Multifunctions of Bounded Variation  
Preliminary Version I  

R. B. Vinter*  

November 4, 2014  

Abstract  
Consider control systems described by a differential equation with a control  
term or, more generally, by a differential inclusion with velocity set $F(t, x)$.  
Certain properties of state trajectories can be derived when, in addition to  
other hypotheses, it is assumed that $F(t, x)$ is merely measureable w.r.t. the  
time variable $t$. But sometimes a refined analysis requires the imposition of  
stronger hypotheses regarding the $t$ dependence of $F(t, x)$. Stronger forms of  
necessary conditions for state trajectories that minimize a cost can derived,  
for example, if it is hypothesized that $F(t, x)$ is Lipschitz continuous w.r.t. $t$.  
It has recently become apparent that interesting addition properties of state  
trajectories can still be derived, when the Lipschitz continuity hypothesis is  
replaced by the weaker requirement that $F(t, x)$ has bounded variation w.r.t. $t$.  
This paper introduces a new concept of multifunctions $F(t, x)$ that have  
bounded variation w.r.t. $t$ near a given state trajectory, of special relevance  
to control system analysis. Properties of such multifunctions are derived Their  
significance of illustrated by an application to sensitivity analysis.  

Keywords: Necessary Conditions, Optimal Control, Differential Inclusions, State Constraints.
1 Introduction

A widely used framework for control systems analysis is based on a description of the dynamic constraint in the form of a differential inclusion

$$\dot{x}(t) \in F(t, x(t)) \quad \text{a.e. } t \in [S, T],$$

in which $F: (., .) : [S, T] \times \mathbb{R}^n \to \mathbb{R}^n$. We refer to absolutely continuous functions $x(\cdot) : [S, T] \to \mathbb{R}^n$ as state trajectories.

It is well known that the assumptions that are made regarding the $t$ dependence of $F(t, x)$ have a critical effect on the qualitative properties of the set of state trajectories and, if state trajectories minimizing a given cost function are of primary interest, the assumptions effect the regularity properties of the value function, the nature of necessary conditions that can be derived, etc. In past research on the distinct properties of state trajectories, depending on the different assumptions that are made about the regularity of $F(t, x)$ with respect to $t$, attention has focused on consequences of hypothesizing:

(a): $t \to F(t, x)$ is measurable, or

(b): $t \to F(t, x)$ is Lipschitz continuous.

Examples of distinctions are as follows. It is possible to show that

(i): standard necessary conditions of optimality, in state-constrained optimal control, take a non-degenerate form, under the assumption that $F(\cdot, x)$ is Lipschitz continuous and other assumptions, but this is no longer in general the case if $F(\cdot, \cdot)$ is merely measurable [13, Thm. 10.6.1].

(ii): Optimal state trajectories have essentially bounded derivatives under the assumption that $F(\cdot, x)$ is Lipschitz continuous and other assumptions, but may not be essentially bounded if $F(\cdot, \cdot)$ is merely measurable [8].

(iii): The Hamiltonian evaluated along the an optimal state trajectory and co-state arc cannot contain jumps if $F(\cdot, x)$ is Lipschitz continuous, but may be discontinuous if $F(\cdot, \cdot)$ is merely measurable [6].

Other examples where there are significant differences in the implications of the two kinds of regularity assumptions arise in the study of regularity properties of the value function for state constrained optimal control problems [3], validity of necessary conditions of optimality for free-time optimal control problems [6], the interpretation of costate arcs as gradients of the value function [2] and in more general sensitivity analysis.

Are there other classes of differential inclusions $F(t, x)$, defined by their regularity w.r.t. $t$, where interesting distinctions arise? It turns out that $F(t, x)$’s having
bounded variation w.r.t. \( t \) is an example of such a class. Many properties of the set of state trajectories that are valid when \( F(t, x) \) has Lipschitz dependence, but not in general when \( F(t, x) \) has measurable \( t \) dependence, have analogues when \( F(t, x) \) has bounded variation w.r.t. \( t \).

How should we define ‘\( F(t, x) \) has bounded variation w.r.t. \( t \)’? An obvious approach is to require:

\[
\sup \left\{ \sum_{i=0}^{N-1} \sup_{x \in X} d_H(F(t_{i+1}, x), F(t_i, x)) \right\} < \infty .
\]

(1.2)

Here, \( X \) is some suitably large subset of \( \mathbb{R}^n \). \( d_H(., .) \) denotes the Hausdorff distance between sets. The outer supremum is taken over all possible partitions \( \{t_0 = S, \ldots, t_N = T\} \) of \([S, T]\). But we follow a more refined approach, for reasons that we now describe.

In the study of the implications of regularity assumptions regarding the \( t \)-dependence of \( F(t, x) \), interest usually focuses on a particular state trajectory \( \bar{x}(.) \) (typically a state trajectory minimizing a given cost function). We can expect that, in such situations, properties of \( F(., .) \) only on some neighborhood of the graph of \( \bar{x}(.) \) would be relevant to the ensuing control systems analysis. One way to take account of the special trajectory \( \bar{x}(.) \) would be to let \( X \) in (1.2) be a closed set which contained all possible values of \( \bar{x}(t) \), i.e.

\[
\{ \bar{x}(t) \mid t \in [S, T] \} \subset X \text{ for all } t \in [S, T].
\]

This approach involves making unnecessary assumptions about values of \( F(., .) \) at points far from the graph of \( \bar{x}(.) \). We therefore adopt a more refined definition of bounded variation multifunctions, in which the inner suprema in (1.2) are taken, not over \( X \), but over smaller sets (defined by a parameter \( \delta > 0 \)) and the outer supremum is taken over partitions of \([S, T]\) that have diameter (‘mesh size’) not greater than \( \epsilon > 0 \). Accordingly, we say that \( t \to F(t, .) \) has bounded variation along \( \bar{x}(.) \) if, for some \( \delta > 0 \) and \( \epsilon > 0 \) we have

\[
\sup \left\{ \sum_{i=0}^{N-1} \sup_{x \in \bar{x}(t) + \delta B, t \in [t_i, t_{i+1}]} d_H(F(t_{i+1}, x), F(t_i, x)) | \text{diam } \{t_i\} \leq \epsilon \right\} < \infty.
\]

(1.3)

We also add another refinement; that is to consider multifunctions \( F(t, x, a) \), whose argument includes an additional variable \( a \) that ranges over given subset \( A \) of a finite dimensional linear space. Including the parameter \( a \) provides useful flexibility for certain applications [11].

The purpose of this paper is to bring together and prove properties (relevant to control system analysis) of a multifunction that has bounded variation along some given state trajectory \( \bar{x}(.) \), and of the associated cumulative variation function. These include one-sided continuity properties of such multifunctions and the effects on the cumulative variation function of changes to the multifunction. In the case of a function \( t \to m(t, .) \) of bounded variation along \( \bar{x}(.) \) (a function can be regarded as
a special case of a multifunction), it is shown that there is an associated signed Borel measure. Finally, we show how this theory can be used to obtain new sensitivity formulae describing how the output of a control system is affected by a small time delay in the implementation of a control.

The analysis in this paper generalizes some aspects of the classical theory of functions of a scalar variable having bounded to variation, to allow for several independent variables, when the bounded variation property pertains only to one of the variables, and when multifunctions replaces functions. There is extensive recent work, treating the properties of bounded variation functions with several independent variables, for which the monograph [1] is a comprehensive source of references. The motivation arises from a desire to investigate regularity properties of minimizers of variational problems in several independent variables and of solutions to Hamilton Jacobi equations arising in optimal control (see, for example, [4]). Multi-functions $F(t)$ of a single variable $t$ (no $x$-dependence) possessing a one-sided bounded variation property have been investigated by Moreau [10], in connection with sweeping processes. But the study initiated in this paper, of multifunctions that are $x$-dependent and have bounded variation ‘near’ a given state trajectory $\bar{x}(\cdot)$, is an apparently new departure.

**Notation:** For vectors $x \in \mathbb{R}^n$, $|x|$ denotes the Euclidean length. $B$ denotes the closed unit ball in $\mathbb{R}^n$. Given a multifunction $\Gamma(\cdot) : \mathbb{R}^n \rightrightarrows \mathbb{R}^k$, the graph of $\Gamma(\cdot)$, written $\text{Gr}\{\Gamma(\cdot)\}$, is the set $\{(x, v) \in \mathbb{R}^n \times \mathbb{R}^k | v \in \Gamma(x)\}$. Given a set $A \subset \mathbb{R}^n$ and a point $x \in \mathbb{R}^n$, we denote by $d_A(x)$ the Euclidean distance of a point $x \in \mathbb{R}^n$ from $A$:

$$d_A(x) := \inf\{|x - y| | y \in A\}.$$

$\text{co} A$ denotes the convex hull of a set $A \subset \mathbb{R}^n$. Given an interval $I$, we write $\chi_I(t)$ for the indicator function of $I$, taking values 1 and 0 when $t \in I$ and $t /\notin I$, respectively.

A function $r : [S, T] \to \mathbb{R}$ of bounded variation on the interval $[S, T]$ has a left limit, written $r(t^-)$, at every point $t \in (S, T]$ and a right limit, written $r(t^+)$, at every point $t \in [S, T)$. We say $r(\cdot)$ is normalized if it is right continuous on $(S, T)$.

We denote by $\text{NBV}^+[S, T]$ the space of increasing, real-valued, normalized functions $\mu(\cdot)$ on $[S, T]$ of bounded variation, vanishing at the point $S$. The total variation of a function $\mu(\cdot) \in \text{NBV}^+[S, T]$ is written $||\mu||_{TV}$. As is well known, each point $\mu(\cdot) \in \text{NBV}^+[S, T]$ defines a unique Borel measure on $[S, T]$. This associated measure is also denoted $\mu$. The space of continuous functions $x : [S, T] \to \mathbb{R}^n$ with supremum norm is written $C([S, T]; \mathbb{R}^n)$ and we denote by $C^*([S, T]; \mathbb{R}^n)$ its topological dual space.

Take a lower semicontinuous function $f : \mathbb{R}^k \to \mathbb{R} \cup \{+\infty\}$ and a point $\bar{x} \in \mathbb{R}^k$ such
that \( f(\bar{x}) < +\infty \). The subdifferential of \( f \) at \( \bar{x} \) is denoted \( \partial f(\bar{x}) \):

\[
\partial f(\bar{x}) := \{ \xi | \exists \xi_i \rightarrow \xi \text{ and } x_i \xrightarrow{\text{dom}f} \bar{x} \text{ such that } \\
\limsup_{x \rightarrow x_i} \frac{\xi_i \cdot (x-x_i) - \varphi(x) + \varphi(x_i)}{|x-x_i|} \leq 0 \text{ for all } i \in \mathbb{N} \},
\]

Here, the notation \( x_i \xrightarrow{\text{dom}f} \bar{x} \) is employed to indicate that all elements in the convergent sequence \( \{x_i\} \) lie in \( \text{dom} f \). For further information about subdifferentials, and related constructs in nonsmooth analysis, see [7], [12] and [13].

## 2 Multifunctions of Bounded Variation

Take a bounded interval \([S,T]\), a compact set \( A \subset \mathbb{R}^k \), a multifunction \( F(.,.,.) : [S,T] \times \mathbb{R}^n \times A \rightarrow \mathbb{R}^n \) and a continuous function \( \bar{x}(.) : [S,T] \rightarrow \mathbb{R}^n \). Generic elements in the domain of \( F(.,.,.) \) are denoted by \((t,x,a)\).

In this section we define a concept that makes precise the statement ‘\( F(t,x,a) \) has bounded variation with respect to the \( t \) variable, along \( \bar{x}(.) \), uniformly with respect to \( a \in A' \).’ If \( F(t,x,a) \) is independent of \((x,a)\) and single valued, i.e. \( F(t,x,a) = \{f(t)\} \) for some function \( f(.) : [S,T] \rightarrow \mathbb{R}^n \), this concept reduces to the standard notion ‘\( f(.) \) has bounded variation’.

