We report results of a study of doubly charmed baryons and charmed strange baryons. The analysis is performed using a 980 fb\(^{-1}\) data sample collected with the Belle detector at the KEKB asymmetric-energy \(e^+e^-\) collider. We search for doubly charmed baryons \(\Xi^{+(-)}_{cc}\) with the \(\Lambda_c^-K^+\) final state. No significant signal is observed. We also search for two excited charmed strange baryons, \(\Xi_c(3055)^+\) and \(\Xi_c(3123)^+\), with the \(\Sigma_c^+(2455)K^-\) and \(\Sigma_c^+(2520)K^-\) final states. The \(\Xi_c(3055)^+\) signal is observed with a significance of 6.6 standard deviations including systematic uncertainty, while no signal is seen. We also study properties of the \(\Xi(2645)^+\) and measure a width of \(2.6 \pm 0.2\) (stat) \(\pm 0.4\) (syst) MeV/\(c^2\), which is the first significant determination.

I. INTRODUCTION

In recent years, there has been significant progress in charmed baryon spectroscopy, mainly by the Belle and BaBar experiments. In particular, all the ground states of the single-charmed baryons predicted by the constituent quark model and several excited states have
been observed \[9\]. However, there are no experimentally established doubly-charmed baryons. The lightest doubly-charmed baryon contains two charm quarks and one up or down quark (\(\Xi_{cc}^+ = ccc\), \(\Xi_{cc}^{0+} = ccu\)), and the spin-parity of the ground state is expected to be \(\frac{1}{2}^+\). The mass of the \(\Xi_{cc}\) has been extensively studied theoretically, and the prediction of the quark model ranges from 3.48 GeV/c\(^2\) to 3.74 GeV/c\(^2\) \[10,22\], whereas the mass predicted by lattice QCD ranges from 3.51 GeV/c\(^2\) to 3.67 GeV/c\(^2\) \[23,24\]. The cross sections of the \(\Xi_{cc}\) production in the process \(e^+e^- \rightarrow \Xi_{cc}X\) at \(\sqrt{s} = 10.58\) GeV, where \(X\) denotes the remaining particles produced in the fragmentation, is predicted to be 70 fb in Ref. \[23\] and 230 fb in Ref. \[29\]. The cross section of the pair production of the \(cc\) and \(\bar{c}\bar{c}\) diquarks is predicted to be 7 fb \[34\].

There have been several experimental studies to search for the \(\Xi_{cc}\). The SELEX collaboration reported evidence for the \(\Xi_{cc}^{+}\) in the \(\Lambda_c^+K^-\pi^+\) and \(pD^+K^-\) final states with a mass of about 3.52 GeV/c\(^2\) using a 600 GeV/c charged hyperon beam. However, the results have not been supported by FOCUS \[23\], BaBar \[31\], Belle \[2\], nor LHCb \[35\]. The BaBar collaboration searched for the \(\Xi_{cc}^{(+)}\) in the \(\Lambda_c^+K^-\pi^+\) and \(\Xi_0^0\pi^+(\pi^+)\) decay modes with a 232 fb\(^{-1}\) data sample of \(e^+e^-\) collisions at or near the \(\Upsilon(4S)\). They found no evidence for the \(\Xi_{cc}^{(++)}\) and set an upper limit on the product of the production cross section and branching fractions of the \(\Xi_{cc}\) and \(\Lambda_c^+\) or \(\Xi_0^0\) to be a few fb, depending on the decay mode. In our search for the \(\Xi_{cc}^+\) in the \(\Lambda_c^+K^-\pi^+\) final state with a 462 fb\(^{-1}\) data sample of Belle at or near the \(\Upsilon(4S)\) \[2\]. Belle also found no evidence for the \(\Xi_{cc}^+\) and set an upper limit on \(\sigma(e^+e^- \rightarrow \Xi_{cc}^+X) \times B(\Xi_{cc}^+ \rightarrow \Lambda_c^+K^-\pi^+)/(\sigma(e^+e^- \rightarrow \Lambda_c^+)X)\) of \(1.5 \times 10^{-4}\) with a \(p^*(\Lambda_c^+) > 2.5\) GeV/c requirement. Here, \(p^*(\Lambda_c^+)\) is the momentum of the \(\Lambda_c^+\) in the center-of-mass (CM) frame.

In this paper, we report on an improved search for the \(\Xi_{cc}\) in its weak decays to the \(\Lambda_c^+K^-\pi^+\) and \(\Xi_0^0\pi^+(\pi^+)\) final states. The Belle collaboration has collected a data sample with a total integrated luminosity of 980 fb\(^{-1}\), which is around two (four) times the statistics of the previous \(\Xi_{cc}\) search by Belle \[2\] (BaBar \[31\]) and supersedes the results in Ref. \[2\]. Furthermore, in the previous studies, the \(\Lambda_c^+\) and the \(\Xi_0^0\) states have been reconstructed only from decay modes of \(pK^-\pi^+\) and \(\Xi^-\pi^+\), respectively. We incorporate additional decay modes to improve the statistical sensitivity.

The same data sample can be used to study charmed strange baryons, as the \(\Lambda_c^+K^-\pi^+\) and the \(\Xi_0^0\pi^+\) final states are strong decay modes of excited \(\Xi_{cc}^+\) (\(\Xi_{cc}^{(++)}\)) states. The BaBar collaboration found two \(\Xi_{cc}^+\) states, \(\Xi_1(3055)^+\) and \(\Xi_2(3123)^+\), decaying to the \(\Lambda_c^+K^-\pi^+\) final state through intermediate \(\Sigma_c(2455)^{++}\) or \(\Sigma_c(2520)^{++}\) states using a data sample of 384 fb\(^{-1}\) \[9\]. Their statistical significance was 6.4 standard deviations \((\sigma)\) and 3.6\(\sigma\), respectively. A confirmation of these states in other experiments is necessary. The \(\Xi_{cc}^0\pi^+\) is a strong decay mode of the \(\Xi_{cc}(2645)^+\). Currently, the upper limit of 3.1 MeV/c\(^2\) exists for its width \[36\]. In this paper, we also report on a search for the \(\Xi_{cc}(3055)^+\) and \(\Xi_2(3123)^+\) in the \(\Lambda_c^+K^-\pi^+\) final state, and the measurement of the width of the \(\Xi_{cc}(2645)^+\).

The remaining sections of the paper are organized as follows. In section III the data samples and the Belle detector are described. In section IV a study of the final states with \(\Lambda_c^+\), i.e., the \(\Xi_{cc}\) search and the \(\Xi_1(3055)^+\) and \(\Xi_2(3123)^+\) search, are reported. In section V a study of the final state with \(\Xi_{cc}^0\), i.e., the \(\Xi_{cc}\) search and measurement of the width of the \(\Xi_{cc}(2645)^+\), are described. Finally, conclusions are given in section VI.

II. DATA SAMPLES AND THE BELLE DETECTOR

We use a data sample with a total integrated luminosity of 980 fb\(^{-1}\) recorded with the Belle detector at the KEKB asymmetric-energy e\(^+\)e\(^-\) collider \[37\]. The data samples with different beam energies at or near the \(\Upsilon(1S)\) to \(\Upsilon(5S)\) are combined in this study. The beam energies and integrated luminosities are summarized in Table I. The luminosity-weighted average of \(\sqrt{s}\) is 10.59 GeV.

The Belle detector is a large-solid-angle magnetic spectrometer that consists of a silicon vertex detector (SVD), a 50-layer central drift chamber (CDC), an array of aerogel threshold Cherenkov counters (ACC), a barrel-like arrangement of time-of-flight scintillation counters (TOF), and an electromagnetic calorimeter comprised of CsI(Tl) crystals (ECL) located inside a superconducting solenoid coil that provides a 1.5 T magnetic field. An iron flux return located outside of the coil is instrumented to detect \(K_L^0\) mesons and to identify muons (KLM). The detector is described in detail elsewhere \[38\]. Two inner detector configurations were used. A 2.0 cm radius beampipe and a 3-layer silicon vertex detector were used for the first sample of 156 fb\(^{-1}\), while a 1.5 cm radius beampipe, a 4-layer silicon detector and a small-cell inner drift chamber were used to record the remaining 824 fb\(^{-1}\) \[39\].

The selection of charged hadrons is based on information from the tracking system (SVD and CDC) and hadron identification system (CDC, ACC, and TOF). The charged proton, kaon, and pion that is not associated with long-lived particles like \(K_L^0\), \(\Lambda\) and \(\Xi^-\), is required to have a point of closest approach to the interaction point that is within 0.2 cm in the transverse \((r-\phi)\) direction and within 2 cm along the z-axis. (The z-axis is opposite the positron beam direction.) For each track, the likelihood values \(L_p\), \(L_K\), and \(L_\pi\) are provided for the assumption of proton, kaon and pion, respectively, from the hadron identification system, based on the ionization energy loss in the CDC, the number of detected Cherenkov photons in the ACC, and the time of flight measured by the the TOF. The likelihood ratio is de-
defined as $\mathcal{L}(i : j) = L_i / (L_i + L_j)$ and a track is identified as a proton if the likelihood ratios $L(p : \pi)$ and $L(p : K)$ are greater than 0.6. A track is identified as a kaon if the likelihood ratios $L(K : \pi)$ and $L(K : p)$ are greater than 0.6. A track is identified as a pion if the likelihood ratios $L(\pi : K)$ and $L(\pi : p)$ are greater than 0.6. In addition, electron ($L_e$) likelihood is provided based on information from the ECL, ACC, and CDC. A track with an electron likelihood greater than 0.95 is rejected.

The momentum averaged efficiencies of hadron identification are about 90%, 90%, and 93% for pions, kaons and protons, respectively. The momentum averaged probability to misidentify a pion or kaon track as a proton track is about 5%.

We use a Monte-Carlo (MC) simulation events generated with EVTGEN [41], JETSET [42] with final QED final state radiation by PHOTOS [43] and then processed by a GEANT3 [44] based detector simulation to obtain the reconstruction efficiency and the mass resolution.

