KCs-Exos affecting other different cell types during all phases of wound healing. For clinical application, a more efficient and economical generation of keratinocytes from iPSCs needs to be developed. As with other types of exosomes, advances in large-scale production technology and quality control of exosomes will enhance the use of iPSCs-KCs-Exos in wound healing applications in the near future.