For any \( t \in [S,T] \), \( \delta > 0 \) and partition \( \mathcal{T} = \{t_0 = S, t_1, \ldots, t_{N-1}, t_N = t\} \) of \([S,t]\), define \( I^\delta(\mathcal{T}) \in \mathbb{R}^+ \cup \{+\infty\} \) to be

\[
I^\delta(\mathcal{T}) := \sum_{i=0}^{N-1} \sup \{d_H(F(t_{i+1},x,a),F(t_i,x,a)) \mid x \in \bar{x}([t_i,t_{i+1}]) + \delta B, a \in A\}.
\]

Here, \( \bar{x}([t_i,t_{i+1}]) \) denotes the set \( \{\bar{x}(t) \mid t \in [t_i,t_{i+1}]\} \).

Take any \( \epsilon > 0 \). Let \( \eta^\delta(.) : [S,T] \rightarrow \mathbb{R}^+ \cup \{+\infty\} \) be the function defined as follows:

\[
\eta^\delta(t) = \sup \left\{ I^\delta(\mathcal{T}) \mid \mathcal{T} \text{ is a partition of } [S,t] \text{ s.t. diam}\{\mathcal{T}\} \leq \epsilon \right\}.
\]

in which

\[
\text{diam}\{\mathcal{T}\} := \sup\{t_{i+1} - t_i \mid i = 0, \ldots, N - 1\}.
\]

It is clear that, for any \( t \in [S,T] \), \( \delta > 0 \), \( \delta' > 0 \), \( \epsilon > 0 \), \( \epsilon' > 0 \),

\[
\delta' \leq \delta \text{ and } \epsilon' \leq \epsilon \implies 0 \leq \eta^\delta_{\epsilon'}(t) \leq \eta^\delta_\epsilon(t). \tag{2.1}
\]

(This relation is valid even when \( \eta^\delta_\epsilon(t) = +\infty \), according to the rule ‘\(+\infty \leq +\infty\’.)

We may therefore define the functions \( \eta^\delta(.) , \eta(.) : [S,T] \rightarrow \mathbb{R}^+ \cup \{+\infty\} \) to be

\[
\eta^\delta(t) := \lim_{\epsilon \downarrow 0} \eta^\delta_\epsilon(t) \text{ for } t \in [S,T] \tag{2.2}
\]

\[
\eta(t) := \lim_{\delta \downarrow 0} \eta^\delta(t) \text{ for } t \in [S,T]. \tag{2.3}
\]
Definition 2.1. Take a set \( A \subset \mathbb{R}^k \), a multifunction \( F(\cdot, \cdot) : [S, T] \times \mathbb{R}^n \times A \rightrightarrows \mathbb{R}^n \) and a function \( \bar{x}(\cdot) : [S, T] \rightarrow \mathbb{R}^n \). We say that \( t \rightarrow F(t, \cdot, \cdot) \) has bounded variation along \( \bar{x}(\cdot) \) uniformly over \( A \), if the function \( \eta(\cdot) \) given by Def. 2.1 satisfies \( \eta(T) < +\infty \).

If \( t \rightarrow F(t, \cdot, \cdot) \) has bounded variation along \( \bar{x}(\cdot) \) uniformly over \( A \), we refer to the function \( \eta(\cdot) \) as the cumulative variation function of \( t \rightarrow F(t, \cdot, \cdot) \) along \( \bar{x}(\cdot) \), uniformly over \( A \). We also refer to \( \eta^\delta(\cdot) \) and \( \eta^\epsilon(\cdot) \) as the \( (\delta, \epsilon) \)-perturbed cumulative variation function and \( \epsilon \)-perturbed cumulative variation function respectively.

If \( F(t, x, a) \) does not depend on \( a \), we omit mention of the qualifier ‘uniformly over \( A \)’. A function \( t \rightarrow L(t, \cdot, \cdot) \) is said to have bounded variation along \( \bar{x}(\cdot) \) uniformly over \( A \), if the associated multifunction \( t \rightarrow \{L(t, \cdot, \cdot)\} \) has this property.

Assume that \( t \rightarrow F(t, \cdot, \cdot) \) has bounded variation along \( \bar{x}(\cdot) \) uniformly over \( A \). Then there exist \( \delta > 0 \) and \( \epsilon > 0 \) for which \( \eta^\delta(T) < +\infty \). We list the following elementary properties of the accumulative variation functions (‘elementary’, in the sense that they are simple consequences of the definitions): for any \( \delta \in (0, \bar{\delta}] \) and \( \epsilon \in (0, \bar{\epsilon}] \),

\[
\begin{align*}
\text{(a): } & t \rightarrow \eta^\delta(t), \ t \rightarrow \eta^\epsilon(t) \text{ and } t \rightarrow \eta(t) \text{ are increasing, finite valued functions,} \\
\text{(b): } & \eta^\delta(t) \geq \eta^\epsilon(t) \geq \eta(t) \text{ for all } t \in [S, T] \\
\text{and} \\
\text{(c): } & \text{given any } [s, t] \subset [S, T] \text{ such that } t - s \leq \epsilon, \\
& d_H(F(t, y, a), F(s, y, a)) \leq \eta^\delta(t) - \eta^\delta(s), \quad (2.4)
\end{align*}
\]

for all \( y \in \bar{x}(t') + \delta \mathbb{B} \) for some \( t' \in [s, t] \) and \( a \in A \).

Example. An important potential role of the preceding constructs will be to derive regularity properties of value functions, minimizing arcs and other functions associated with an optimal control problem, in which the dynamic constraint is a differential inclusion \( \dot{x} \in F(t, x) \), when \( F(t, x) \) has bounded variation with respect to the \( t \) variable, ‘near’ a given state trajectory \( \bar{x}(\cdot) \). Regularity properties are typically related to the cumulative variation function \( \eta(\cdot) \) of \( t \rightarrow F(t, \cdot, \cdot) \). The more precise is the information about the cumulative variation the more informative is the corresponding regularity property that can be derived. This is the main reason why we have adopted the refined definition, Def. 2.1, for the formulation of the ‘bounded variation’ hypothesis, in place of a simpler one based on the condition (1.2), for some closed subset \( X \) that strictly contains the range of \( \bar{x}(\cdot) \) in its interior. The purpose of this example is to show that using the ‘refined’ definition can provide a more informative cumulative variation function.

Consider the function \( f : [0, 1] \times \mathbb{R} \rightarrow \mathbb{R} \) and the function \( \bar{x}(\cdot) : [0, 1] \rightarrow \mathbb{R} \):

\[
f(t, x) = t \times x \text{ and } \bar{x}(t) = t \text{ for } (t, x) \in [0, 1] \times \mathbb{R}.
\]
Take $X = \text{range}\{\bar{x}(.)\} = [0, 1]$. The cumulative variation function $\eta_{\text{simple}}(.)$ of $t \to f(t, .)$ related to condition (1.2) and defined by

$$\eta_{\text{simple}}(t) = \sup \left\{ \sum_{i=0}^{N-1} \sup_{x \in X} d_H(F(t_{i+1}, x), F(t_{i}, x)) \right\}$$

in which the outer supremum is taken over all possible partitions of $[0, t]$, is easily calculated to be:

$$\eta_{\text{simple}}(t) = t.$$

Also, the cumulative variation of $f(.)$ along $\bar{x}(.)$ following Def. 3.2, is

$$\eta(t) = \frac{1}{2} t^2.$$

Notice that for any (nontrivial) subinterval $[s, t] \subset [0, 1], t > s$,

$$\big(\eta_{\text{simple}}(t) - \eta_{\text{simple}}(s)\big) - (\eta(t) - \eta(s))\eta(t) = (t - s) - \frac{1}{2}(t^2 - s^2) = (t - s)(\frac{1}{2} - \frac{1}{2}(t + s)) (> 0),$$

from which it can be deduced that the Borel measure induced by $\eta(.)$ strictly minorizes that induced by $\eta_{\text{strict}}(.)$ in the sense

$$\int_D d\eta_{\text{simple}}(t) - \int_D d\eta(t) > 0$$

for any Borel subset $D \subset [0, 1]$ having nonempty interior. This demonstrates the greater precision that can be achieved in regularity analysis, using the ‘refined’ approach.

3 Continuity Properties

As is well known, an $\mathbb{R}^n$-valued function of bounded variation on a finite interval may be discontinuous, but it has everywhere left and right limits and it has at most a countable number points of discontinuity. A multifunction having bounded variation along a given continuous trajectory uniformly over a given set has similar properties, as described in the following proposition.

Proposition 3.1. Take a compact set $A \subset \mathbb{R}^k$, a continuous function $\bar{x}(.) : [S, T] \to \mathbb{R}^n$ and a multifunction $F(., ., .) : [S, T] \times \mathbb{R}^n \times A \to \mathbb{R}^n$ which has bounded variation along $\bar{x}(.)$ uniformly over $A$, and take some $\delta > 0$ such that $\eta^\delta(T) < +\infty$. Assume that

(C1) $F(., ., .)$ takes values closed, non-empty sets, $F(., x, a)$ is measurable for each $(x, a) \in \mathbb{R}^n \times A$ and there exists $c > 0$ such that

$F(t, x, a) \subset c\mathbb{B}$ for all $x \in \bar{x}(t) + \delta\mathbb{B}, t \in [S, T], a \in A.$ \hspace{1cm} (3.1)
(C2) There exists a modulus of continuity $\gamma(.) : \mathbb{R}^+ \to \mathbb{R}^+$ such that

$$F(t, x, a) \subset F(t, x', a') + \gamma(|x - x'| + |a - a'|)$$

for all $x, x' \in \bar{x}(t) + \delta \mathbb{B}$, $t \in [S, T]$ and $a, a' \in A$.

Take any $\delta \in (0, \bar{\delta})$. Then

(a): For any $\bar{s} \in [S, T]$ and $\bar{t} \in (S, T]$ , the one-sided limits

$$F(\bar{s}^+, x, a) := \lim_{\bar{s} \downarrow \bar{s}} F(s, x, a), \quad F(\bar{t}^-, y, a) := \lim_{\bar{t} \uparrow \bar{t}} F(t, y, a)$$

exist for every $x \in \bar{x}(\bar{s}) + \delta \mathbb{B}$, $y \in \bar{x}(\bar{t}) + \delta \mathbb{B}$ and $a \in A$.

(b): For any $\bar{s} \in [S, T]$ and $\bar{t} \in (S, T]$

$$\lim_{\bar{s} \downarrow \bar{s}} \sup_{x \in \bar{x}(\bar{s}) + \delta \mathbb{B}, a \in A} d_H(F(\bar{s}, x, a), F(s^+, x, a)) = 0$$

and

$$\lim_{\bar{t} \uparrow \bar{t}} \sup_{x \in \bar{x}(\bar{t}) + \delta \mathbb{B}, a \in A} d_H(F(\bar{t}, x, a), F(t^-, x, a)) = 0$$

(c): There exists a countable set $A$ such that, for every $t \in (S, T) \setminus A$ and $x \in \bar{x}(t) + \delta \mathbb{B}$,

$$\lim_{t' \to t} \sup_{x \in \bar{x}(t') + \delta \mathbb{B}, a \in A} d_H(F(t', x, a), F(t, x, a)) = 0.$$

Proof.