III. FINAL STATE WITH THE $\Lambda_c^+$

In this section, the analysis using the final states with the $\Lambda_c^+$ baryon is described. Reconstruction of the $\Lambda_c^+$ candidate is explained first, followed by the description of the $\Xi_{cc}^{(+)}$ search in its decay into $\Lambda_c^+ K^- \pi^+(\pi^+)$ and the study of two charmed strange baryons, $\Xi_c(3055)^+$ and $\Xi_c(3123)^+$. Throughout this paper, the selection criteria are determined to maximize the figure of merit (FOM), defined as $\epsilon / \sqrt{N_{BG}}$, where $\epsilon$ is the $\Xi_{cc}$ efficiency for the selection criteria and $N_{BG}$ is the number of background events under the signal peak except for the scaled momentum selection for $\Xi_c(3055)^+$ and $\Xi_c(3123)^+$ search, which followed BaBar’s analysis. The distribution of background events is estimated based on data. When the selection criteria are determined, we hide the possible signal peak by smearing invariant mass of the $\Xi_{cc}$ candidates event by event with a Gaussian having a 50 MeV/c$^2$ width in order to avoid any biases.

A. Reconstruction of the $\Lambda_c^+$

The $\Lambda_c^+$ candidates are reconstructed in the $pK^-\pi^+$ and $pK_S^0$ decay modes [45]. The $K_S^0$ candidate is reconstructed from its decay into $\pi^+\pi^-$. A pair of oppositely charged pions that have an invariant mass within 8 MeV/c$^2$ of the nominal $K_S^0$ mass, which corresponds to approximately $3.5\sigma$ of the mass resolution, is used. Two pion tracks are fitted to a common vertex. The result of the fit is used to suppress misreconstructed $K_S^0$ candidates and to perform further vertex fit of the $\Lambda_c^+ \to pK_S^0$. The vertex of the two pions for the $K_S^0$ is required to be displaced from the interaction point (IP) in the direction of the pion pair momentum [46]. The daughters of the $\Lambda_c^+$ are fitted to a common vertex; the invariant mass of the daughters must be within 5 (6) MeV/c$^2$, or $1.5\sigma$, nominal $\Lambda_c^+$ mass for the $pK^-\pi^+$ ($pK_S^0$) decay mode. The $\chi^2$ value of the common vertex fit of the $\Lambda_c^+$ is required to be less than 50. For the remaining candidate, a mass constraint fit to the $\Lambda_c^+$ mass is performed to improve the momentum resolution. As the signal-to-background ratio for the $\Lambda_c^+$ candidates is similar for the $pK^-\pi^+$ and $pK_S^0$ decay modes, they are combined in the following analysis. By including the $pK_S^0$ mode in addition to the $pK^-\pi^+$ mode, the yield of the $\Lambda_c^+$ is increased by about 20%.

B. Search for doubly charmed baryons in $\Lambda_c^+ K^-\pi^+(\pi^+)$

We search for the $\Xi_{cc}^{(+)}$ in its decay into $\Lambda_c^+ K^-\pi^+(\pi^+)$ in the mass range of 3.2-4.0 GeV/c$^2$. The expected mass resolution of the $\Xi_{cc}$ estimated from MC is 2.0-3.5 MeV/c$^2$, depending on the mass of the $\Xi_{cc}$ (degrading with increasing mass). In order to reduce the combinatorial background, a selection on the scaled momentum $x_p = p^*/\sqrt{s/4 - m^2}$ is used, where $p^*$ is the CM momentum of a $\Xi_{cc}$ candidate and $s$ is CM energy squared and $m$ is mass of the $\Xi_{cc}$ candidate. As there is no measurement of the $x_p$ spectrum for $\Xi_{cc}$ production, we assume it to be the same as that of the $\Lambda_c^+$, which has been precisely measured [47]. The $x_p$ spectrum is represented by a smooth polynomial function and is used to generate a MC sample for the $\Xi_{cc}$ signal. Decays of the $\Xi_{cc}$ and $\Lambda_c^+$ are generated according to the available phase space distribution. The number of background events as a function of the $x_p$ cut is estimated based on smeared data. The FOM as a function of the $x_p$ cut is surveyed in the search region. The optimization procedure yields $0.5 < x_p < 1.0$ regardless of the $\Xi_{cc}$ mass. To check the validity of our analysis, we independently examine the $x_p$ spectrum of the $\Lambda_c^+$ and confirm that it is consistent with that presented in Ref. [47].

Figure 7 (a) and (b) show the $M(\Lambda_c^+ K^-\pi^+)$ and $M(\Lambda_c^+ K^-\pi^+\pi^+)$ distributions, respectively, for data after all the event selections applied. No significant signal is seen in the data for either $\Xi_{cc}$ or $\Xi_{cc}^+$. The statistical significance for a given mass is evaluated with an unbinned extended maximum likelihood (UML) fit. The probability density function (PDF) for the signal is described with signal MC generated for each given $\Xi_{cc}$ mass, whereas a third-order polynomial function is used as the background PDF. The statistical significance is defined as $-2\ln(\mathcal{L}_0 / \mathcal{L})$, where $\mathcal{L}_0$ is the likelihood for the fit without the signal component and $\mathcal{L}$ is the likelihood for the fit with the signal component included. The significance is evaluated for the $\Xi_{cc}$ mass scanned with a 1 MeV/c$^2$ step in the search region. None of the mass points give a significance exceeding the $3\sigma$ level.
The 95% confidence level (C.L.) upper limit for the product of the cross section and branching fraction to the $\Lambda_c^-K^+\pi^+(\pi^+)\bar{\pi}$ state produced with the 0.5 $< x_p < 1.0$ condition,  
\[
\sigma_B \equiv \sigma(e^+e^- \rightarrow \Xi_{cc}^{+(+)}X) \times B(\Xi_{cc}^{+(+)} \rightarrow \Lambda_c^+K^-\pi^+(\pi^+)) = \frac{2LB_{pK^-\pi^+}(\epsilon_{pK^-\pi^+} + \epsilon_{pK_S}B_{pK_S}/B_{p\bar{K}^-})}{N_{\text{sig}}}
\]

is evaluated. Here, $L$ is the total integrated luminosity, $N_{\text{sig}}$ is the $\Xi_{cc}$ signal yield, $B_{pK^-\pi^+}$ is the branching fraction of the $\Lambda_c^+ \rightarrow pK^-\pi^+(\pi^+)$ (which amounts to 0.050 $\pm$ 0.013), $B_{pK_S}$ is the branching fraction of $\Lambda_c^+ \rightarrow pK^0$ measured relative to the $pK^-\pi^+$ mode ($B_{pK_S}/B_{p\bar{K}^-} = 0.24 \pm 0.02$), and $\epsilon_{pK^-\pi^+}(pK_S)$ is the reconstruction efficiency for the $\Lambda_c^+ \rightarrow pK^-\pi^+$ (and $\Lambda_c^+ \rightarrow pK^0$) decay mode evaluated as a function of the $\Xi_{cc}$ mass. The efficiencies for the $\Xi_{cc}^{+(+)}$ as a function of their masses are shown in Fig. 2. The factor of two in the denominator comes from inclusion of the charge-conjugate mode. By including this factor, our measurement can be compared with the theoretical predictions [28, 29]; while to compare with the prediction in Ref. [30], it is necessary to multiply our $\sigma_B$ measurement by 2 because they predicted the cross section of the pair production of the $c\bar{c}$ and $\bar{c}c$ diquarks. In BaBar’s measurement [34], they do not introduce the factor of two (i.e., they report an upper limit for the sum of the $\sigma(e^+e^- \rightarrow \Xi_{cc}^{+(+)}X)$ and its charge-conjugate mode). Therefore, our measurement should be doubled when comparing with BaBar’s result. We note that the cross section reported here and elsewhere in this paper is a visible cross section (i.e., a radiative correction is not applied).

The upper limit is evaluated following the Bayesian approach. First, we scan the likelihood profile by determining the likelihood values as a function of the $\sigma_B$ (i.e., $L(\sigma_B)$), varying $N_{\text{sig}}$ from zero up to the $N_{\text{sig}}$ value for which the likelihood drops to zero. Then, $L(\sigma_B)$ is convolved with a Gaussian whose width equals the systematic uncertainties of $\sigma_B$. The $\sigma_B$ value for which the integral (starting from $\sigma_B = 0$) becomes 95% of the entire area is regarded

---

**TABLE I: Summary of the integrated luminosities and beam energies.**

| $\sqrt{s}$ | $\Upsilon(5S)/$near it | $\Upsilon(4S)/$near it | $\Upsilon(3S)/$near it | $\Upsilon(2S)/$near it | $\Upsilon(1S)/$near it |
|---|---|---|---|---|---|
| Integrated luminosity (fb$^{-1}$) | 121.0/29.3 | 702.6/89.5 | 2.9/0.3 | 24.9/1.8 | 5.7/1.8 |
as the 95% C.L. upper limit.

We consider the following systematic uncertainties in the \( \Xi_{cc} \) search. The systematic uncertainty due to the efficiency of pion and kaon identification is estimated from the ratio of the yield of the \( D^{*+} \rightarrow D^0 \pi^+ \), \( D^0 \rightarrow K^- \pi^+ \) with and without the pion/kaon identification requirements for data and MC. The difference of the ratio between data and MC is corrected and the statistical error of the ratio is regarded as the systematic uncertainty. The systematic uncertainty due to the efficiency of proton identification is estimated using the ratio of the yield of the \( \Lambda \rightarrow p \pi^- \) with and without the proton identification requirement. The difference of the ratio between data and MC is corrected and the statistical error of the ratio is regarded as the systematic uncertainty. The systematic uncertainty due to the efficiency of pion and kaon identification is estimated from the ratio of the yield of the \( \Lambda \rightarrow p \pi^- \) with and without the proton identification requirement. The difference of the ratio between data and MC is corrected and the statistical error of the ratio is regarded as the systematic uncertainty. The systematic uncertainty due to the charged track reconstruction efficiency is estimated using the decay chain \( D^{*+} \rightarrow D^0 \pi^+ \), \( D^0 \rightarrow \pi^+ \pi^- K^0_S \), and \( K^0_S \rightarrow \pi^+ \pi^- \), where \( K^0_S \rightarrow \pi^+ \pi^- \) is either partially or fully reconstructed. The ratio of the yields for partially and fully reconstructed signals in data and MC is compared, and the difference is taken as the systematic uncertainty. This amounts to 0.35% per track. The systematic uncertainty of the total integrated luminosity is 1.4%. To check the systematic error due to the signal PDF, we compare the mass resolution of the \( \Lambda_c^+ \) in data and MC. We find that the resolution for data is 5% larger than in MC. To monitor the effect of this discrepancy, we perform a pseudo-experiment test in which we extract the signal yield with correct PDF and one that is narrower by 5%. The largest difference of 3% measured in this test is regarded as the systematic uncertainty. The systematic uncertainty related to the \( \Lambda_c^+ \) branching fraction is propagated from the errors taken from the PDG [9]. To estimate the systematic uncertainty of the reconstruction efficiency due to the possible difference of \( x_p \) spectrum between our assumption (the same as that of \( \Lambda_c^+ \)) and actual one, we examine the \( x_p \) dependence of the reconstruction efficiency. The root mean square of the reconstruction efficiency in the region of \( 0.5 < x_p < 1.0 \) is regarded as the systematic uncertainty. The elements of the systematic uncertainty for the measurement of the \( \sigma_B \) are enumerated in the first and second columns of Table 11.