(a): We prove the first assertion. Proof of the second assertion is similar. Choose any $\bar{s} \in [S, T]$. Take $\epsilon > 0$ such that $\eta^\delta_T(\bar{s}) < +\infty$. Fix $\delta \in (0, \bar{\delta})$. Take any $x \in \bar{x}(\bar{s}) + \delta \mathbb{B}$, $a \in A$ and

$$v \in \limsup_{\bar{s} \downarrow \bar{s}} F(s, x, a).$$

By definition of ‘lim sup’, there exists $s_i \downarrow \bar{s}$ and $v_i \to v$ such that

$$v_i \in F(s_i, x, a) \text{ for all } i \text{ and } v_i \to v \text{ as } i \to \infty.$$

The assertion (a) will follow if we can show that, also,

$$v \in \liminf_{\bar{s} \downarrow \bar{s}} F(s, x, a),$$

i.e. the ‘lim sup’ and ‘lim inf’ coincide, in which case the limit exists. To show (3.3) we take an arbitrary sequence $t_j \downarrow \bar{s}$. Since $\bar{x}(\cdot)$ is continuous and $x \in \bar{x}(S) + \delta \mathbb{B}$, we can arrange, by eliminating elements in the sequence $\{(s_i, v_i)\}$, that, for every $j$, $\bar{s} \leq s_j < t_j$, $t_j - \bar{s} \leq \epsilon$ and $x \in \bar{x}(t_j) + \delta \mathbb{B}$ for all $t \in [\bar{s}, t_j]$, $j = 1, 2, \ldots$ But then, since $t_j - s_j \leq \epsilon$ and by property (2.1) of the $(\delta, \epsilon)$-perturbed cumulative variation function,

$$d_H(F(t_j, x, a), F(s_j, x, a)) \leq \eta^\delta_{t_j}(t_j) - \eta^\delta_{s_j}(s_j).$$
This means that, for each $j$, there exists $w_j \in F(t_j, x, a)$ and

$$|v_j - w_j| \leq \eta^\delta_\ell(t_j) - \eta^\delta_\ell(s_j).$$

We know however that, since $\eta^\delta_\ell(.)$ is a finite valued, monotone function, it has a right limit $\eta^\delta_\ell(s^+)$ at $s$. Hence

$$\lim_{j \to \infty} |v_j - w_j| \leq \lim_{j \to \infty} \left( \eta^\delta_\ell(t_j) - \eta^\delta_\ell(s_j) \right) \leq \eta^\delta_\ell(s^+) - \eta^\delta_\ell(s^+) = 0.$$

It follows that $v_j - w_j \to 0$. But then $v = \lim_j v_j = \lim_j w_j$. Since $t_j \downarrow \bar{s}$ was an arbitrary sequence, we conclude (3.3). We have confirmed (a).

(b) These assertions follow from (a), together with the compactness of the set $A$ and of the $\delta$ balls about $\bar{x}(\bar{s})$ and $\bar{x}(\bar{t})$, and with the assumed continuity properties of $(x, a) \to F(t, x, a)$.

(c) Let $A$ be the empty or countable subset of $(S, T)$ comprising points at which the finite-valued monotone function $\eta^\delta_\ell(.)$ is discontinuous. Fix a point $t \in (S, T) \setminus A$, $a \in A$ and $x \in \bar{x}(t) + \delta \mathbb{B}$. Take any $\rho > 0$. Since $\eta^\delta_\ell(.)$ is continuous at $t$, we may choose $\gamma > 0$ such that

$$\eta^\delta_\ell(t + \gamma) - \eta^\delta_\ell(t - \gamma) \leq \rho.$$

So, for any $t' \in [S, T]$ such that $|t' - t| \leq \rho \land \epsilon$,

$$\sup\{d_H(F(t', x, a), F(t, x, a)) : x \in \bar{x}(t) + \delta \mathbb{B}, a \in A\} \leq \eta^\delta_\ell(t' \lor t) - \eta^\delta_\ell(t' \land t) \leq \eta^\delta_\ell(t + \gamma) - \eta^\delta_\ell(t - \gamma) \leq \rho.$$

The continuity properties of $F(., x, a)$ at $t$ have been confirmed.

The following lemma provides information about how the cumulative variation function of a multifunction, and its $\delta$-perturbation, are affected by changes of $\delta$ and the parameter space for $a$.

**Lemma 3.2.** Take compact sets $A_1, A \subset \mathbb{R}^k$, a continuous function $\bar{x}(.)$ and a multifunction $F(., ., .) : [S, T] \times \mathbb{R}^n \times \mathbb{R}^k \rightarrow \mathbb{R}^n$. Assume hypotheses (C1) and (C2) of Prop. 3.1 are satisfied, and that $t \rightarrow F(t, ., .)$ has bounded variation along $\bar{x}(.)$ uniformly over $A$. Write $\eta_A(., .)$, $\eta_{A_1}(., .)$ for the cumulative variation functions of $t \rightarrow F(t, ., .)$ with respect to the sets $A$ and $A_1$ respectively, and $\eta^\delta_A(., .)$, $\eta^\delta_{A_1}(., .)$ for their $\delta$-perturbations. Let $\bar{\delta} > 0$ be such that $\eta^\delta_{A'}(T) < \infty$ for $A' = A_1$ and $A$. Then, for any $\delta', \delta \in (0, \bar{\delta})$ and $[s, t] \subset [S, T],$

$$A_1 \subset A \text{ and } \delta' \leq \delta \implies \eta_{A_1}(t) - \eta_{A_1}(s) \leq \eta^\delta_{A_1}(t) - \eta^\delta_{A_1}(s) \leq \eta^\delta_A(t) - \eta^\delta_A(s). \quad (3.4)$$

**Proof.** Assume $A_1 \subset A$ and take $0 < \delta' \leq \delta < \bar{\delta}$. It suffices to prove the inequality $\eta^\delta_{A_1}(t) - \eta^\delta_{A_1}(s) \leq \eta^\delta_A(t) - \eta^\delta_A(s)$, since the ‘left side’ inequality follows immediately by passing to the limit as $\delta' \downarrow 0$. Write $\eta^\delta_{A_\epsilon}$ for the $(\delta, \epsilon)$-perturbation of $\eta^{\delta}_A(., .)$, etc. Choose $\epsilon > 0$ such that $\eta^\delta_{A_\epsilon}(T) < \infty$. Take $[s, t] \subset [S, T]$. Then, by
Proposition 3.3. \[ \eta^\delta_{A,\epsilon}(t) \leq \eta^\delta_{A,\epsilon}(s) + 2 \times \gamma(c \times \epsilon) + G^\delta_\epsilon(s, t), \] where \( c \) and \( \gamma(\cdot) \) are as in hypotheses (C1) and (C2), and
\[
G^\delta_\epsilon(s, t) := \sup \left\{ \sum_{i=0}^{N} \sup_{x \in \bar{\mathcal{z}}([t_i,t_{i+1}]) + \delta B} d_H(F(t_{i+1}, x), F(t_i, x)) \right\},
\]
in which the supremum is taken over partitions \( \{t_i\} \) of \([s,t]\) of diameter at most \( \epsilon \).

From the definition of \( \eta \) and by \( \eta \),
\[
\eta^\delta_{A,\epsilon}(t) \geq \eta^\delta_{A,\epsilon}(s) + G^\delta_\epsilon(s, t).
\]
Passing to the limit as \( \epsilon \downarrow 0 \) in (3.5) and (3.6), and combining the resulting relations yields
\[
\eta^\delta_{A,\epsilon}(t) - \eta^\delta_{A,\epsilon}(s) \leq \eta^\delta_{A}(t) - \eta^\delta_{A}(s).
\]

The next proposition relates the cumulative variation function of the multifunction \( F(\cdot, x, a) \) to that of the derived multifunction \( \bar{F}(\cdot, x, a) \), obtained by replacing the end-point values by left and right limits.

**Proposition 3.3.** Take a compact set \( A \subset \mathbb{R}^k \), a continuous function \( \bar{x}(\cdot) : [S, T] \rightarrow \mathbb{R}^n \) and a multifunction \( F(\cdot, \cdot, \cdot) : [S, T] \times \mathbb{R}^n \times A \rightarrow \mathbb{R}^n \) which has bounded variation along \( \bar{x}(\cdot) \) uniformly over \( A \). Denote by \( \eta(\cdot) \) the cumulative variation function, and by \( \eta(\cdot) \) its \( \delta \)-perturbation. Assume that hypotheses (C1) and (C2) of Prop. 3.1 are satisfied for some \( \delta > 0 \). Let \( \bar{F}(\cdot, \cdot, \cdot) : [S, T] \times \mathbb{R}^n \times A \rightarrow \mathbb{R}^n \) be a multifunction such that, for \((t, x, a) \in [S, T] \times \mathbb{R}^n \times A,
\[
\bar{F}(t, x, a) = \begin{cases} F(S^+, x, a) & \text{if } t = S \text{ and } |x - \bar{x}(S)| < \delta \\
F(T^-, x, a) & \text{if } t = T \text{ and } |x - \bar{x}(T)| < \delta \\
F(t, x, a) & \text{otherwise}
\end{cases}
\]
(3.7)

(The limit sets \( F(S^+, x, a) \) and \( F(T^-, x, a) \) exist, by the preceding proposition.)

Then \( \bar{F}(\cdot, \cdot, \cdot) \) has bounded variation along \( \bar{x}(\cdot) \) uniformly over \( A \). Write \( \bar{\eta}(\cdot) \) and \( \bar{\eta}(\cdot) \) for its cumulative variation function and \( \delta \)-perturbation.

Take any \( \delta \in (0, \bar{\delta}) \). \( \bar{\eta}(\cdot) \) is right continuous at \( S \) and left continuous at \( T \), i.e.
\[
\bar{\eta}(S) = \lim_{s \downarrow S} \bar{\eta}(s) \quad \text{and} \quad \bar{\eta}(T) = \lim_{t \uparrow T} \bar{\eta}(t).
\]
(3.8)

Furthermore, the \( \delta \)-perturbed cumulative variation functions of \( F(\cdot, \cdot, \cdot) \) and \( \bar{F}(\cdot, \cdot, \cdot) \) are related as follows:
\[
\eta^\delta(t) = \begin{cases} \eta(t) - \sup_{x \in \bar{x}(S) + \delta B, a \in A} d_H(F(S, x, a), F(S^+, x, a)) & \text{for } t \in (S, T) \\
\eta^\delta(T) - \sup_{x \in \bar{x}(S) + \delta B, a \in A} d_H(F(S, x, a), F(S^+, x, a)) - \sup_{x \in \bar{x}(T) + \delta B, a \in A} d_H(F(T, x, a), F(T^-, x, a)) & \text{for } t = T.
\end{cases}
\]
(3.9)
Relation (3.9) implies, in particular, that
\[ \eta^\delta(t) - \eta^\delta(s) = \eta^\delta(t) - \eta^\delta(s) \] for any \([s, t] \subset (S, T)\). \hspace{1cm} (3.10)

The relations (3.8)-(3.10) remain valid when for \(\delta = 0\), under the interpretation \('\eta^0(.) = \eta(.)\) and \(\bar{\eta}^0(.) = \bar{\eta}(.)\)'.