Figures 1(c) and (d) show the 95% C.L. upper limit on \( \sigma_B \) for \( \Xi_{cc}^+ \) and \( \Xi_{cc}^{++} \), respectively, as a function of the mass with a 1 MeV/c^2 step. The upper limit is in the range of 4.1–25.0 fb for the \( \Xi_{cc}^+ \) and 2.5–26.5 fb for the \( \Xi_{cc}^{++} \).

C. Search for the \( \Xi_{cc}^+ (3055) \) and \( \Xi_{cc}^+ (3123) \)

In this section, a search for the \( \Xi_{cc}^+ (3055) \) and \( \Xi_{cc}^+ (3123) \) is described. Here, we require \( x_p \) to be greater than 0.7. In the analysis by BaBar [6], they required \( p^*(\Lambda_c^+ K^- \pi^+) > 2.9 \) GeV/c, which is similar to our \( x_p \) cut as illustrated by the \( p^*(\Lambda_c^+ K^- \pi^+) \) distribution, with the \( x_p \) cut and 2.9 GeV/c^2 < \( M(\Lambda_c^+ K^- \pi^+) < 3.2 \) GeV/c^2 required as shown in Fig. 3(a). Figure 3(b) shows the \( M(\Lambda_c^+ \pi^+) \) distribution, where contributions from the \( \Sigma_\pi (2455)^{++} \) and the \( \Sigma_\pi (2520)^{++} \) baryons are clearly visible. We select the \( \Sigma_\pi (2455)^{++} \) (\( \Sigma_\pi (2520)^{++} \)) region by requiring \( |M(\Lambda_c^+ \pi^+)-(m_{\Sigma_\pi^{++}})| < 5 \) (18) MeV/c^2, where \( m_{\Sigma_\pi^{++}} \) is the nominal mass of the \( \Sigma_\pi (2455)^{++} \) or \( \Sigma_\pi (2520)^{++} \).

Figure 3(c) shows the \( M(\Lambda_c^+ K^- \pi^+) \) distribution for the \( \Xi_{cc} (3055)^+ \) signal region together with the same plot for the \( \Xi_{cc} (2520)^{++} \) sideband region, defined as \( |M(\Lambda_c^+ \pi^+)-(m_{\Sigma_\pi (2455)^{++}})\pm 15 \) MeV/c^2 | < 5 MeV/c^2. Clear peaks corresponding to the \( \Xi_{cc} (2980)^+, \Xi_{cc} (3055)^+ \) and \( \Xi_{cc} (3080)^+ \) are seen. To obtain the statistical significance of the \( \Xi_{cc} (3055)^+ \), an UML fit is applied. PDFs for the \( \Xi_{cc}^+ \) components are represented by a Breit-Wigner line-shape convolved with a Gaussian to account for the invariant-mass resolution (\( \sigma_{m}\)). Using the signal MC events, we estimate \( \sigma_{m} \) to vary from 1.2 to 1.8 MeV/c^2, depending on the masses of the \( \Xi_{cc}^+ \) states. The width and mean of the Breit-Wigner functions are treated as free parameters. The background PDF, \( f_1(x) \), is modeled with a threshold function:

\[
\begin{align*}
 f_1(x) &= 1 - \exp((x - x_0)/\delta_m)(x/x_0)^a \\
 &\quad + b(x/x_0 - 1) \quad (\text{if } x > x_0) \\
 f_1(x) &= 0 \quad (\text{if } x < x_0),
\end{align*}
\]

where \( a, b, x_0, \) and \( \delta_m \) are free parameters in the fit.

The fit result is shown in Fig. 3(c). To estimate the statistical significance of the \( \Xi_{cc} (3055)^+ \), we compare the likelihood values for the fits with and without the \( \Xi_{cc} (3055)^+ \) component. The obtained \(-2 \ln (L_0/L)\) value is 54.7. By taking into account the change of the number of degrees of freedom (\( ndf \)) by the inclusion of the \( \Xi_{cc} (3055)^+ \) component, the statistical significance of the \( \Xi_{cc} (3055)^+ \) becomes 6.8. The \( \chi^2/ndf \) of the fit for the \( \Xi_{cc} (3055)^+ \) component, for the binning of Fig. 3(c), is 54.8/61.

Figure 3(d) shows the \( M(\Lambda_c^+ K^- \pi^+) \) distribution for the \( \Xi_{cc} (2520)^{++} \) selected region together with the same plot for the \( \Xi_{cc} (2520)^{++} \) sideband region, defined as \( |M(\Lambda_c^+ \pi^+)-(m_{\Sigma_\pi (2520)^{++}})\pm 27 \) MeV/c^2 | < 12 MeV/c^2. A clear peak corresponding to the \( \Xi_{cc} (3080)^+ \) is seen, while no peak structure is seen in the mass near 3.123 GeV/c^2. An UML fit is applied to extract the signal yield. Again, the \( \Xi_{cc}^+ \) components are represented by a Breit-Wigner function convolved with a Gaussian. For the \( \Xi_{cc} (3080)^+ \) component, the mass and width of the Breit-Wigner are treated as free parameters; while for the \( \Xi_{cc} (3123)^+ \) component, the mass and width are fixed to the values obtained in Ref. [6]. The background shape, \( f_2(x) \), is assumed to be:

\[
\begin{align*}
 f_2(x) &= (1 - \exp((x - x_0^2)/\delta_m))(x/x_0)^a \\
 &\quad + b(x/x_0 - 1) + c((x/x_0)^2 - 1) \quad (\text{if } x > x_0) \\
 f_2(x) &= 0 \quad (\text{if } x < x_0),
\end{align*}
\]
where $a$, $b$, $c$, $x_0$, and $\delta_m$ are fit parameters. The $\chi^2/ndf$ of the fit with the $\Xi_c(3123)^+$ component for the binning of Fig. 8(d) is 28.6/42. The yield of the $\Xi_c(3123)^+$ is 8 ± 22 events, which is consistent with zero. Hence, a 95% C.L. upper limit for the production cross section is evaluated with the method described in the previous section. To directly compare with the BaBar result in Ref. [6], the upper limit for the product of the cross section and branching fraction of $\Lambda_c^+$ is evaluated with the $\Xi_c^+$ data. The ratio of the generated and extracted yield is regarded as a systematic uncertainty. Because the error of the width is relatively large, its systematic uncertainty contribution is dominant (28%). All of the systematic errors are summarized in the third column of Table II. The 95% C.L. upper limit on $\sigma_{BA^+}$ is 0.17 fb. As in the case of the $\Xi_c$ cross section, the measurement in Ref. [6] does not introduce a factor of two for the $\sigma_{BA^+}$ calculation. Therefore, we should double our measurement, which results in 0.34 fb, when comparing with BaBar’s result. The value is much smaller than that quoted in Ref. [6] (1.6 ± 0.6 ± 0.2 fb).

The systematic uncertainties of the masses and widths of the $\Xi_c^{++}$ and stability of the statistical significance of the $\Xi_c(3055)^+$ are studied by the following fitting configurations. The systematic uncertainties due to the signal PDF are studied by varying $\sigma_{\text{res}}$ by 5%. The systematic uncertainties due to possible interference between the $\Xi_c(3055)^+$ and $\Xi_c(3080)^+$ are studied by fitting the distribution with an additional phase parameter between the two Breit-Wigner amplitudes. The systematic uncertainty due to the background shape is studied by fitting the mass spectra with a second-order polynomial as a background PDF in the range of 3.005-3.200 GeV/$c^2$. In none of these fitting configurations does the statistical significance of the $\Xi_c(3055)^+$ fall below 6.6$\sigma$. We apply cut conditions of $x_p > 0.6$ and $x_p > 0.8$ instead of $x_p > 0.7$ and re-extract the masses and widths of the

![FIG. 2: Reconstruction efficiency as a function of the $\Xi_{cc}$ mass, for (a) $\Xi_{cc}^+$, (b) $\Xi_{cc}^{++}$. Circular points are for $\Lambda_c^+ \rightarrow pK^0\Sigma^0$. The lines show the result of the fit with a linear function.](image-url)
states. The differences from the default cut condition are regarded as systematic uncertainties. The measured masses, widths and yields of the three Ξ^{0} states are summarized in Table III. All of these measurements are consistent with previous Belle measurement [2] within 2.5σ and with the BaBar measurement [2] within 2.0σ.

IV. FINAL STATE WITH Ξ^{0}c

In this section, the analysis of the final state with the Ξ^{0}c is described. The reconstruction of the Ξ^{0}c is presented first, followed by the analysis of the Ξc(2645)++. Finally, a search for Ξ^{+}(+) decaying into the Ξ^{0}π^{+}(π^{+}) final state is described.

A. Reconstruction of Ξ^{0}c

The Ξ^{0}c is reconstructed in three decay modes: Ξ^{−}−π^{+}, ΛK−π^{+} and pK−K−π^{+}. The Λ is reconstructed from its decay into pπ−. The proton and π− tracks for Λ candidates are fitted to a common vertex. The fitting result is used to suppress misreconstructed Λ candidates and to perform the subsequent vertex fit for the Ξ^{−}−→Λπ− or Ξ^{0}c−→ΛK−π. The invariant mass of the Λ candidate is required to be within 3 MeV/c^{2} of the nominal Λ mass, which corresponds to approximately 3σ of the mass resolution. The selection based on their decay vertex information is also applied [18]. The Ξ^{−} is reconstructed from its decay into Λπ−. The Λ and π− tracks for Ξ− candidates are fitted to a common vertex. The fitting result is used to clean up the Ξ^{−}c candidates and in the common vertex fit for the Ξ^{0}c−→Ξ^{−}−π^{+}. The closest distance of the Λ and π− along the z-direction is required to be less than 3 mm. We require cosθ > 0.95, where θ is the angle between the momentum vector of the Ξ^{−} and the vector between the IP and the Ξ^{−} decay vertex. The χ^{2} of the common-vertex fit of the Λπ− is required to be less than 50. The invariant mass of a Ξ^{0}c candidate is required to be within 4 MeV/c^{2} of the nominal Ξ^{0}c mass, which corresponds to approximately 3σ of the mass resolution. The daughter particles of the Ξ^{0}c are fitted to a common vertex. The Ξ^{0}c candidates are selected by requiring invariant masses of the daughter particles with common vertex fit to be within 12, 7 and 7 MeV/c^{2} of the nominal Ξ^{0}c mass for the Ξ^{−}−π^{+}, ΛK−π^{+} and pK−K−π^{+} decay modes, respectively, which correspond to approximately 1.5σ of the mass resolution. The χ^{2} value of the common vertex fit for the Ξ^{0}c is required to be less than 50. The mass constraint fit to the Ξ^{0}c mass is performed.