**Proof of Prop. 3.3**
Take \(\bar{\epsilon} > 0\) such that \(\eta^\delta_\epsilon(T) < \infty\) and \(\delta \in (0, \bar{\delta})\). To begin, we verify the following assertion: for any \(\delta' \in (0, \delta)\)
\[ \eta^\delta(T) \leq \lim_{T' \to T} \eta^\delta(T') + \sup_{x \in \hat{\mathbb{E}}(T) + \delta \mathbb{B}, a \in A} d_H(F(T, x, a), F(T^-, x, a)), \] \hspace{1cm} (3.11)

We can choose \(T_1 \in (S, T)\) such that \(|T - T_1|\) is arbitrarily small and \(c \times |T - T_1| < \delta - \delta'\). For any \(T_2 \in (T_1, T]\) define
\[ G_\delta(T_1, T_2) := \sup \left\{ \sum_{i=0}^{N} \sup_{x \in \hat{\mathbb{E}}(T) + \delta \mathbb{B}, a \in A} d_H(F(t_{i+1}, x, a), F(t_i, x, a)) \right\}, \]
in which the ‘outer’ supremum is taken over all partitions \(\{t_i\}\) of \([T_1, T_2]\). Notice that the ‘inner’ suprema are all taken over the same set \((\hat{\mathbb{E}}(T) + \delta \mathbb{B}) \times A\). It follows that the value of \(G_\delta(T_1, T_2)\) is unchanged if we restrict the magnitude of the diameters of the \(t\) partitions considered in the definition; that is, for any \(\epsilon > 0\) we have
\[ G_\delta(T_1, T_2) = \sup \left\{ \sum_{i=0}^{N} \sup_{x \in \hat{\mathbb{E}}(T) + \delta \mathbb{B}, a \in A} d_H(F(t_{i+1}, x, a), F(t_i, x, a)) \mid \text{diam} \{t_i\} \leq \epsilon \right\}. \] \hspace{1cm} (3.12)

By considering the modification of arbitrary partitions of \([S, T]\) to include the extra ‘grid point’ \(T_1\), we can deduce that, for any \(\epsilon \in (0, \bar{\epsilon}]\),
\[ \eta^\delta_\epsilon(T) \leq \eta^\delta_\epsilon(T_1) + 2 \times \gamma(c \times \epsilon) + G_\delta(T_1, T). \]

Here, \(c\) and \(\gamma(.)\) are as in hypotheses (C1) and (C2). In the limit as \(\epsilon \downarrow 0\), we obtain
\[ \bar{\eta}^\delta(T) \leq \eta^\delta_\epsilon(T_1) + G_\delta(T_1, T). \] \hspace{1cm} (3.13)

For any \(\rho > 0\) there exists a partition \(\{t_0, \ldots, t_N\}\) of \([T_1, T]\) achieving the ‘outer’ supremum defining \(G_\delta(T_1, T)\), with error at most \(\rho\). It follows that
\[ G_\delta(T_1, T) \leq G_\delta(T_1, t_{N-1}) + \sup_{x \in \hat{\mathbb{E}}(T) + \delta \mathbb{B}} d_H(F(t_{N-1}, x), F(T^-, x)) + \rho. \] \hspace{1cm} (3.14)

But, in consequence of (3.12), we know that, for any \(\epsilon \in (0, \bar{\epsilon}]\),
\[ \eta^\delta_\epsilon(t_{N-1}) \geq \eta^\delta_\epsilon(T_1) + G_\delta(T_1, t_{N-1}). \]
In the limit, as \(\epsilon \downarrow 0\), we obtain
\[ \eta^\delta(t_{N-1}) \geq \eta^\delta_\epsilon(T_1) + G_\delta(T_1, t_{N-1}). \] \hspace{1cm} (3.15)
Since \( \eta^\delta(T_1) \leq \eta^\delta(T_1) \), it follows from (3.13), (3.14) and (3.15) that
\[
\eta^\delta(T) \leq \eta^\delta(t_{N-1}) + \sup_{x \in \tilde{x}} d_H(F(T_1, x, a), F(T, x, a)) + \rho.
\]
This relation is valid for \( T_1 \)’s arbitrarily close to \( T \) and any \( \rho > 0 \). Using Prop. 3.1 to evaluate the limit of the sup term on the right side, we deduce
\[
\eta^\delta(T) \leq \lim_{T' \to T} \eta^\delta(T') + \sup_{x \in \tilde{x}} d_H(F(T, x, a), F(T^-, x, a)).
\]
This confirms relation (3.11).

Our next task will be to relate the cumulative variation functions of \( t \to F(t, \ldots) \) and \( \tilde{t} \to F(t, \ldots) \) at times \( t < T \).

Fix \( t \in (S, T) \) and take \( \epsilon \in (0, \epsilon] \) such that \( \eta^\delta(T) < +\infty \). Let \( T = \{t_0 = S, \ldots, t_N = t\} \) be an arbitrary partition of \([S, t]\) with \( \dim\{T\} \leq \epsilon \). Take an arbitrary sequence \( s_j \downarrow S \). For \( j \) sufficiently large,
\[
\eta^\delta(t) \geq \sup \{d_H(F(s_j, x, a), F(S, x, a)) \mid x \in \tilde{x}(\mathbb{S}, s_j) + \delta B, a \in A\}
+ \sup \{d_H(F(s_j, x, a), F(t_1, x, a)) \mid x \in \tilde{x}(\mathbb{S}, t_1) + \delta B, a \in A\}
+ \sum_{i=1}^{N-1} \sup \{d_H(F(t_{i+1}, x, a), F(t_i, x, a)) \mid x \in \tilde{x}(\mathbb{S}, t_{i+1}) + \delta B, a \in A\}.
\]
In view of Prop. 3.1 we may pass to the limit as \( j \to \infty \) in this relation to obtain:
\[
\eta^\delta(t) \geq \sup \{d_H(F(S^+, x, a), F(S, x, a)) \mid x \in \tilde{x}(S) + \delta B, a \in A\}
+ \sup \{d_H(F(S^+, x, a), F(t_1, x, a)) \mid x \in \tilde{x}(\mathbb{S}, t_1) + \delta B, a \in A\}
+ \sum_{i=1}^{N-1} \sup \{d_H(F(t_{i+1}, x, a), F(t_i, x, a)) \mid x \in \tilde{x}(\mathbb{S}, t_{i+1}) + \delta B, a \in A\}.
\]
Since \( T \) was an arbitrary partition with \( \dim\{T\} \leq \epsilon \), it follows that
\[
\eta^\delta(t) \geq \sup \{d_H(F(S^+, x, a), F(S, x, a)) \mid x \in \tilde{x}(S) + \delta B, a \in A\} + \tilde{\eta}^\delta(t). \tag{3.16}
\]
Take again an arbitrary partition \( T = \{t_0 = S, \ldots, t_N = t\} \) of \([S, t]\). Then, for any \( \epsilon \in (0, \epsilon] \),
\[
\tilde{\eta}^\delta(t) \geq \sup \{d_H(F(S^+, x, a), F(t_1, x, a)) \mid x \in \tilde{x}(\mathbb{S}, t_1) + \delta B, a \in A\}
+ \sum_{i=1}^{N-1} \sup \{d_H(F(t_{i+1}, x, a), F(t_i, x, a)) \mid x \in \tilde{x}(\mathbb{S}, t_{i+1}) + \delta B, a \in A\}. \tag{3.17}
\]
By the triangle inequality we have, for each \( x \in \{\tilde{x}(t) + \delta B \mid t \in [S, t_1]\} \) and \( a \in A \),
\[
d_H(F(S^+, x, a), F(t_1, x, a)) \geq d_H(F(S, x, a), F(t_1, x, a)) - d_H(F(S^+, x, a), F(S, x, a)).
\]
Furthermore, 
\[ \max d_H(F(S^+, x, a), F(t_1, x, a)) \geq \max d_H(F(S, x, a), F(t_1, x, a)) - \max\{d_H(F(S^+, x, a), F(S, x, a)) , \]
where, in each term, the max is taken over \((x, a) \in \{\bar{x}(t) + \delta B \mid t \in [S, t_1]\} \times A\). Since \( T \) was an arbitrary partition such that \( \text{diam}\{T\} \leq \epsilon \), we deduce from (3.17) that 
\[ \eta_\epsilon^\delta(t) \geq \eta^\delta(t) - \max\{d_H(F(S^+, x, a), F(S, x, a)) \mid (x, a) \in \{\bar{x}(t) + \delta B \mid t \in [S, t_1]\} \times A\} . \]

This relation combines with (3.16) to yield 
\[ 0 \leq \eta^\delta(t) - \eta_\epsilon^\delta(t) - \max\{d_H(F(S^+, x, a), F(S, x, a)) \mid x \in \bar{x}(S) + \delta B, a \in A\} \leq \Delta(\epsilon, \delta) , \]
in which 
\[ \Delta(\epsilon, \delta) := \max\{d_H(F(S^+, x, a), F(S, x, a)) \mid x \in \{\bar{x}(t) + \delta B \mid t \in [S, (S + \epsilon) \wedge T]\} , a \in A\} - \max\{d_H(F(S^+, x, a), F(S, x, a)) \mid x \in \bar{x}(S) + \delta B, a \in A\} . \]  

Since \( \bar{x}(.) \) is continuous and, as is easily shown, \( F(S^+, \ldots) \) has modulus of continuity \( \gamma(.) \) on \( \{\bar{x}(S) + \delta B\} \times A \), where \( \gamma(.) \) is as in hypothesis (C2), we have 
\[ \lim_{\epsilon \downarrow 0} \Delta(\epsilon', \delta) = 0 . \]

Passing to the limit as \( \epsilon \downarrow 0 \) gives 
\[ \eta^\delta(t) = \bar{\eta}^\delta(t) + \max\{d_H(F(S^+, x, a), F(S, x, a)) \mid x \in \bar{x}(S) + \delta B, a \in A\} \] 
(3.19)

In the limit as \( \delta \downarrow 0 \) we obtain 
\[ \eta(t) = \bar{\eta}(t) + \sup_{a \in A} d_H(F(S^+, \bar{x}(S), a), F(S, \bar{x}(S), a)) \] 
(3.20)

We have validated the assertions in the proposition concerning cumulative variations of \( F \) and \( \bar{F} \) on the half open interval \([S, T)\).

Now we verify the right continuity of \( \bar{\eta}^\delta(.) \) and \( \bar{\eta}(.) \) at \( S \). We shall confirm the right continuity of only \( \bar{\eta}(.) \) at \( S \), in consequence of the relation 
\[ 0 \leq \eta(t) - \eta(S) = \eta(t) - 0 \leq \eta^\delta(t) - 0 = \eta^\delta(t) - \bar{\eta}^\delta(S) \quad \text{for all} \ t \in (S, T] . \]

Let us assume, in contradiction, that \( \bar{\eta}^\delta(.) \) is not right continuous at \( S \). Then there exists \( \alpha > 0 \) such that \( \bar{\eta}^\delta(t) - \bar{\eta}^\delta(S) = 0 \geq \alpha \) for all \( t \in [S, T] \). Choose any \( \epsilon > 0 \) such that \( \bar{\eta}^\delta(t) < \infty \). We can also arrange, by reducing the size of \( \epsilon \), that \( \Delta(\epsilon, \delta) \) given by (3.16) satisfies 
\[ \Delta(\epsilon, \delta) < \alpha/8 . \]

By Prop 3.1, we can find \( \bar{s} > 0 \) such that 
\[ \max_{x \in \bar{x}(S)^+ + \delta B, \ a \in A} d_H(F(\bar{s}, x, a), F(S^+, x, a)) \leq \alpha/4 . \]
By the properties of the supremum, we can choose a partition \( \{ s_0, \ldots, s_N \} \) of \([S, \bar{s}]\), of diameter at most \( \epsilon \), such that

\[
\tilde{\eta}_\delta(\bar{s}) \leq \max_{x \in \bar{x}([S, s_1]) + \delta B} d_H(F(s_1, x, a), F(S^+, x, a)) + \alpha/4 + \Sigma_2
\]

\[
= \Delta(\epsilon, \delta) + \max_{x \in \bar{x}(S) + \delta B} d_H(F(s, x, a), F(S^+, x, a)) + \alpha/4 + \Sigma_2 \quad (3.21)
\]

\[
\leq \alpha/8 + \alpha/4 + \Sigma_2 = \Sigma_2 + 5\alpha/8, \quad (3.22)
\]

in which \( \Delta(\epsilon, \delta) \) is as in (3.18) and

\[
\Sigma_2 := \sum_{i=1}^{N-1} \max_{x \in \bar{x}([s_i, s_{i+1}]) + \delta B} d_H(F(s_{i+1}, x, a), F(s_i, x, a)).
\]

But we can also choose a partition \( \{ t_0, \ldots, t_M \} \) of \([S, s_1] \) (which will have diameter not greater than \( \epsilon \)) such that

\[
\alpha \leq \tilde{\eta}_\delta(s_1) \leq \Sigma_1 + \alpha/4,
\]

where

\[
\Sigma_1 := \sum_{i=0}^{N-1} \max_{x \in \bar{x}([t_i, t_{i+1}]) + \delta B} d_H(F(t_{i+1}, x, a), F(t_i, x, a)).
\]

It follows that

\[
\Sigma_1 \geq 3\alpha/4.
\]

But since the concatenation of \( \{ t_0, \ldots, t_M \} \) and \( \{ s_1, \ldots, s_N \} \) is a partition of \([S, \bar{s}]\), of diameter no greater than \( \epsilon \), we know from the preceding inequality that

\[
\tilde{\eta}_\delta(\bar{s}) \geq \Sigma_1 + \Sigma_2 \geq \Sigma_2 + 3\alpha/4.
\]

But this contradicts (3.22). We have confirmed that \( \tilde{\eta}_\delta(\cdot) \) (and so also \( \eta(\cdot) \)) are continuous from the left at \( S \).