We optimize the selection criteria for x_{p} in the Ξ^{0}cπ^{+}(π^{+}) system with the method described in [11] again assuming that the x_{p} spectrum for the Ξ^{0}c is the same as that for the Λ^{+}. We require 0.45 < x_{p} < 1.0 independent of the Ξ^{0}c mass and the Ξ^{0}c decay mode. The same cut is applied for the analysis of the Ξc(2645)++.

B. Study of the Ξ^{+}(2645)

Unlike the Λ^{+} study, the signal-to-background ratio of the Ξ^{0}c largely depends on the decay modes. Therefore, to improve our sensitivity for the Ξ^{0}c, we perform a simultaneous fit to the mass spectra for the three Ξ^{0}c decays with fixed relative signal ratios. We use the relative yields of the Ξc(2645)++→Ξ^{0}cπ^{+} measured for the Ξ^{0}c decay modes to estimate a relative signal yield of the Ξc(2645)++. The relative signal yields of the Ξc(2645)++ (N_{Ξ}^{0}c) in a given Ξ^{0}c decay channel can be written as

\[ N_{Ξ}^{0}c = \frac{\epsilon_{Ξ}^{f} {σ}_{Ξ}^{res}}{\epsilon_{Ξ}^{i} {σ}_{Ξ}^{res}}, \]

where N_{Ξ}^{0}c is the Ξc(2645)++ yield, \epsilon_{Ξ}^{i} is the reconstruction efficiency of the Ξ^{0}c, and \epsilon_{Ξ}^{f} is the reconstruction efficiency of the Ξc(2645)++. Both efficiencies include the secondary branching fractions for Ξ^{−}−→pπ− of (63.9 ± 0.5)% and Ξ^{−}−→Λπ− of (99.887 ± 0.035)%.

Figure 4 shows the M(Ξ^{0}cπ^{+}) distribution for each Ξ^{0}c decay mode below the Ξ^{0}c search region. Clear peaks corresponding to the Ξc(2645)++ are seen in all decay modes. The bump structures near 2.68 GeV/c^{2} originate from the process Ξc(2790)++→Ξ^{0}cπ^{+}→Ξ^{0}cγπ^{+} with a γ missing in the reconstruction. The simultaneous UML fit is applied to extract the relative yields and the width of the Ξc(2645)++. The Ξc(2645)++ signal is represented by a Breit-Wigner function convolved with a Gaussian whose width corresponds to the mass resolution \sigma_{res}. The value of \sigma_{res} is 1.05 MeV/c^{2}, independent of the decay modes of the Ξ^{0}c. The PDF of the Ξc(2790)++ reflection is modeled using MC: \epsilon_{Ξ}^{f}(x) in Eq. 2 is used as the background PDF for the Ξ^{0}c−→Ξ^{0}c−π^{+} decay mode whereas \epsilon_{Ξ}^{f}(x) in Eq. 1 is used for the Ξ^{0}c−→ΛK−π^{+} and Ξ^{0}c−→pK−K−π^{+} decay modes. The width and mass of the Ξc(2645)++ are constrained to be the same for the three decay modes.

The yield of the Ξc(2645)++ is 1298 ± 51, 1444 ± 58 and 974 ± 47 for the Ξ^{0}c, ΛK−π^{+} and pK−K−π^{+} decay modes, respectively. The mass and width are obtained to be 2645±1.0 MeV/c^{2} and 2.6 ± 0.2 MeV/c^{2}, respectively. The χ^{2}/ndf of the fit for the binning in Fig. 4 is 296/276.

To check the consistency of the width measurement between the Ξ^{0}c decay modes, we fit the three mass spectra separately. The measured widths are found to be consistent between the three decay modes: 2.9 ± 0.3 MeV/c^{2}, 2.6 ± 0.3 MeV/c^{2} and 2.5 ± 0.3 MeV/c^{2} for Ξ^{0}c−→Ξ^{−}−π^{+}, ΛK−π^{+} and pK−K−π^{+}, respectively. The measured width is found to be consistent for the three decay modes. The systematic uncertainty of the width measurement due to the fit procedure is studied with
FIG. 3: (a) The $p^*(\Lambda^c K^- \pi^+)$ distribution from data. (b) The $M(\Lambda^c \pi^+)$ distribution. The vertical lines show the selected regions of the $\Sigma_c(2455)^{++}$ and $\Sigma_c(2520)^{++}$. (c) The $M(\Lambda^c K^- \pi^+)$ distribution with $\Sigma_c(2455)^{++}$ selection. The dots with error bars show the distribution for the $\Sigma_c(2455)^{++}$ selected region whereas the rectangles show the distribution for the $\Sigma_c(2455)^{++}$ sideband region. The solid line shows the fit result. The dashed, dotted, and dash-dotted lines show the contributions from the background, $\Xi_c(3055)^+$, and $\Xi_c(3080)^+$, respectively. (d) The $M(\Lambda^c K^- \pi^+)$ distribution with $\Sigma_c(2520)^{++}$ selection. The dots with error bars show the distribution for $\Sigma_c(2520)^{++}$ selected region whereas the rectangles show the distribution for the $\Sigma_c(2520)^{++}$ sideband region. The solid line shows the fit result. The dashed, dotted, and dash-dotted lines show the contributions from the background, $\Xi_c(3123)^+$, and $\Xi_c(3080)^+$, respectively.

FIG. 4: $M(\Xi_c^0 \pi^+)$ distributions below the $\Xi_{cc}$ search region for (a) $\Xi_c^0 \rightarrow \Xi^- \pi^+$, (b) $\Xi_c^0 \rightarrow \Lambda K^- \pi^+$, (c) $\Xi_c^0 \rightarrow pK^- K^+ \pi^+$. The solid lines show the fit result. The dashed, dotted, and dash-dotted lines show the contributions from background, $\Xi_c(2645)^+$, and $\Xi_c(2790)^+$, respectively.
TABLE III: The measured masses and widths of the three $\Xi^+_c$ states. The first error is statistical and second is systematic.

| Particle | Mass (MeV/$c^2$) | Width (MeV/$c^2$) | Yield |
|----------|------------------|-------------------|-------|
| $\Xi_c(2980)^+$ | 2974.9 ± 1.5 ± 1.4 ± 2.1 14.8 ± 2.5 ± 4.1 244 ± 39 |
| $\Xi_c(3055)^+$ | 3058.1 ± 1.0 ± 2.1 9.7 ± 3.4 ± 3.3 199 ± 46 |
| $\Xi_c(3080)^+$ | 3077.9 ± 0.4 ± 0.7 3.2 ± 1.3 ± 1.3 185 ± 31 |

pseudo-experiment events samples: the $\Xi_c(2645)^+$ component is generated according to the signal MC sample with the natural width of 2.6 MeV/$c^2$ by signal MC, while contributions from background and $\Xi_c(2790)^+$ reflection are generated based on the fit result with the real data. The statistics of the pseudo-experiment samples are the same as for those of data. The width of the $\Xi_c(2645)^+$ is extracted from simultaneous fits to pseudo-experiment samples, and its mean value is obtained to be $2.75 ± 0.03$ MeV/$c^2$, which is higher than the input value by 0.15 MeV/$c^2$. The difference is included as the systematic uncertainty from the fit procedure. The systematic uncertainty due to the background shape is studied by fitting the data with a second-order polynomial function for the alternative background shape. The fit region is restricted to 2.62-2.75 GeV/$c^2$. The width is obtained to be 2.9 ± 0.2 MeV/$c^2$, which is 0.3 MeV/$c^2$ higher than the default measurement. This deviation is included as a systematic uncertainty. To check the systematic uncertainty due to the mass resolution, we evaluate the ratio of the resolution of the $\Xi^0_c$ in the data and signal MC, $\sigma_{\text{data}}/\sigma_{\text{MC}}$, where $\sigma_{\text{data}}$ is the resolution of $\Xi^0_c$ for data and $\sigma_{\text{MC}}$ is that for MC. An additional cut of 2.64 GeV/$c^2 < M(\Xi^0_c\pi^+\pi^-) < 2.65$ GeV/$c^2$ is applied to select the $\Xi_c(2645)^+$ region only. The ratio $\sigma_{\text{data}}/\sigma_{\text{MC}}$ is 0.96 ± 0.03, 1.03 ± 0.07 and 1.07 ± 0.03 for the $\Xi^0_c\pi^+$, $\Lambda K^-\pi^+$ and $pK^-K^-\pi^+$ decay modes, respectively. We assign the systematic uncertainty conservatively by increasing the mass resolution by 7%, which is the largest deviation of the $\sigma_{\text{data}}/\sigma_{\text{MC}}$ from unity, for all the decay modes. The resulting width is 2.5 ± 0.2 MeV/$c^2$. The difference of 0.1 MeV/$c^2$ with respect to the default measurement is included as a systematic uncertainty. We use alternative $x_p$ range of 0.35 < $x_p$ < 1.0 and 0.55 < $x_p$ < 1.0 and extract the width of 2.6 ±0.2 MeV/$c^2$ for the former case and 2.8 ±0.2 MeV/$c^2$ for the latter. The largest difference of 0.2 MeV/$c^2$ with respect to the default measurement is included as a systematic uncertainty. By adding all the systematic uncertainties in quadrature, the total systematic uncertainty for the width measurement is estimated to be 0.4 MeV/$c^2$.

C. Search for doubly charmed baryons in the $\Xi^0_c\pi^+(\pi^-\pi^+)$ final state

To obtain the relative yields of the $\Xi_{cc}$, $\epsilon_{\Xi_{cc}}^i$ and $\epsilon_{\Xi_c(2645)^+}^i$ are evaluated using MC, and the efficiency $\epsilon_{\Xi_{cc}}^i$ is obtained as a function of the $\Xi_{cc}$ mass. $N_{\Xi_{cc}(2645)^+}$ and $\epsilon_{\Xi_{cc}(2645)^+}^i$ are summarized in Table IV while $\epsilon_{\Xi_{cc}}^i$ as a function of $\Xi_{cc}$ mass is shown in Fig. 5. As an example, the relative yield ratio of the $\Xi_{cc}$ with a mass of 3.6 GeV/$c^2$ is $N_{\Xi_{cc}}^{3.6}\pi^+/N_{\Xi_{cc}}^{(Σ^+\pi^-)}+N_{\Xi_{cc}}^{pK^-K^-\pi^+}=1.15+0.84$.

Figure 6 (a)-(c) shows the $M(\Xi^0_c\pi^+(\pi^-\pi^+))$ distribution in the $\Xi_{cc}$ search region with all the selection cuts applied, overlaid with the MC expectation for the $\Xi_{cc}$ at the mass of 3.60 GeV/$c^2$ with $\sigma(e^+e^-\rightarrow \Xi_{cc}^{(+)}X)$ of 500 fb and both $B(\Xi_{cc}^{(+)}\rightarrow \Xi_{cc}^{0}\pi^+(\pi^-\pi^+))$ and $B(\Xi_{cc}^{0}\rightarrow \Xi^-\pi^+)$ of 5%. The relative yields of signal MC for each decay mode are based on $N_{\Xi_{cc}}^{i}$.

A simultaneous UML fit, with the relative $\Xi_{cc}$ yields constrained as discussed earlier, is applied to evaluate the statistical significance of the $\Xi_{cc}$. The signal PDF is described with MC events generated for each decay mode and with the $\Xi_{cc}$ mass generated in the search region with a 1 MeV/$c^2$ step. The mass resolution is 2.7-4.2 MeV/$c^2$, depending on the mass of the $\Xi_{cc}$. The background PDF is modeled as a third-order polynomial. The highest significance is 3.2$\sigma$ for the mass around 3.553 GeV/$c^2$ in the $M(\Xi^0_c\pi^+)$. We perform a pseudo-experiment test to evaluate the probability of observing a peak with such a statistical significance. A smooth mass distribution based on data is generated and the significance is evaluated in the entire search region. The probability to observe a peak with a significance higher than 3.2$\sigma$ in one pseudo-experiment is 26%. Therefore, the statistical significance of 3.2$\sigma$ is insufficient to claim evidence of the $\Xi_{cc}$.

The 95% C.L. upper limit for the product of the cross section and branching fractions produced with 0.45 < $x_p$ < 1.0 condition,

$$\sigma_B^2 \equiv \sigma(e^+e^-\rightarrow \Xi_{cc}^{(+)}X) \times B(\Xi_{cc}^{(+)}\rightarrow \Xi_{cc}^{0}\pi^+(\pi^-\pi^+)) \times B(\Xi_{cc}^{0}\rightarrow \Xi^-\pi^+)$$

is evaluated with the same method as in section III. B

In addition to the sources from the study with the $\Lambda^+$, two others are included here. The systematic uncertainty from the $\Lambda$ reconstruction efficiency is estimated to be 3% using the yield of the $B^+\rightarrow \Lambda\Lambda K^+$ with and without the requirement using decay vertex information. The systematic uncertainties related to $N_{\Xi_{cc}(2645)^+}$ are taken from their statistical errors. The systematic uncertainties are summarized in the fourth column in Table IV.
We have presented a search for doubly-charmed baryons and a study of the charmed strange baryons (b) Ξ_{cc}^{++} and a study of the charmed strange baryons (c) Ξ_{cc}. The mass and width are measured to be 3058.1 ± 2.1 MeV/c^2 and 9.7 ± 3.4 (stat) ± 3.3 (sys) MeV/c^2, respectively. We do not observe any significant Ξ_{cc} signal corresponding to the Ξ_{cc}. These values are comparable to some of the theoretical predictions [28, 29].

If we assume $B(Ξ_{cc}^{++} → Λ_{c}^{+} K^{-} π^{+}(π^{+}))$, $B(Ξ_{cc}^{0} → Λ_{c}^{+} K^{-} π^{+}(π^{+}))$ and $B(Ξ_{cc}^{0} → Ξ_{cc}^{0} π^{+}(π^{+}))$ for the decay mode with the Λ_{c}^{+} and 30–140 fb (Ξ_{cc}^{0}) and 33–160 fb (Ξ_{cc}^{0}) for the decay mode with the Ξ_{cc}^{0}. We should multiply our result by two as written in section III. For the final states with Λ_{c}^{+}, their upper limit is for the product of cross section, $B(Ξ_{cc}^{++} → Λ_{c}^{+} K^{-} π^{+}(π^{+}))$ and $B(Λ_{c}^{+} → pK^{-} π^{+})$. The values presented in Ref. [34] are the highest upper limits in the search region, which can be compared with our highest values. After taking into account these points, we find our limits represent improvements by about a factor two for the final states with Λ_{c}^{+} and a factor of four for the final states with Ξ_{cc}^{0}.

We have searched for the Ξ_{cc} in the Λ_{c}^{+} K^{−} π^{+}(π^{+}) and Ξ_{cc}^{0} π^{+}(π^{+}) final states. The Λ_{c}^{+} is reconstructed from the pK^{−} π^{+} and pK_{S}^{0} decay modes. We do not find any significant Ξ_{cc} signal and set a 95% C.L. upper limit on $σ(e^{+}e^{-} → Ξ_{cc}^{++}(X)) \times B(Ξ_{cc}^{++} → Λ_{c}^{+} K^{−} π^{+}(π^{+}))$ with the scaled momentum 0.5 < x_{p} < 1.0: 4.1–25.0 fb for Ξ_{cc}^{++}, 2.5–26.5 fb for Ξ_{cc}^{0}. We also search for the Ξ_{cc} in the Ξ_{cc}^{0} π^{+}(π^{+}) final state. The Ξ_{cc}^{0} is reconstructed from the Ξ_{cc}^{−} π^{+}, Λ_{c}^{−} K^{+} π^{+}, and pK_{S}^{0} π^{−} decay modes. We do not find any significant Ξ_{cc} signal and set a 95% C.L. upper limit on $σ(e^{+}e^{-} → Ξ_{cc}^{++}(X)) \times B(Ξ_{cc}^{++} → Ξ_{cc}^{0} π^{+}(π^{+}))$ with the scaled momentum 0.45 < x_{p} < 1.0: 0.076–0.35 fb for the Ξ_{cc}^{++} and 0.082–0.40 fb for the Ξ_{cc}^{0}. When we compare these values with the measurements by BaBar, we should note several things.
FIG. 6: (a)-(c): $M(\Xi^0 c\pi^+)$ distribution in the $\Xi^+_cc$ search region for $\Xi^0 \rightarrow (a)$ $\Xi^-\pi^+$, (b) $\Lambda K^-\pi^+$, (c) $pK^-K^-\pi^+$. The vertical error bars are from data. The dashed histograms are from signal MC. (d): 95% C.L. upper limit of the $\sigma_{B2}$ for $\Xi^+_cc$ as a function of the mass with a 1 MeV/$c^2$ step.

(Keaky Collaboration)
We report results of a study of doubly charmed baryons and charmed strange baryons. The analysis is performed using a 980 fb$^{-1}$ data sample collected with the Belle detector at the KEKB asymmetric-energy $e^+e^-$ collider. We search for doubly charmed baryons $\Xi_{cc}^{+(+)}$ with the $\Lambda_c^+K^-\pi^+\pi^+$ and $\Xi^+\pi^+(\pi^+)$ final states. No significant signal is observed. We also search for two excited charmed strange baryons, $\Xi_c(3055)^+$ and $\Xi_c(3123)^+$ with the $\Sigma_{c}^{++}(2455)K^-$ and $\Sigma_{c}^{+}(2520)K^-$ final states. The $\Xi_c(3055)^+$ signal is observed with a significance of 6.6 standard deviations including systematic uncertainty, while no signature of the $\Xi_c(3123)^+$ is seen. We also study properties of the $\Xi_c(2645)^+$ and measure a width of $2.6 \pm 0.2$ (stat) $\pm 0.4$ (syst) MeV/$c^2$, which is the first significant determination.

I. INTRODUCTION

In recent years, there has been significant progress in charmed baryon spectroscopy, mainly by the Belle and BaBar experiments [1–8]. In particular, all the ground states of the single-charmed baryons predicted by the constituent quark model and several excited states have
However, there are no experimentally established doubly-charmed baryons. The lightest doubly-charmed baryon contains two charm quarks and one up or down quark (Ξ_{cc}^0 = ccd, Ξ_{cc}^{+} = ccu), and the spin-parity of the ground state is expected to be \( ^3S_1 \). The mass of the Ξ_{cc} has been extensively studied theoretically, and the prediction of the quark model ranges from 3.48 GeV/c^2 to 3.74 GeV/c^2 [10–22], whereas the mass predicted by lattice QCD ranges from 3.51 GeV/c^2 to 3.67 GeV/c^2 [23–27]. The cross sections of the Ξ_{cc} production in the process \( e^+e^- \rightarrow Ξ_{cc}X \) at \( \sqrt{s} = 10.58 \) GeV, where X denotes the remaining particles produced in the fragmentation, is predicted to be 70 fb in Ref. [28] and 230 fb in Ref. [29]. The cross section of the pair production of the cc and \( \bar{c}\bar{c} \) diquarks is predicted to be \( 7 \) fb [30].

In this paper, we report on an improved search for \( \Xi_{cc}^0 \) in the weak decays to the \( Λ^0 \) and \( Ξ_{cc}^{+} \) final states, and the measurement of the width of the \( Ξ_{cc}^{+}(2645) \). Currently, only the upper limit of 3.1 MeV/c^2 exists for its width [36]. In this paper, we also report on a search for the \( Ξ_{cc}^{0}(3055)^+ \) and \( Ξ_{cc}(3123)^+ \) in the \( Λ^0 K^+ \) final state, and the measurement of the width of the \( Ξ_{cc}^{+}(2645) \).