Next, we shall show that

\[
\eta^\delta(T) = \lim_{T' \to T} \eta^\delta(T') + \sup_{x \in \bar{x}(T) + \delta B, a \in A} d_H(F(T, x, a), F(T^-, x, a)), \quad (3.23)
\]

\[
\eta(T) = \lim_{T' \to T} \eta(T') + \sup_{a \in A} d_H(F(T, \bar{x}(T), a), F(T^-, \bar{x}(T), a)). \quad (3.24)
\]

This will complete the proof of the remaining assertions of the proposition. Indeed, since the multifunction \( t \to \bar{F}(t, \cdot, \cdot) \) is continuous at the right end-point \( T \), the analysis leading to (3.23), but applied to \( \bar{F} \), yields

\[
\bar{\eta}^\delta(T) = \lim_{T' \to T} \bar{\eta}^\delta(T') + 0 \quad \text{and} \quad \bar{\eta}(T) = \lim_{T' \to T} \bar{\eta}(T') + 0.
\]

This is the claimed right continuity of \( \bar{\eta}_\delta(\cdot) \) (and of \( \eta(\cdot) \)) at \( T \). On the other hand, (3.23) and (3.24) combine with (3.19) and (3.20) to yield the representation of \( \bar{\eta}_\delta(T) \)
in terms of \( \eta^\delta(T) \) in (3.24) (and the analogous representation of \( \tilde{\eta}(T) \)).

To prove (3.23) and (3.24) we first note that, since \( \delta' \rightarrow \tilde{\eta}^\delta(T) \) is monotone, we can find \( \delta_1 \in (\delta, \delta) \) such that \( \eta^\delta(T) \) is continuous at \( \delta_1 \). But then, by (3.11),

\[
\eta^\delta(T) \leq \lim_{T' \rightarrow T} \eta^\delta(T') + \sup_{x \in \bar{x}(T)+\delta_1 \mathbb{B}, a \in A} d_H(F(T,x,a),F(T',x,a)). \tag{3.25}
\]

By Lemma 3.2 however we have, for any \( T' \in (S,T) \),

\[
\tilde{\eta}^\delta(T) - \tilde{\eta}^\delta(T') \leq \tilde{\eta}^\delta_1(T) - \tilde{\eta}^\delta_1(T'). \tag{3.26}
\]

Consequently

\[
\eta^\delta(T) - \lim_{T' \rightarrow T} \eta^\delta(T') \leq \tilde{\eta}^\delta_1(T) - \lim_{T' \rightarrow T} \tilde{\eta}^\delta_1(T').
\]

This relation combines with (3.25) to give

\[
\eta^\delta(T) \leq \lim_{T' \rightarrow T} \eta^\delta(T') + \sup_{x \in \bar{x}(T)+\delta_1 \mathbb{B}, a \in A} d_H(F(T,x,a),F(T',x,a)). \tag{3.27}
\]

Since \( \delta_1 \) can be chosen such that \( \delta_1 - \delta \) is arbitrarily small and in view of the continuity properties of \( F(.,.,.) \), we see that the preceding relation is true when the supremum is taken over \( x \in \bar{x}(T) + \delta \mathbb{B} \) in place of \( x \in \bar{x}(T) + \delta_1 \mathbb{B} \).

For \( 0 < \epsilon' < \epsilon \) and \( 0 < \delta' < \delta \) sufficiently small, from the definition of \( \eta^\delta_1(.) \),

\[
\eta^\delta_1(T) \geq \eta^\delta_1(T - \epsilon') + \sup_{x \in \bar{x}([T-\epsilon,T]) + \delta \mathbb{B}, a \in A} d_H(F(T,x,a),F(T',x,a)).
\]

Passing to the limit, first as \( \epsilon' \downarrow 0 \), then as \( \delta' \downarrow 0 \) and then as \( \epsilon \rightarrow 0 \) and combining the resulting relation with (3.27) (when \( \delta_1 \) replaces \( \delta \) in the supremum operation) yields (3.28).

To prove (3.24) note that, passing to the limit in the preceding relation, first as \( \epsilon' \rightarrow 0 \), then as \( \delta' \rightarrow 0 \), then as \( \epsilon \rightarrow 0 \) and, finally, as \( \delta \rightarrow 0 \) and finally as \( \delta_1 \rightarrow 0 \), gives

\[
\eta(T) \geq \lim_{T' \rightarrow T} \eta(T') + \sup_{a \in A} d_H(F(T,\bar{x}(T),a),F(T',\bar{x}(T),a)). \tag{3.28}
\]

Also, passing to the limit as \( \delta \rightarrow 0 \) in (3.26), for fixed \( T' \), and then as \( T' \rightarrow T \) yields

\[
\eta(T) - \lim_{T' \rightarrow T} \eta(T') \leq \eta^\delta_1(T) - \lim_{T' \rightarrow T} \eta^\delta_1(T').
\]

But then from (3.25) we deduce

\[
\eta(T) \leq \lim_{T' \rightarrow T} \eta(T') + \sup_{x \in \bar{x}(T) + \delta_1 \mathbb{B}, a \in A} d_H(F(T,x,a),F(T',x,a)).
\]

Since this relation holds for \( \delta_1 \) arbitrarily small, it remains valid when we set \( \delta_1 = 0 \). Taking note also of (3.28), we conclude (3.24).
4 The Partial Variation Measure of a Function of a Scalar and a Vector Variable

In this section we examine in more detail the properties of a function \( m(., .) : [S, T] \times \mathbb{R}^n \rightarrow \mathbb{R}^r \) that has bounded variation with respect to the first variable, along a given trajectory \( x(\cdot) : [S, T] \rightarrow \mathbb{R}^n \). We restrict attention to a special case of the multifunctions earlier considered, in which the multifunction is point valued (i.e. \( m(., .) \) is a function), and no longer depends on a parameter \( a \).

The motivation arises from a desire to make sense of integrals arising in sensitivity analysis, of the form

\[
\int_S^T p^T(t) \frac{\partial m}{\partial t}(t, \bar{x}(t)) dt,
\]

in circumstances when \( m(t, x) \) has bounded variation with respect to the first variable, but fails to be continuously differentiable with respect to this variable. Here, \( p(\cdot) \) is a given continuous function. Notice that, if \( f(., .) \) is a continuously differentiable function, the integral can be written as

\[
\int_S^T p^T(t) d\mu(t),
\]

where \( \mu \) is the Borel (signed) measure on \([S, T]\) defined by \( d\mu = \alpha(t) dt \), in which \( \alpha(t) \) is the integrable function

\[
\alpha(t) = \frac{\partial m}{\partial t}(t, \bar{x}(t)).
\]

For \( m(t, x) \)'s that are merely of bounded variation with respect to \( t \), the idea is to define the integral according to (4.2), but now taking \( \mu \) to be some measure constructed from limits of finite difference approximations of the function \( m(., .) \).

We shall invoke the hypotheses:

(BV1): \( \bar{x}(\cdot) \) is continuous and \( x \rightarrow m(t, x) \) is continuously differentiable on the interior of \( \bar{x}(t) + \epsilon' \mathcal{B} \) for each \( t \in [S, T] \), for some \( \epsilon' > 0 \).

(BV2): (i): \( t \rightarrow m(t, \cdot) \) has bounded variation along \( \bar{x}(\cdot) \)

(ii): \( t \rightarrow \nabla_x m(t, \cdot) \) has bounded variation along \( \bar{x}(\cdot) \).

The first step is to define the measure \( \mu \) to replace \( \frac{\partial m}{\partial t}(t, \bar{x}(t)) \). The construction of the measure is based on the following lemma:

**Lemma 4.1.** Take functions \( m : [S, T] \times \mathbb{R}^n \rightarrow \mathbb{R}^r \) and \( \bar{x}(\cdot) : [S, T] \rightarrow \mathbb{R}^n \). Assume (BV1) and (BV2). Take any sequence of partitions \( \{t_j^i\}_{i=0}^N \), \( j = 1, 2, \ldots \) of \([S, T]\) such that \( \text{diam}\{t_j^i\} \rightarrow 0 \) as \( j \rightarrow \infty \) any any sequence \( \rho_j \downarrow 0 \). Take also any sequence of collections of \( n \)-vectors \( \{\xi_i^j\}_{i=0}^N \) such that

\[
\xi_i^j \in \bar{x}(t) + \rho^j \mathcal{B} \text{ for some } t \in [t_i^j, t_{i+1}^j]
\]

16
for each $i$ and $j$. Define the sequence of discrete measures $\mu^j$, $j = 1, 2, \ldots$ to be
\[
\mu^j = \sum_{i=0}^{N_i-1} \left[ m(t_{i+1}^j, \xi_i^j) - m(t_i^j, \xi_i^j) \right] \delta(t - t_i^j),
\]
in which $\delta(.)$ denotes the Dirac delta function.

Then there exists a (signed) Borel measure $\mu$ on $[S,T]$ such that
\[
\mu^j \rightarrow \mu \quad \text{with respect to the weak}^{*} \text{ topology on } C^*([S,T]; \mathbb{R}^{r}), \ i.e.
\]
\[
\int_{[S,T]} g^{T}(t) \, d\mu^j(t) \rightarrow \int_{[S,T]} g^{T}(t) \, d\mu(t) \quad \text{for every } g(.) \in C([S,T]; \mathbb{R}^{r}).
\]
Furthermore, the limit measure $\mu$ does not depend on the choice of sequences of partitions $\{t^j\}_{j=0}^{N_j}$, the sequence $\{\rho_j\}$ or the sequence of collections of vectors $\{\xi^j\}_{j=0}^{N_j}$ satisfying the stated conditions.

**Proof.** Let $\eta^j(\cdot)$ and $\tilde{\eta}^j(\cdot)$ denote the $(\delta, \epsilon)$ perturbed cumulative variation functions of $t \rightarrow m(t, \cdot)$ and $t \rightarrow \nabla_x m(t, \cdot)$, respectively along $\bar{x}(\cdot)$. We can choose $\epsilon > 0$ and $\delta > 0$ such that $\eta^j(T) < \infty$, $\tilde{\eta}^j(T) < \infty$ and $\theta_{\bar{x}}(\epsilon) \leq \delta$, where $\theta_{\bar{x}}(\cdot)$ is a continuity modulus for $\bar{x}(\cdot)$.