The remaining sections of the paper are organized as follows. In section II, the data samples and the Belle detector are described. In section III, a study of the final states with \( Λ^+ \), i.e., the \( Ξ_{cc} \) search and the \( Ξ_{cc}^{0}(3055)^+ \) and \( Ξ_{cc}(3123)^+ \) search, are reported. In section IV, a study of the final state with \( Ξ_{cc}^0 \), i.e., the \( Ξ_{cc} \) search and measurement of the width of the \( Ξ_{cc}^{+}(2645) \), are described. Finally, conclusions are given in section V.

II. DATA SAMPLES AND THE BELLE DETECTOR

We use a data sample with a total integrated luminosity of 980 fb\(^{-1} \) recorded with the Belle detector at the KEKB asymmetric-energy \( e^+e^- \) collider [37]. The data samples with different beam energies at or near the \( \Upsilon(1S) \) to \( \Upsilon(5S) \) are combined in this study. The beam energies and integrated luminosities are summarized in Table I. The luminosity-weighted average of \( \sqrt{s} \) is 10.59 GeV.

The Belle detector is a large-solid-angle magnetic spectrometer that consists of a silicon vertex detector (SVD), a 50-layer central drift chamber (CDC), an array of aerogel threshold Cherenkov counters (ACC), a barrel-like arrangement of time-of-flight scintillation counters (TOF), and an electromagnetic calorimeter comprised of CsI(Tl) crystals (ECL) located inside a superconducting solenoid coil that provides a 1.5 T magnetic field. An iron flux return located outside of the coil is instrumented to detect \( K^0_L \) mesons and to identify muons (KLM). The detector is described in detail elsewhere [38]. Two inner detector configurations were used. A 2.0 cm radius beam pipe and a 3-layer silicon vertex detector were used for the first sample of 156 fb\(^{-1} \), while a 1.5 cm radius beam pipe, a 4-layer silicon detector and a small-cell inner drift chamber were used to record the remaining 824 fb\(^{-1} \) [39].

The selection of charged hadrons is based on information from the tracking system (SVD and CDC) and the hadron identification system (CDC, ACC, and TOF). The charged proton, kaon, and pion that is not associated with long-lived particles like \( K^0_L \) is required to have a point of closest approach to the interaction point that is within 0.2 cm in the transverse (\( r-\phi \)) direction and within 2 cm along the z-axis. (The \( z \)-axis is opposite the positron beam direction.) For each track, the likelihood values \( L_p, L_K, L_{\pi} \) are provided for the assumption of proton, kaon and pion, respectively, from the hadron identification system, based on the ionization energy loss in the CDC, the number of detected Cherenkov photons in the ACC, and the time of flight measured by the TOF. The likelihood ratio is de-
In this section, the analysis using the final states with the $\Lambda_{cc}^+$ baryon is described. Reconstruction of the $\Lambda_{cc}^+$ candidate is explained first, followed by the description of the $\Xi_{cc}^+(\mp)$ search in its decay into $\Lambda_{cc}^+ K^- \pi^+ (\pi^+)$ and the study of two charmed strange baryons, $\Xi_c (3055)^+$ and $\Xi_c (3123)^+$. Throughout this paper, the selection criteria are determined to maximize the figure of merit (FOM), defined as $\epsilon / \sqrt{N_{\text{bg}}}$, where $\epsilon$ is the $\Xi_{cc}$ efficiency for the selection criteria and $N_{\text{bg}}$ is the number of background events under the signal peak except for the scaled momentum selection for $\Xi_c (3055)^+$ and $\Xi_c (3123)^+$ search, which followed BaBar’s analysis. The distribution of background events is estimated based on data. When the selection criteria are determined, we hide the possible signal peak by smearing invariant mass of the $\Xi_{cc}$ candidates event by event with a Gaussian having a 50 MeV/$c^2$ width in order to avoid any biases.

### A. Reconstruction of the $\Lambda_{cc}^+$

The $\Lambda_{cc}^+$ candidates are reconstructed in the $pK^- \pi^+$ and $pK_S^0$ decay modes [45]. The $K_S^0$ candidate is reconstructed from its decay into $\pi^+ \pi^-$. A pair of oppositely charged pions that have an invariant mass within 8 MeV/$c^2$ of the nominal $K_S^0$ mass, which corresponds to approximately 3.5$\sigma$ of the mass resolution, is used. Two pion tracks are fitted to a common vertex. The result of the fit is used to suppress misreconstructed $K_S^0$ candidates and to perform further vertex fit of the $\Lambda_{cc}^+ \rightarrow pK_S^0$. The vertex of the two pions for the $K_S^0$ is required to be displaced from the interaction point (IP) in the direction of the pion pair momentum [46]. The daughters of the $\Lambda_{cc}^+$ are fitted to a common vertex; the invariant mass of the daughters must be within 5 (6) MeV/$c^2$, or 1.5$\sigma$, nominal $\Lambda_{cc}^+$ mass for the $pK^- \pi^+$ ($pK_S^0$) decay mode. The $\chi^2$ value of the common vertex fit of the $\Lambda_{cc}^+$ is required to be less than 50. For the remaining candidate, a mass constraint fit to the $\Lambda_{cc}^+$ mass is performed to improve the momentum resolution. As the signal-to-background ratio for the $\Lambda_{cc}^+$ candidates is similar for the $pK^- \pi^+$ and $pK_S^0$ decay modes, they are combined in the following analysis. By including the $pK_S^0$ mode in addition to the $pK^- \pi^+$ mode, the yield of the $\Lambda_{cc}^+$ is increased by about 20%.

### B. Search for doubly charmed baryons in $\Lambda_{cc}^+ K^- \pi^+ (\pi^+)$

We search for the $\Xi_{cc}^+(\mp)$ in its decay into $\Lambda_{cc}^+ K^- \pi^+ (\pi^+)$ in the mass range of 3.2-4.0 GeV/$c^2$. The expected mass resolution of the $\Xi_{cc}$ estimated from MC is 2.0-3.5 MeV/$c^2$, depending on the mass of the $\Xi_{cc}$ (degrading with increasing mass). In order to reduce the combinatorial background, a selection on the scaled momentum $x_p = p^* / \sqrt{s/4 - m^2}$ is used, where $p^*$ is the CM momentum of a $\Xi_{cc}$ candidate and $s$ is CM energy squared and $m$ is mass of the $\Xi_{cc}$ candidate. As there is no measurement of the $x_p$ spectrum for the $\Xi_{cc}$ production, we assume it to be the same as that of the $\Lambda_{cc}^+$, which has been precisely measured [47]. The $x_p$ spectrum is represented by a smooth polynomial function and is used to generate a MC sample for the $\Xi_{cc}$ signal. Decays of the $\Xi_{cc}$ and $\Lambda_{cc}^+$ are generated according to the available phase space distribution. The number of background events as a function of the $x_p$ cut is estimated based on smeared data. The FOM as a function of the $x_p$ cut is surveyed in the search region. The optimization procedure yields $0.5 < x_p < 1.0$ regardless of the $\Xi_{cc}$ mass. To check the validity of our analysis, we independently examine the $x_p$ spectrum of the $\Lambda_{cc}^+$ and confirm that it is consistent with that presented in Ref. [47].

Figure 1 (a) and (b) show the $M(\Lambda_{cc}^+ K^- \pi^+)$ and $M(\Lambda_{cc}^+ K^- \pi^+ \pi^+)$ distributions, respectively, for data after all the event selections applied. No significant signal is seen in the data for either $\Xi_{cc}^+$ or $\Xi_{cc}^{++}$. The statistical significance for a given mass is evaluated with an unbinned extended maximum likelihood (UML) fit. The probability density function (PDF) for the signal is described with signal MC generated for each given $\Xi_{cc}$ mass, whereas a third-order polynomial function is used as the background PDF. The statistical significance is defined as $\sqrt{2 \ln (L_0 / L)}$, where $L_0$ is the likelihood for the fit without the signal component and $L$ is the likelihood for the fit with the signal component included. The significance is evaluated for the $\Xi_{cc}$ mass scanned with a 1 MeV/$c^2$ step in the search region. None of the mass points give a significance exceeding the 3$\sigma$ level.
The 95% confidence level (C.L.) upper limit for the product of the cross section and branching fraction to the \( \Lambda_c K^- \pi^+ (\pi^+) \) state produced with the \( 0.5 < x_p < 1.0 \) condition, 
\[
\sigma_B \equiv \sigma(e^+ e^- \rightarrow \Xi_{cc}^{+}(X)) \times B(\Xi_{cc}^{+}(\pi^+) \rightarrow \Lambda_c^+ K^- \pi^+ (\pi^+))
\]
\[
= \frac{2L B_{pK^- \pi^+} (\epsilon_{pK^- \pi^+} B_{pK^-} / B_{pK^- \pi^+})}{N_{\text{sig}}}
\]
is evaluated. Here, \( L \) is the total integrated luminosity, \( N_{\text{sig}} \) is the \( \Xi_{cc} \) signal yield, \( B_{pK^- \pi^+} \) is the branching fraction of the \( \Lambda_c^+ \rightarrow pK^- \pi^+ \) (which amounts to 0.050 \( \pm 0.013 \)), \( B_{pK^-} \) is the branching fraction of \( \Lambda_c^+ \rightarrow pK^- \pi^+ \), measured relative to the \( pK^- \pi^+ \) mode \( (B_{pK^-}/B_{pK^- \pi^+} = 0.24 \pm 0.02) \), and \( \epsilon_{pK^- \pi^+} \) is the reconstruction efficiency for the \( \Lambda_c^+ \rightarrow pK^- \pi^+ (\Lambda_c^+ \rightarrow pK^0_S) \) decay mode evaluated as a function of the \( \Xi_{cc} \) mass. The efficiencies for the \( \Xi_{cc}^{+}(\pi^+) \) as a function of their masses are shown in Fig. 2. The factor of two in the denominator comes from inclusion of the charge-conjugate mode. By including this factor, our measurement can be compared with the theoretical predictions [28, 29]; while to compare with the prediction in Ref. [30], it is necessary to multiply our \( \sigma_B \) measurement by 2 because they predicted the cross section of the pair production of the \( cc \) and \( \bar{c}\bar{c} \) diquarks. In BaBar’s measurement [34], they do not introduce the factor of two \( (i.e., \) they report an upper limit for the sum of the \( \sigma(e^+ e^- \rightarrow \Xi_{cc}^{+}(X)) \) and its charge-conjugate mode). Therefore, our measurement should be doubled when comparing with BaBar’s result. We note that the cross section reported here and elsewhere in this paper is a visible cross section \( (i.e., \) a radiative correction is not applied.