Take any sequence of partitions $\{t^j_i\}$ of $[S,T]$, $j = 1, 2, \ldots$, any sequence or real numbers $\rho^j \downarrow 0$ and any sequence $\{\xi^j_i\}$, $j = 1, 2, \ldots$ of collections of $n$-vectors with the properties in the lemma statement. Write
\[
\epsilon_j := \sup_{j' \geq j} \text{diam } \{t^j_i\}
\]
By assumption $\epsilon_j \downarrow 0$, as $j \rightarrow \infty$. Fix $j$ and $j' (> j)$. Consider the case
\[(T): \{t^j_i\} \subset \{t^j_i\}, \ i.e. \ \{t^j_i\} \ \text{is a sub-partition of } \{t^j_i\}.
\]
We relabel the sequence $\{t^j_i\}$ as $\{s_0 \ldots s_M\}$. Then, since $\{t^j_i\}$ is a sub-partition of $\{t^j_i\}$, $\{\xi^j_i\}$ can be written
\[
\{s_{0\ell}\}_{\ell=0}^{\ell_0} \cup \{s_{(M-1)\ell}\}_{\ell=0}^{\ell_{M-1}}
\]
in which $s_{0\ell} = s_0$ and $s_{i\ell} = s_{i+1}$ for $i = 1, \ldots, M - 1$. Relabel the $n$-vectors associated with these partitions $\xi_0, \ldots, \xi_{M-1}$ and $\xi_{i\ell}$, $\ell = 0, \ell_i - 1, i = 1, \ldots, M - 1$. Take any continuous function $g(.) : [S,T] \rightarrow \mathbb{R}^r$. Then
\[
\langle \mu^j - \mu^j', g(.) \rangle := \int_{[S,T]} g(t)(d\mu^j(t) - d\mu^j'(t)) = \sum_{i=0}^{M-1} \left[ g^T(s_i) (m(s_{i+1}, \xi_i) - m(s_i, \xi_i))
\right.
\]
\[
\left. - \sum_{\ell=0}^{\ell_i-1} g^T(s_{i\ell}) (m(s_{\ell+i+1}, \xi_{i\ell}) - m(s_{i\ell}, \xi_{i\ell})) \right].
\]
Using the fact that
\[ |m(s_{i(t+1)}, \xi_{it}) - m(s_{it}, \xi_{it})| \leq \eta^\delta(s_{i(t+1)}) - \eta^\delta(s_{it}), \] etc.,
we can write
\[ \langle \mu^j - \mu'^j, g(.\rangle = a + e_1, \quad (4.3) \]
where
\[ a = \sum_{i=0}^{M-1} g^T(s_i) \left[ (m(s_{i+1}, \xi_i) - m(s_i, \xi_i)) \right. \]
\[ \left. - \sum_{t=0}^{\ell_i-1} (m(s_{i(t+1)}, \xi_{it}) - m(s_{it}, \xi_{it})) \right]. \quad (4.4) \]
and \( e_1 \) is an ‘error term’ that satisfies
\[ |e_1| \leq \theta_g(\epsilon_j) \times \sum_{i,l} \left( \eta^\delta(s_{i(t+1)}) - \eta^\delta(s_{it}) \right) = \theta_g(\epsilon_j) \times ||\eta^\delta(.)||_{TV}. \]
Here, \( \theta_g(.) \) is a continuity modulus for \( g(.) \).

Using the exact first order Taylor expansion formula, we can write terms in the inner summation on the right of (4.3) as
\[ g^T(s_i) (m(s_{i(t+1)}, \xi_{it}) - m(s_{it}, \xi_{it})) \]
\[ = g^T(s_i) (m(s_{i(t+1)}, \xi_i) - m(s_{it}, \xi_i)) \]
\[ + g^T(s_i) \left( \nabla_x m(s_{i(t+1)}, \hat{\xi}_{it}) - \nabla_x m(s_{it}, \hat{\xi}_{it}) \right) \cdot (\xi_{it} - \xi_i) \]
for \( n \)-vectors \( \hat{\xi}_{it} \) satisfying \( |\hat{\xi}_{it} - \bar{x}(s_{it})| \leq 3 \times (\theta_x(\epsilon_j) + \rho_j) \leq \bar{\delta}, \) for \( l = 0, \ldots, l_{i-1}, \)
all values of the indices \( i, \) and all \( j \) sufficiently large. We note also that
\[ |\xi_{it} - \xi_i| \leq 2 \times (\theta_x(\epsilon_j) + \rho_j). \]
Substituting these relations into (4.4), noting cancellation of terms and, finally, using the fact that \( t \to \nabla_x m(t,.) \) has bounded variation, we arrive at
\[ a = 0 + \ldots + 0 + e_2, \]
where \( e_2 \) is an error term that satisfies \( |e_2| \leq 2 \times (\theta_x(\epsilon_j) + \rho^j) \times ||g(.)||_C \times ||\eta^\delta(.)||_{TV}. \)

It now follows from (4.3) and (4.4) that
\[ \langle \mu^j - \mu'^j, g(.) \rangle \leq \theta_g(\epsilon_j) \times ||\eta^\delta(.)||_{TV} + 2 \times (\theta_x(\epsilon_j) + \rho_j) \times ||g(.)||_C \times ||\eta^\delta(.)||_{TV}. \quad (4.5) \]
Recall that (1.5) has been proved in the case (T). Suppose that (T) is not satisfied, i.e. \( \{l^j_i\} \) is not a sub-partition of \( \{l^j_i\} \). We shall show that a similar estimate is valid. The key observation here is that, given the two partitions, we can construct a
new partition \( \{ \tilde{t}_i \} \) of \([S, T]\), simply by combining all the discretization times of the two partitions. Write \( \tilde{\mu} \) for the measure
\[
\tilde{\mu} = \sum_i \left[ m(\tilde{t}_{i+1}, \bar{x}(\tilde{t}_i)) - m(\tilde{t}_i, \bar{x}(\tilde{t}_i)) \right] \delta(t - \tilde{t}_i) .
\]

Applying the preceding analysis, first to \( \mu^j \) and \( \tilde{\mu} \) and then to \( \mu^{j'} \) and \( \tilde{\mu} \), and noting the triangle inequality, we arrive at:
\[
\langle \mu^j - \mu^{j'}, g(.) \rangle \leq \langle \mu^j - \tilde{\mu}, g(.) \rangle + \langle \mu^{j'} - \tilde{\mu}, g(.) \rangle \\
\leq 2 \times \left( \theta g(e_j) \times ||\eta^j_k(\cdot)||_{TV} + (\theta g(e_j) + \rho_j) \times ||g(.)||_{C} \times ||\eta^j_k||_{TV} \right) .
\]

This relation implies
\[
\lim_{j \to \infty} \sup_{j' \geq j} \langle \mu^j - \mu^{j'}, g(.) \rangle = 0 .
\]

We have shown that, for arbitrary continuous \( g(.) \), \( \{ \langle \mu^j, g(.) \rangle \} \) is a Cauchy sequence in \( \mathbb{R} \). the sequence therefore has a limit.

In consequence of property \( [2.3] \) of functions having bounded variation, the measures \( \{ \mu^j \} \) are bounded by \( \eta^j_k(T) \), for \( j \) sufficiently. Since closed balls in the \( C^*([S, T], \mathbb{R}^r) \) are weak* compact there exists a Borel measure \( \mu \) on \([S, T]\) and a subsequence \( \{ \mu^{j_k} \} \) of \( \{ \mu^j \} \) such that
\[
\mu^{j_k} \to \mu \quad \text{with respect to the weak* topology},
\]
as \( k \to \infty \). But then, by the preceding analysis,
\[
\lim_{j \to \infty} \langle \mu^j, g(.) \rangle = \lim_{k \to \infty} \langle \mu^{j_k}, g(.) \rangle = \langle \mu, g(.) \rangle ,
\]
for any \( g(.) \in C([S, T]; \mathbb{R}^r) \). We have demonstrated that there exists a Borel measure \( \mu \) such that \( \mu^j \) converges to \( \mu \) in the manner claimed (weak* convergence in the dual space).

We now prove the final assertion of the lemma (‘uniqueness of the limit’). If it were not true, there would exist two sequences of Borel measures \( \{ \mu^j \} \) and \( \{ \tilde{\mu}^j \} \) on \([S, T]\) that converge to different limits \( \mu \) and \( \tilde{\mu} \) (respectively), with respect to the weak* topology. The fact that the limits are distinct means that there exist some \( g^*(\cdot) \in C([S, T]; \mathbb{R}^r) \) such that
\[
\langle \mu, g^*(\cdot) \rangle \neq \langle \tilde{\mu}, g^*(\cdot) \rangle . \tag{4.6}
\]

Now construct a new sequence \( \tilde{\mu} \) by alternating elements in the two sequences. By the preceding analysis, there exists a Borel measure \( \tilde{\mu} \) such that \( \tilde{\mu}^j \to \tilde{\mu} \) in the weak* topology, as \( j \to \infty \). So
\[
\lim_{j \to \infty} \langle \tilde{\mu}^j, g^*(\cdot) \rangle = \langle \tilde{\mu}, g^*(\cdot) \rangle .
\]

But the sequence \( \{ \langle \tilde{\mu}^j, g^*(\cdot) \rangle \} \) cannot converge, because there exist two subsequences, one with limit \( \langle \mu, g^*(\cdot) \rangle \) and the other with limit \( \langle \tilde{\mu}, g^*(\cdot) \rangle \), which are distinct by \( [4.6] \). This contradiction completes the proof.
Definition 4.2. Take functions \( m(., .) : [S, T] \times \mathbb{R}^n \to \mathbb{R}^r \) and \( \bar{x}(.) \). Assume hypothesis (BV1) and (BV2) are satisfied. Then the partial variation measure of \( t \to m(t, .) \) along \( \bar{x}(.) \), written

\[
B \to \int_B d_t m(t, \bar{x}(t))
\]

is the Borel measure on \([S, T]\):

\[
\mu = \lim_j \mu^j,
\]

in which the limit is taken in the weak* topology of \( C([S, T]; \mathbb{R}^r) \). Here, \( \{\mu^j\} \) is any sequence of discrete Borel measures, each of the form

\[
\mu^j = \sum_{i=0}^{N_j-1} \left[ m(t^j_{i+1}, \xi^j_i) - m(t^j_i, \xi^j_i) \right] \delta(t - t^j_i),
\]

in which \( \{t^j_i\}_{i=1}^{N_j} \) is a partition of \([S, T]\), \( \{\xi^j\}_{i=0}^{N_j-1} \) is a collection of \( n \)-vectors such that \( \xi^j_i = \bar{x}(t) \) for some \( t \in (t^j_{i+1}, t^j_i) \), and \( \text{diam}\{\{t^j_i\}\} \to 0 \) as \( j \to \infty \).

(The definition of \( B \to \int_B d_t m(t, \bar{x}(t)) \) unambiguous since, according to the preceding analysis, the limiting measure \( \mu \) is the same for all choices of sequences \( \{\mu^j\} \).)

The following proposition relates the value that the partial variation measure takes on a subinterval \([a, b] \subset [S, T]\) and the difference in values of \( m(., x) \) at \( a \) and \( b \), for fixed \( x \).

Proposition 4.3. Take functions \( m(., .) : [S, T] \times \mathbb{R}^n \to \mathbb{R}^r \) and \( \bar{x}(.) \). Assume hypothesis (BV1) and (BV2) are satisfied. Denote by \( \eta(.) \) and \( \bar{\eta}(.) \) the cummulative variation functions of \( t \to m(., .) \) and \( t \to \nabla_x m(., .) \), respectively. (We write the \( \eta^\delta(.) \), \( \eta^\delta(.) \), etc., for their perturbed versions.)

Take \( \delta > 0 \) such that \( \eta^\delta(T) < +\infty \) and \( \bar{\eta}^\delta(T) < +\infty \) and \( \xi \in \mathbb{R}^n \) such that \( \xi = \bar{x}(t) \) for some \( t \in [a, b] \). Assume that

\[
\theta_{\bar{x}}(|b - a|) \leq \delta,
\]

where \( \theta_{\bar{x}}(.) \) is a continuity modulus for \( \bar{x}(.) \). Then

\[
\left| \int_{[a,b]} d_t m(t, \bar{x}(t)) - (m(b, \xi) - m(a, \xi)) \right| \leq \\
\theta_{\bar{x}}(|b - a|) \left( \bar{\eta}^\delta(b) - \bar{\eta}^\delta(a) \right) + \left( \eta(a) - \lim_{a' \to a} \eta(a') \right) + \left( \lim_{b' \downarrow b} \eta(b') - \eta(b) \right).
\]

(The second term on the right is interpreted as 0 if \( a = S \), and the third as 0 if \( b = T \).)

**Proof.** Fix \([a, b] \subset [S, T]\) and \( \delta > 0 \) such that \( \eta^\delta(T) < \infty \) and \( \bar{\eta}^\delta(T) < \infty \) and (4.7) is satisfied. We shall assume \( S < a < b < T \). The remaining cases when \( a \) or \( b \)
coincide with an endpoint of \([S, T]\) are treated similarly.

Let \(\{G_k(.) : [S, T] \to \mathbb{R}^{r \times r}\} \) be a sequence continuous functions such that
\[
G_k(t) = I_{r \times r} \text{ for } t \in [a, b] \\
|G_k(t)| = 0 \text{ if } t \leq a - 1/k \text{ or } b + 1/k \leq t \\
|G_k(t)| \leq 1 \text{ if } a - 1/k \leq t \leq a \text{ or } b \leq t \leq b + 1/k.
\]

Take any index value \(k\) and \(\epsilon > 0\) sufficiently small that \(\eta^k(T) < \infty\) and \(\tilde{\eta}^k(T) < \infty\).