The upper limit is evaluated following the Bayesian approach. First, we scan the likelihood profile by determining the likelihood values as a function of the \( \sigma_B \) \( (\mathcal{L}(\sigma_B)) \), varying \( N_{\text{sig}} \) from zero up to the \( N_{\text{sig}} \) value for which the likelihood drops to zero. Then, \( \mathcal{L}(\sigma_B) \) is convolved with a Gaussian whose width equals the systematic uncertainties of \( \sigma_B \). The \( \sigma_B \) value for which the integral \( (\text{starting from } \sigma_B = 0) \) becomes 95% of the entire area is regarded
as the 95% C.L. upper limit.

We consider the following systematic uncertainties in the $\Xi_{cc}$ search. The systematic uncertainty due to the efficiency of pion and kaon identification is estimated from the ratio of the yield of the $D^{*+} \rightarrow D^0 \pi^+$, $D^0 \rightarrow K^+ \pi^+$ with and without the pion/kaon identification requirements for data and MC. The difference of the ratio between data and MC is corrected and the statistical error of the ratio is regarded as the systematic uncertainty. The systematic uncertainty due to the efficiency of proton identification is estimated using the ratio of the yield of the $\Lambda \rightarrow p\pi^-$ with and without the proton identification requirement. The difference of the ratio between data and MC is corrected and the statistical error of the ratio is regarded as the systematic uncertainty. The systematic uncertainty due to the charged track reconstruction efficiency is estimated using the decay chain $D^{*+} \rightarrow \pi^+ D^0$, $D^0 \rightarrow \pi^+ \pi^- K^0_S$, and $K^0_S \rightarrow \pi^+ \pi^-$, where $K^0_S \rightarrow \pi^+ \pi^-$ is either partially or fully reconstructed. The ratio of the yields for partially and fully reconstructed signals in data and MC is compared, and the difference is taken as the systematic uncertainty. This amounts to 0.35% per track. The systematic uncertainty of the total integrated luminosity is 1.4%. To check the systematic error due to the signal PDF, we compare the mass resolution of the $\Lambda^+_c$ in data and MC. We find that the resolution for data is 5% larger than in MC. To monitor the effect of this discrepancy, we perform a pseudo-experiment test in which we extract the signal yield with correct PDF and one that is narrower by 5%. The largest difference of 3% measured in this test is regarded as the systematic uncertainty. The systematic uncertainty related to the $\Lambda^+_c$ branching fraction is propagated from the errors taken from the PDG [9]. To estimate the systematic uncertainty of the reconstruction efficiency due to the possible difference of $x_p$ spectrum between our assumption (the same as that of $\Lambda^+_c$) and actual one, we examine the $x_p$ dependence of the reconstruction efficiency. The root mean square of the reconstruction efficiency in the region of $0.5 < x_p < 1.0$ is regarded as the systematic uncertainty. The results of the systematic uncertainty for the measurement of the $\sigma_B$ are enumerated in the first and second columns of Table II.

Figures 1 (c) and (d) show the 95% C.L. upper limit on $\sigma_B$ for $\Xi^+_c$ and $\Xi^{++}_{cc}$, respectively, as a function of the mass with a 1 MeV/$c^2$ step. The upper limit is in the range of 4.1–25.0 fb for the $\Xi^{++}_{cc}$ and 2.5–26.5 fb for the $\Xi^+_c$.

C. Search for the $\Xi^+_c(3055)$ and $\Xi^+_c(3123)$

In this section, a search for the $\Xi^+_c(3055)$ and $\Xi^+_c(3123)$ is described. Here, we require $x_p$ to be greater than 0.7. In the analysis by BaBar [6], they required $p^*(\Lambda^+_c K^- \pi^+) > 2.9$ GeV/$c$, which is similar to our $x_p$ cut as illustrated by the $p^*(\Lambda^+_c K^- \pi^+)$ distribution, with the $x_p$ cut and 2.9 GeV/$c^2 < M(\Lambda^+_c K^- \pi^+) < 3.2$ GeV/$c^2$ required as shown in Fig. 3 (a). Figure 3 (b) shows the $M(\Lambda^+_c \pi^+)$ distribution, where contributions from the $\Sigma_c(2520)^{++}$ and the $\Sigma_c(2520)^{++}$ baryons are clearly visible. We select the $\Sigma_c(2455)^{++}$ ($\Sigma_c(2520)^{++}$) region by requiring $|M(\Lambda^+_c \pi^+) - m_{\Sigma_c^{++}}| < 5$ (18) MeV/$c^2$, where $m_{\Sigma_c^{++}}$ is the nominal mass of the $\Sigma_c(2455)^{++}$ or $\Sigma_c(2520)^{++}$.

Figure 3 (c) shows the $M(\Lambda^+_c K^- \pi^+)$ distribution for the $\Sigma_c(2520)^{++}$ signal region together with the same plot for the $\Sigma_c(2455)^{++}$ sideband region, defined as $|M(\Lambda^+_c \pi^+) - (m_{\Sigma_c^{(2455)^{++}}} \pm 15 \text{ MeV}/c^2)| < 5 \text{ MeV}/c^2$. Clear peaks corresponding to the $\Xi_c(2950)^+$, $\Xi_c(3055)^+$ and $\Xi_c(3080)^+$ are seen. To obtain the statistical significance of the $\Xi_c(3055)^+$, an UML fit is applied. PDFs for the $\Xi^{++}_c$ components are represented by a Breit-Wigner line-shape convolved with a Gaussian to account for the invariant-mass resolution ($\sigma_{res}$). Using the signal MC events, we estimate $\sigma_{res}$ to vary from 1.2 to 1.8 MeV/$c^2$, depending on the masses of the $\Xi^{++}_c$ states. The width and mean of the Breit-Wigner functions are treated as free parameters. The background PDF, $f_1(x)$, is modeled with a threshold function:

$$f_1(x) = 1 - \exp((-x - x_0)/\delta_m)(x/x_0)^a + b(x/x_0 - 1) \quad (x > x_0)$$

$$f_1(x) = 0 \quad (x < x_0),$$

where $a$, $b$, $x_0$, and $\delta_m$ are free parameters in the fit.

The fit result is shown in Fig. 3 (c). To estimate the statistical significance of the $\Xi_c(3055)^+$, we compare the likelihood values for the fits with and without the $\Xi_c(3055)^+$ component. The obtained $-2 \ln (L_0/L)$ value is 54.7. By taking into account the change of the number of degrees of freedom ($ndf$) by the inclusion of the $\Xi_c(3055)^+$ component, the statistical significance of the $\Xi_c(3055)^+$ becomes 6.8$\sigma$. The $\chi^2/ndf$ of the fit with the $\Xi_c(3055)^+$ component, for the binning of Fig. 3 (c), is 54.8/61.

Figure 3 (d) shows the $M(\Lambda^+_c K^- \pi^+)$ distribution for the $\Sigma_c(2520)^{++}$ selected region together with the same plot for the $\Sigma_c(2520)^{++}$ sideband region, defined as $|M(\Lambda^+_c \pi^+) - (m_{\Sigma_c^{(2520)^{++}}} \pm 27 \text{ MeV}/c^2)| < 12 \text{ MeV}/c^2$. A clear peak corresponding to the $\Xi_c(3080)^+$ is seen, while no peak structure is seen in the mass near 3.123 GeV/$c^2$. An UML fit is applied to extract the signal yield. Again, the $\Xi^{++}_c$ components are represented by a Breit-Wigner function convolved with a Gaussian. For the $\Xi_c(3080)^+$ component, the mass and width of the Breit-Wigner are treated as free parameters; while for the $\Xi_c(3123)^{++}$ component, the mass and width are fixed to the values obtained in Ref.[6]. The background shape, $f_2(x)$, is assumed to be:

$$f_2(x) = (1 - \exp((-x - x_0)/\delta_m))(x/x_0)^a + b(x/x_0 - 1) + c((x/x_0)^2 - 1) \quad (x > x_0)$$

$$f_2(x) = 0 \quad (x < x_0),$$

where $a$, $b$, $x_0$, and $\delta_m$ are free parameters in the fit.
where \(a, b, c, x_0,\) and \(\delta_m\) are fit parameters. The \(\chi^2/ndf\) of the fit with the \(\Xi_c(3123)^+\) component for the binning of Fig. 3 (d) is 28.6/42. The yield of the \(\Xi_c(3123)^+\) is \(8 \pm 22\) events, which is consistent with zero. Hence, a 95% C.L. upper limit for the production cross section is evaluated with the method described in the previous section. To directly compare with the BaBar result in Ref. [6], the upper limit for the product of the cross section and branching fraction of \(\Lambda_c^+\) produced with \(x_p > 0.7\) condition,

\[
\sigma_{BA^+} = \sigma(e^+e^- \rightarrow \Xi_c(3123)^+X) \times B(\Lambda_c^+ \rightarrow pK^\pi^+) = 2L(\epsilon_{pK^\pi^+} \times B_{pK^\pi^+}/B_{pK^\pi^+})
\]

is evaluated. As in Ref. [6], we assume \(B(\Xi_c(3123)^+ \rightarrow \Sigma_c(2520)^+K^-)\) is equal to 1.

To take the uncertainty of the \(\Xi_c(3123)^+\) mass and width from Ref. [6] into account, we perform a pseudo-experiment test. The background and \(\Xi_c(3080)^+\) contributions are generated with statistics similar to data and based on the fit result. The \(\Xi_c(3123)^+\) component is generated with mass and width changed by \(\pm 1\sigma,\) corresponding to their measured uncertainties \(3122.9 \pm 1.3 \pm 0.4\) MeV/c\(^2\) for the mass and \(4.4 \pm 3.4 \pm 1.7\) MeV/c\(^2\) for the width). The yield of \(\Xi_c(3123)^+\) is extracted by fitting pseudo-experiment data with the procedure used for data. The ratio of the generated and extracted yield is regarded as a systematic uncertainty. Because the error of the width is relatively large, its systematic uncertainty contribution is dominant (28%). All of the systematic errors are summarized in the third column of Table II. The 95% C.L. upper limit on \(\sigma_{BA^+}\) is 0.17 fb. As in the case of the \(\Xi_{cc}\) cross section, the measurement in Ref. [6] does not introduce a factor of two for the \(\sigma_{BA^+}\) calculation. Therefore, we should double our measurement, which results in 0.34 fb, when comparing with BaBar’s result. The value is much smaller than that quoted in Ref. [6] \((1.6 \pm 0.6 \pm 0.2\) fb).