Let \(\{t^j_i\}_{i=0}^{N_j} \) be a sequence of partitions of \([S, T]\) such that \(\text{diam}\{t^j_i\} \to 0\) as \(j \to 0\) and such that \(\{t^j_i\}\) contains \(a\) and \(b\) for each \(j\). Now define
\[
\mu^j = \sum_{i=0}^{N_j-1} \left[ m(t^j_{i+1}, \bar{x}(t^j_i)) - m(t^j_i, \bar{x}(t^j_i)) \right] \delta(t - t^j_i).
\]

By Lemma 4.1 applied component-wise,
\[
\int_{[S, T]} G_k(t) \, d\mu^j(t) \to \int_{[S, T]} G_k(t) \, d \mu^j(t) \text{ as } j \to \infty.
\]

For each \(j\), let \(i = m^1_j\) and \(j = m^2_j\) be the index values such that \(t_{m^1_j}^j = a\) and \(t_{m^2_j}^j = b\). Then, for each \(j\),
\[
\int_{[S, T]} G_k(t) \, d\mu^j(t) - (m(b, \xi) - m(a, \xi)) = \Sigma_1 + \Sigma_2 + \Sigma_3,
\]
in which
\[
\Sigma_1 = \sum_{i=0}^{m^1_j-1} G_k(t_i) \left[ m(t^j_{i+1}, \bar{x}(t^j_i)) - m(t^j_i, \bar{x}(t^j_i)) \right]
\]
\[
\Sigma_2 = \sum_{i=m^1_j}^{m^2_j-1} \left[ m(t^j_{i+1}, \bar{x}(t^j_i)) - m(t^j_i, \bar{x}(t^j_i)) \right] - [m(b, \xi) - m(a, \xi)]
\]
\[
\Sigma_3 = \sum_{i=m^2_j}^{N_j-1} G_k(t_i) \left[ m(t^j_{i+1}, \bar{x}(t^j_i)) - m(t^j_i, \bar{x}(t^j_i)) \right]
\]

Consider the term \(\Sigma_2\). Take any \(\nu \in \mathbb{R}^n\). Then, by the exact first order Taylor
expansion formula, we have for \( j \) sufficiently large,
\[
\nu^T \sum_{i=m_i^j}^{m_i^{j-1}} \left[ m(t_{i+1}^j, \bar{x}(t_i^j)) - m(t_i^j, \bar{x}(t_i^j)) \right]
\]
\[
= \nu^T \left( \sum_{i=m_i^j}^{m_i^{j-1}} \left[ m(t_{i+1}^j, \xi) - m(t_i^j, \xi) \right] + \left[ \nabla_x m(t_{i+1}^j, \xi^{\nu_i^j}) - \nabla_x m(t_i^j, \xi^{\nu_i^j}) \right] \cdot \left( \bar{x}(t_i^j) - \xi \right) \right)
\]
\[
= \nu^T \left( [m(b, \xi) + 0 \ldots 0 - m(a, \xi)]
+ \theta_b(|b - a|) \times \sum_{i=m_i^j}^{m_i^{j-1}} \left[ \nabla_x m(t_{i+1}^j, \xi^{\nu_i^j}) - \nabla_x m(t_i^j, \xi^{\nu_i^j}) \right] \right),
\]
in which \( \xi^{\nu_i^j} \in \bar{x}(a) + \delta \mathbb{B} \), for each \( i \) and all \( j \) sufficiently large. (We have used the fact that \( G_k(t) = I_{r \times r}(t) \) for \( t \in [a, b] \).) But \( t \to \nabla_x m(t,.) \) has bounded variation, so we can conclude that, for \( j \) sufficiently large,
\[
|\nu^T \Sigma_2| \leq |\nu| \left( \bar{\eta}_e^\delta(b) - \bar{\eta}_e^\delta(a) \right) \times (\theta_b(|b - a|))
\]
Since \( \nu \) is an arbitrary \( r \)-vector,
\[
|\Sigma_2| \leq \left( \bar{\eta}_e^\delta(b) - \bar{\eta}_e^\delta(a) \right) \times (\theta_b(|b - a|)). \quad (4.10)
\]
Now take any \( \delta' \in (0, \delta) \). Since \( G_k(.) \) satisfies \( |G_k(.)| \leq 1 \) on \([S, T]\setminus[a, b]\) and vanishes on \([S, T]\setminus(S - 1/k, T + 1/k]\), we deduce from property 3.2 of cumulative variation functions that, for sufficiently large \( j \),
\[
|\Sigma_1| \leq \eta_e^\delta(a) - \eta_e^\delta(S \vee (a - 1/k)) \quad \text{and} \quad |\Sigma_3| \leq \eta_e^\delta(S \vee (b + 1/k)) - \eta_e^\delta(b). \quad (4.11)
\]
Noting (4.8), (4.9), (4.10) and (4.11) and passing to the limit as \( j \to \infty \) gives
\[
|\int_{[S, T]} G_k(t) d\mu(t) - (m(b, \xi) - m(a, \xi))| \leq \bar{\eta}_e^\delta(b) - \bar{\eta}_e^\delta(a)
+ (\eta_e^\delta(a) - \eta_e^\delta(S \vee (a - 1/k)) + (\eta_e^\delta(S \vee (b + 1/k)) - \eta_e^\delta(b)) \quad (4.12)
\]
But \( \delta' > 0 \) and \( \epsilon > 0 \) are arbitrary, sufficiently small numbers. We may therefore pass to the limit as first \( \epsilon \downarrow 0 \) and second as \( \delta' \downarrow 0 \), to deduce the validity of the preceding relation when \( \eta_e^\delta(.) \) and \( \eta_e^{\delta'}(.) \) are replaced by \( \eta^\delta(.) \) and \( \eta^{\delta'}(.) \), respectively.

So far \( k \) has been fixed. Finally, we pass to the limit as \( k \to \infty \). Since \( G_k(t) \to I_{r \times r} \times \chi_{[a, b]} \) everywhere and the monotone function \( \eta(.) \) has everywhere one-sided limits, we deduce with the help of the Dominated Convergence Theorem that
\[
|\int_{[a, b]} d\mu(t, \bar{x}(t)) - (m(b, \xi) - m(a, \xi))| \leq
\left( \bar{\eta}_e^\delta(b) - \bar{\eta}_e^\delta(a) \right) + \left( \eta(a) - \lim_{a \uparrow a'} \eta(a') \right) + \left( \lim_{a \downarrow b} \eta(b) - \eta(b) \right).
\]
The proof is complete.
5 An Application

Consider a control system relating the control function \( u(\cdot) \) to an output function \( y(t) \) according to

\[
(S) \quad \begin{cases} 
\dot{x}(t) = f(x(t), u(t)) & \text{a.e } t \in [S, T] \\
u(t) \in \Omega \\
y(t) = g(x(t)) & \text{for } t \in [S, T], \\
x(0) = x_0
\end{cases}
\]

the data for which comprises: functions \( f(\cdot, \cdot) : \mathbb{R}^n \times \mathbb{R}^m \to \mathbb{R}^n \) and \( g : \mathbb{R}^n \to \mathbb{R} \), a set \( \Omega \subset \mathbb{R}^m \) and an \( n \)-vector \( x_0 \).

Let \( \bar{u}(\cdot) \) be a control function that has been chosen to give a desired value to the output at time \( T \), which we write

\[
J(u(\cdot)) := g(x(T; u(\cdot), x_0))
\]  

where \( x(T; u(\cdot), x_0) \) denotes the solution to the differential equation in the control system description, for a given control function and initial condition. (Hypotheses will be imposed ensuring the existence and uniqueness solutions.) Write

\[
\bar{x}(t) = x(T; \bar{u}(\cdot), x_0).
\]

In this section we focus attention on this phenomenon: in control engineering it is often the case that a feedback control cannot be implemented perfectly, but only with a time delay. This is perhaps most notably the case in process control, where controlled chemical reactors are routinely modelled with a pure delay at the input, to take account of the finite rate of flow of fluids in the reactor, etc. (See, for example, the widely studied the Tennessee Eastman challenge controller design problem, in which the system equations take the form of a matrix of first order lags with pure time delay \([9]\). The presence of a time delay complicates the controller design as so, if it is small, it is often ignored. To justify the use of idealized ‘delay-free’ models, it then becomes necessary to carry out a sensitivity analysis, to quantify the errors in the output \( J(u(\cdot)) \) when small delays are introduced to the controller implementation. We need then to look at consequences of applying the control

\[
u^h(t) := \begin{cases} 
\bar{u}(S) & \text{if } t + h < S \\
\bar{u}(t - h) & \text{if } S \leq t + h \leq T \\
\bar{u}(T) & \text{if } T < t + h.
\end{cases}
\]  

Notice we allow \( h \) to be both positive (a delay) or negative (an advance). The effect of introducing the delay on the output at output at time \( T \) is quantified by

\[
J(u^h(\cdot)) := g(x(T; u^h, x_0)).
\]

Suppose that \( f(\cdot, \cdot) \) is continuosly differentiable and globally Lipschitz continuous. If the control \( \bar{u}(\cdot) \) is an absolutely continuous function, a routine analysis yields the information that \( h \to J(u^h(\cdot)) \) is differentiable at the origin with gradient

\[
\frac{d}{dh} J(u^h(\cdot))|_{h=0} = \int_{[S,T]} p^T(t) \nabla_u f(\bar{x}(t), \bar{u}(t)) \frac{du}{dt}(t) dt,
\]  

\( 23 \)
in which \( p(.) : [S, T] \rightarrow \mathbb{R}^n \) is the solution to the costate equation:
\[
\begin{cases}
-\dot{p}(t) = \nabla_x f^T(\bar{x}(t), \bar{u}(t))p(t) \\
p(T) = \nabla_x g^T(\bar{x}(T)) .
\end{cases}
\] (5.4)

It is sometimes required to consider controls \( \bar{u}(.) \) that are not absolutely continuous (‘bang-bang’ controls arising from the solution to minimum time problems, for example). Is it possible to establish regularity properties of \( h \rightarrow J(u^h(.) ) \) and to derive a formula akin to (5.3) for a larger class of controls \( \bar{u}(.) \)? The following proposition provides a positive answer, when \( \bar{u}(t) \) is a function of bounded variation.

**Proposition 5.1.** Consider the control system \((S)\) and a control function \( \bar{u}(.) \). Assume that, for some constants \( K > 0, c > 0, k_1 > 0 \) and \( \delta > 0 \), and some function \( \theta(.) : (0, \infty) \rightarrow (0, \infty) \) such that \( \lim_{s \downarrow 0} \theta(s) = 0 \):

**(C1):** \( g(.) \) is a \( C^1 \) function,

**(C2):** \( f(., u) \) is a \( C^1 \) function for each \( u \in \Omega \) and
\[
(i): |f(x, u)| \leq c[1 + |x|] \text{ for all } x \in \mathbb{R}^n, u \in \Omega
\]
\[
(ii): |\nabla_x f(x, u)| \leq K \text{ for all } x \in \mathbb{R}^n \text{ and } u \in \Omega,
\]
\[
(iii): |f(x, u) - f(x', u) - \nabla_x f(x', u)| \leq \theta(|x - x'|) \times |x - x'|
\]
for all \( x, x' \in \bar{x}(t) + \delta B \) and \( u \in \Omega \).

**(C3):** There exists \( k_1 > 0 \) and \( \delta > 0 \) such that
\[
|f(x, u) - f(x, u')| + |\nabla_x f(x, u) - \nabla_x f(x, u')| \leq k_1|u - u'|
\]
for all \( x \in \bar{x}(t) + \delta B, u, u' \in \Omega \) and \( t \in [S, T] \).

Assume also that

**(BV):** \( \bar{u}(.) \) has bounded variation.

For any number \( h \in R \) define \( u^h(.) : [S, T] \rightarrow \mathbb{R}^m \) according to (5.2). Write \( x^h(.) \) for the solution on \([S, T]\) of \( \dot{x}(t) = f(x(t), u^h(t)), x(S) = x_0 \), which, for sufficiently small \( h \), exists and is unique, in consequence of hypothesis (C2). Write
\[
m^h(t, x) := f(x, u^h(t)) .
\] (5.5)

Then, for all \( h \) in some neighborhood of 0:

(a): \( t \rightarrow m^h(t, .) \) and \( t \rightarrow \nabla_x m^h(t, .) \) have bounded variation along \( \bar{x}(.) \),

(b): \( h' \rightarrow J(u^{h'}(.) ) \) (given by (5.1)) has one sided derivatives (from left and right) at \( h' = h \):
\[
\lim_{h' \downarrow h} \frac{J(u^{h'}(.) ) - J(u^h(.) )}{h' - h} = -\int_{[S, T]} p_h^T (t) d_t m^h(t, \bar{x}(t))
\] (5.6)
and
\[
\lim_{h' \uparrow h} \frac{J(u^{h'}(.) ) - J(u^h(.) )}{h - h'} = -\int_{[S, T]} p_h^T (t) d_t m^h(t, \bar{x}(t)) .
\] (5.7)

(In these relations, \( p_h(.) \) is the solution to (5.4) when \( u^h(.) \) and \( x^h(.) \) replace \( \bar{u}(.) \) and \( \bar{x}(.) \), and \( B \rightarrow \int_B d_t m^h(t, \bar{x}(t)) \) is the partial variation measure associated with \( m^h(., .) \).)
(c): If \( \bar{u}(.) \) is continuous at both endpoints \( S \) and \( T \), the mapping \( h' \to J(u^{h'}(.)) \) is differentiable at \( h \) and its derivative is
\[
\lim_{h' \to h} \frac{J(u^{h'}(.)) - J(\bar{u}(.))}{h' - h} = - \int_{[S,T]} p^T_h(t) d\mu^h(t, \bar{x}(t)). \tag{5.8}
\]

**Discussion:** The property that the sensitivity function \( h \to J(u^h) \) is differentiable when \( \bar{u}(.) \) has bounded variation and continuous at the two end-times (part (c) of the proposition) is highly non-trivial, since \( f(x, u) \) is not assumed to be differentiable w.r.t. \( u \). To convey the nature of this property in simplest terms, let us consider the case of control system (S) when \( f(x, u) \) is independent of \( x \) (write the function \( f(u) \).) Assume that

(a): \( f(.) \) is Lipschitz continuous

(b): \( \bar{u}(.) \) is continuously differentiable

It is straightforward to show that, under these hypotheses, the sensitivity function \( V(h) := J(u^h) \) is Lipschitz continuous. A standard analysis based on perturbing \( h \) and using the properties of Clarke’s generalized directional derivative (see [6, Proof of Thm. 2.7.3], for example) and a nonsmooth chain rule permits one to derive the following estimate of the subdifferential of \( V(.) \) at 0:
\[
\partial V(0) \subset - \int_S^T \co \partial_u H(p(t), \bar{u}(t)) \bar{u}(t) dt . \tag{5.9}
\]

in which
\[
H(p, u) := p^T f(u) .
\]

Here \( \partial_u H(u, p) \) denotes the subdifferential w.r.t. the \( u \) variable, for fixed \( p \). (We refer to the end of Section 1 for definition the subdifferential.) \( p(.) \) is the solution of the adjoint system \([5.4]\). The right side of this relation is a set value integral, defined in the usual way as the collection of integrals of selectors of the set valued integrand.

The proposition tells us, contrary to what the standard analysis leading to the formula \([5.9]\) might lead us to expect, the sensitivity function is actually differentiable on a neighborhood of 0.

**Proof.** We treat the case \( h \geq 0 \). (The analysis for \( h < 0 \) is similar.) We have
\[
\int_{[S,T]} |f(\bar{x}(t), u^h(t)) - f(\bar{x}, \bar{u}(t))| dt \\
\leq k_1 \left( \int_{[S,T]} (\eta_u(t) - \eta_u((t - h) \vee S)) dt \right) \\
= k_1 \left( \int_{[T-h],T} \eta_u(t) dt - \int_{[S,S+h]} \eta_u(t) dt \right) \leq 2k_1 \times \eta_u(T) \times h .
\]
By Filippov’s Existence Theorem \[13\] Thm. 2.4.3, there exist a number \(K_1\), independent of \(h\), such that

\[\|x^h(\cdot) - \bar{x}(\cdot)\|_{L^\infty} \leq K_1 \times h. \tag{5.10}\]

Under hypothesis (C2) there exists a unique solution to the differential equation \(x^h(\cdot)\) for each \(h\) and, for each \(h\) sufficiently small the graph of \(x^h(\cdot)\) lies in the open \(\delta\) tube about \(\bar{x}(\cdot)\). It can be deduced from (C3) that, for some \(h > 0\) and all \(h\), \(|h| \leq \bar{h}\), \(t \to m^h(t,.) = f(., u^h(t))\) and \(t \to m^h(t,.) = \nabla_x f(., u^h(t))\) have bounded variation along \(x^h(\cdot)\). Write the cumulative variation functions \(\eta(\cdot)\) and \(\bar{\eta}(\cdot)\), and their \(\delta\)-perturbed versions \(\eta^\delta(\cdot)\), etc.

We now examine the one-sided differentiability properties of \(h' \to J(u'^h)\) at any point \(h\), \(|h| \leq \bar{h}\). We show ‘differentiability from the right’ and confirm the formula (5.6). Without loss of generality we can assume that the base point \(h = 0\). Write \(p(\cdot) := p_{h=0}(\cdot)\).

Take an arbitrary sequence \(h_i \downarrow 0\). Then, for each \(i\),

\[
J(u^{h_i}(\cdot)) - J(\bar{u}(\cdot)) \quad = \quad g(x^{h_i}(T)) - g(\bar{x}(T)) - \int_{[S,T]} p^T(t) \left[ (\dot{x}^{h_i}(t) - \dot{\bar{x}}(t)) \right. \\
\left. - \left( f(x^{h_i}(t), u^{h_i}(t)) - f(\bar{x}(t), \bar{u}(t)) \right) \right] dt.
\]

A routine analysis, in which we make use of the costate equation and right boundary condition (5.4) on \(p(\cdot)\), apply integration by parts to the integral \(\int_{[S,T]} p^T(t)(\dot{x}^{h_i}(t) - \dot{\bar{x}}(t))dt\) and consider first order Taylor expansions of \(g(\cdot)\) about \(\bar{x}(T)\) and of \(x \to f(x, u^h(\cdot))\) about \(\bar{x}(t)\), reveals that

\[
h_i^{-1} \left( J(u^{h_i}(\cdot)) - J(\bar{u}(\cdot)) \right) = \int_{[S,T]} p^T(t) \left[ m^0((t - h_i) \vee S), \bar{x}(t) \right] dt + e(h_i), \tag{5.11}
\]

in which the ‘error term’ \(e(h_i)\) satisfies \(|e(h_i)| \leq \|p(\cdot)\|_{L^\infty} \times \theta(K_1 h_i) \times \bar{K}_1 \theta_2(K_1 h_i) K_1\).

\((\theta_g(\cdot)\) is a ‘modulus’ such that \(|g(x) - g(x') - \nabla g(x')(x-x')| < \theta_g(|x-x'|) |x-x'|\) for all \(x,x' \in \bar{x}(T) + \delta \mathbb{B}\).) We see

\[e(h_i) \to 0 \text{ as } h_i \to 0. \tag{5.12}\]

Take any \(\delta > 0\) such that \(\bar{\eta}^\delta(T) < \infty\). There exists a subset \(\mathcal{O} \subset (S, T)\) with the property: for each \(t \in \mathcal{O}\), \(t\) is a continuity point of the monotone function \(\eta^\delta(\cdot)\). Prop. 4.3 tells us that, for each \(t \in \mathcal{O}\) and \(i\) sufficiently large,

\[
m^0((t - h_i) \vee S), \bar{x}(.) \) - \( m(t, \bar{x}(t)) \) \quad = \quad - \int_{[t-h_i) \vee S,t]} ds m^0(s, \bar{x}(s)) + e_1(t, h_i) \tag{5.13}
\]

26
in which the ‘error term’ $e_1(t, h_i)$ satisfies
\[ |e_1(t, h_i)| \leq \theta_x(|h_i|) \left( \tilde{\eta}^\delta(t) - \tilde{\eta}^\delta((t - h_i) \lor S) \right). \]  
(5.14)

It follows that
\[
\begin{align*}
\frac{1}{h_i} \int_{[S,T]} p^T(t)e_2(t, h_i)dt \\
&\leq \frac{1}{h_i} \theta_x(|h_i|) \times ||p(.)||_{L^\infty} \times \int_{[S,T]} \left( \tilde{\eta}^\delta(t) - \tilde{\eta}^\delta((t - h_i) \lor S) \right) dt \\
&= \theta_x(|h_i|) \times ||p(.)||_{L^\infty} \times \left( \frac{1}{h_i} \int_{T-h_i, T} \tilde{\eta}^\delta(t)dt + \tilde{\eta}(S) \right) \to 0 \quad (5.15)
\end{align*}
\]
as $i \to \infty$. In consequence of Fubini’s Theorem
\[
\begin{align*}
\frac{1}{h_i} \int_{[S,T]} \int_{[(t-h_i) \lor S, t]} p^T(t)d_\delta m^0(s, \bar{x}(s))ds = \frac{1}{h_i} \int_{[S,T]} p^T_i(s)d_\delta m^0(s, \bar{x}(s))ds \\
in which
p_i(s) := \int_{[s, (s+h_i) \land T]} p(t)dt \quad \text{for } s \in [S, T].
\end{align*}
\]
Since $p(.)$ is continuous, $p_i(t) \to \tilde{p}(t)$ for all $t \in [S, T]$, where
\[
\tilde{p}(t) \to \begin{cases} p(t) & \text{if } t \in [S, T) \\
0 & \text{if } t = T. \end{cases}
\]
By the Dominated Convergence Theorem
\[
\begin{align*}
\frac{1}{h_i} \int_{[S,T]} \int_{[(t-h_i) \lor S, t]} p^T(t)d_\delta m^0(s, \bar{x}(s))ds \\
&\to \int_{[S,T]} \tilde{p}^T(s)d_\delta m^0(s, \bar{x}(s))ds \\
&= \int_{[S,T]} p^T(s)d_\delta m^0(s, \bar{x}(s))ds \quad (5.16)
\end{align*}
\]
Combining relations (5.11) - (5.15), we arrive at
\[
\frac{1}{h_i} \left( J(u^h_i(.)) - J(\bar{u}(.)) \right) \to - \int_{[S,T]} p^T(s)d_\delta m^0(s, \bar{x}(s))ds.
\]
We have confirmed formula (5.6) and the existence of the limit. The formula (5.7), relating to differentiability from the right, is derived in a similar manner.

We now attend to the final assertion of the proposition. Suppose then that $\bar{u}(.)$ is continuous at $S$ and $T$. Then, for $h$ sufficiently small, $t \to m^h(t, x)$ is continuous at $t = S$ and $t = T$, uniformly as $x$ ranges over neighborhoods of $x^h(S)$ and $x^h(T)$. But then it can be deduced from relation (3.8) in Prop. 3.3 (which is also valid for the cumulative variation function as well as the $\delta$-perturbed cumulative variation...
function as observed at the end of the proposition statement) that $\eta(.)$ is right and left continuous at $S$ and $T$. Then, by Prop. 4.3 $d_t m^h(.,x^h(t))$ has no atom at either $S$ or $T$. The differentiability of $h' \rightarrow J(u^h(\cdot))$ and the formula (5.8) now follow from (5.6) and (5.7), since the integrals in the latter formulae, over $[S,T)$ and $(S,T]$ respectively, are the same.