The systematic uncertainties of the masses and widths of the \(\Xi_{c}^{++}\) and stability of the statistical significance of the \(\Xi_c(3055)^+\) are studied by the following fitting configurations. The systematic uncertainties due to the signal PDF are studied by varying \(\sigma_{res}\) by 5%. The systematic uncertainties due to possible interference between the \(\Xi_c(3055)^+\) and \(\Xi_c(3080)^+\) are studied by fitting the distribution with an additional phase parameter between the two Breit-Wigner amplitudes. The systematic uncertainty due to the background shape is studied by fitting the mass spectra with a second-order polynomial as a background PDF in the range of 3.005-3.200 GeV/c\(^2\). In none of these fitting configurations does the statistical significance of the \(\Xi_c(3055)^+\) fall below 6.6\(\sigma\). We apply cut conditions of \(x_p > 0.6\) and \(x_p > 0.8\) instead of \(x_p > 0.7\) and re-extract the masses and widths of the

---

total: 26.5 26.6 28.2 9.2 9.2
required to be within 4 MeV/\textit{c} of the vector between the IP and the Ξ.

The daughter particles of the Ξ decay modes, respectively, which correspond to approximately 1.0 MeV/\textit{c} for the Λ and π− tracks for Ξ− candidates are fitted to a common vertex. The fitting result is used to clean up the Ξ− candidates and in the common vertex fit for the Ξ→Λπ− or Ξ→ΛK−π+. The closest distance of the Λ and π− along the z-direction is required to be less than 3 mm. We require \cos{\theta} > 0.95, where \theta is the angle between the momentum vector of the Ξ− and the vector between the IP and the Ξ− decay vertex. The χ² of the common-vertex fit of the Λπ− is required to be less than 50. The invariant mass of a Ξ− candidate is required to be within 4 MeV/\textit{c}² of the nominal Ξ− mass, which corresponds to approximately 3 \sigma of the mass resolution. The daughter particles of the Ξ∗ are fitted to a common vertex. The Ξ∗ candidates are selected by requiring invariant masses of the daughter particles with common vertex fit to be within 12, 7 and 7 MeV/\textit{c}² of the nominal Ξ∗ mass for the Ξ∗→Σ+π+, ΛK−π+ and pK−K−π+ decay modes, respectively, which correspond to approximately 1.5 \sigma of the mass resolution. The χ² value of the common vertex fit for the Ξ∗ is required to be less than 50. The mass constraint fit to the Ξ∗ mass is performed.

We optimize the selection criteria for \textit{x}_p in the Ξ∗=(Σ+π+) system with the method described in III B, again assuming that the \textit{x}_p spectrum for the Ξ∗ is the same as that for the Λ. We require 0.45 < \textit{x}_p < 1.0 independent of the Ξ∗ mass and the Ξ decay mode. The same cut is applied for the analysis of the Ξ(2645)+.

### IV. FINAL STATE WITH Ξ∗

In this section, the analysis of the final state with the Ξ∗ is described. The reconstruction of the Ξ∗ is presented first, followed by the analysis of the Ξ(2645)+. Finally, a search for Ξ∗(Σ+π+) decaying into the Ξ(2645)+ (Σ+π+) final state is described.

#### A. Reconstruction of Ξ∗

The Ξ∗ is reconstructed in three decay modes: Ξ−π+, ΛK−π+ and pK−K−π+. The Λ is reconstructed from its decay into ppπ−. The proton and π− tracks for Λ candidates are fitted to a common vertex. The fitting result is used to suppress misreconstructed Λ candidates and to perform the subsequent vertex fit for the Ξ−→Λπ− or Ξ→ΛK−π+. The invariant mass of the Λ candidate is required to be within 3 MeV/\textit{c}² of the nominal Λ mass, which corresponds to approximately 3 \sigma of the mass resolution. The selection based on their decay vertex information is also applied [48]. The Ξ− is reconstructed from its decay into Λπ−. The Λ and π− tracks for Ξ− candidates are fitted to a common vertex. The fitting result is used to clean up the Ξ− candidates and in the common vertex fit for the Ξ→Ξ∗π+. The closest distance of the Λ and π− along the z-direction is required to be less than 3 mm. We require \cos{\theta} > 0.95, where \theta is the angle between the momentum vector of the Ξ− and the vector between the IP and the Ξ− decay vertex. The χ² of the common-vertex fit of the Λπ− is required to be less than 50. The invariant mass of a Ξ− candidate is required to be within 4 MeV/\textit{c}² of the nominal Ξ− mass, which corresponds to approximately 3 \sigma of the mass resolution. The daughter particles of the Ξ∗ are fitted to a common vertex. The Ξ∗ candidates are selected by requiring invariant masses of the daughter particles with common vertex fit to be within 12, 7 and 7 MeV/\textit{c}² of the nominal Ξ∗ mass for the Ξ∗→Σ+π+, ΛK−π+ and pK−K−π+ decay modes, respectively, which correspond to approximately 1.5 \sigma of the mass resolution. The χ² value of the common vertex fit for the Ξ∗ is required to be less than 50. The mass constraint fit to the Ξ∗ mass is performed.

We optimize the selection criteria for \textit{x}_p in the Ξ∗=(Σ+π+) system with the method described in III B, again assuming that the \textit{x}_p spectrum for the Ξ∗ is the same as that for the Λ. We require 0.45 < \textit{x}_p < 1.0 independent of the Ξ∗ mass and the Ξ decay mode. The same cut is applied for the analysis of the Ξ(2645)+.

#### B. Study of the Ξ∗(2645)

Unlike the Λ study, the signal-to-background ratio of the Ξ∗ largely depends on the decay modes. Therefore, to improve our sensitivity for the Ξcc, we perform a simultaneous fit to the mass spectra for the three Ξ∗ decays with fixed relative signal ratios. We use the relative yields of the Ξ∗(2645)+→Ξ0π+ measured for the Ξ∗ decay modes to estimate a relative signal yield of the Ξcc. The relative signal yields of the Ξcc (N^∗_{Ξcc}) in a given Ξ∗ decay channel can be written as

\[ N^∗_{Ξcc} = N^∗_{Ξ(2645)+} \frac{\epsilon^∗_{Ξ^∗}}{\epsilon_{Ξ(2645)+}}, \]

where N^∗_{Ξ(2645)+} is the Ξ∗(2645)+ yield, \epsilon^∗_{Ξ^∗} is the reconstruction efficiency of the Ξcc, and \epsilon_{Ξ(2645)+} is the reconstruction efficiency of the Ξ(2645)+. Both efficiencies include the secondary branching fractions for Λ→π− of (63.9±0.5)% and Ξ→Λπ− of (99.887±0.035)%.

The index i denotes the decay mode of the Ξ∗.

Figure 4 shows the M(Ξ∗(Σ+π+)) distribution for each Ξ∗ decay mode below the Ξ∗ search region. Clear peaks corresponding to the Ξ∗(2645)+ are seen in all decay modes. The bump structures near 2.68 GeV/\textit{c}² originate from the process Ξ∗(2790)→Ξ0π+→Ξ0γπ with a γ missing in the reconstruction. The simultaneous UML fit is applied to extract the relative yields and the width of the Ξ∗(2645)+. The Ξ∗(2645)+ signal is represented by a Breit-Wigner function convolved with a Gaussian whose width corresponds to the mass resolution \sigma_{res}. The value of \sigma_{res} is 1.05 MeV/\textit{c}², independent of the decay modes of the Ξ∗. The PDF of the Ξ∗(2790)+ reflection is modeled using MC, \textit{f}_2(x) in Eq. 2 is used as the background PDF for the Ξ∗(2645)+→Ξ∗(Σ+π+) decay mode whereas \textit{f}_1(x) in Eq. 1 is used for the Ξ∗(2645)+→ΛK−π+ and Ξ∗(2645)+→pK−K−π+ decay modes. The width and mass of the Ξ∗(2645)+ are constrained to be the same for the three decay modes. The yield of the Ξ∗(2645)+ is 1298±51, 1444±58 and 974±47 for the Ξ∗(Σ+π+), ΛK−π+ and pK−K−π+ decay modes, respectively. The mass and width are obtained to be 2645.4±0.1 MeV/\textit{c}² and 2.6±0.2 MeV/\textit{c}², respectively. The χ²/ndf of the fit for the binning in Fig. 4 is 296/276.

To check the consistency of the width measurement between the Ξ∗ decay modes, we fit the three mass spectra separately. The measured widths are found to be consistent between the three decay modes: 2.9±0.3 MeV/\textit{c}², 2.6±0.3 MeV/\textit{c}² and 2.5±0.3 MeV/\textit{c}² for Ξ0→Ξ−π+, ΛK−π+ and pK−K−π+, respectively. The measured width is found to be consistent for the three decay modes. The systematic uncertainty of the width measurement due to the fit procedure is studied with
FIG. 3: (a) The $p^*(\Lambda^+ K^- \pi^+)$ distribution from data. (b) The $M(\Lambda^+ \pi^+)$ distribution. The vertical lines show the selected regions of the $\Sigma_c(2455)^{++}$ and $\Sigma_c(2520)^{++}$. (c) The $M(\Lambda^+ K^- \pi^+)$ distribution with $\Sigma_c(2455)^{++}$ selection. The dots with error bars show the distribution for the $\Sigma_c(2455)^{++}$ selected region whereas the rectangles show the distribution for the $\Sigma_c(2455)^{++}$ sideband region. The solid line shows the fit result. The dashed, dotted, and dash-dotted lines show the contributions from the background, $\Xi_c(3055)^+$, and $\Xi_c(2980)^+$ or $\Xi_c(3080)^+$, respectively. (d) The $M(\Lambda^+ K^- \pi^+)$ distribution with $\Sigma_c(2520)^{++}$ selection. The dots with error bars show the distribution for $\Sigma_c(2520)^{++}$ selected region whereas the rectangles show the distribution for the $\Sigma_c(2520)^{++}$ sideband region. The solid line shows the fit result. The dashed, dotted, and dash-dotted lines show the contributions from the background, $\Xi_c(3123)^+$, and $\Xi_c(3080)^+$, respectively.

FIG. 4: $M(\Xi^0 \pi^+)$ distributions below the $\Xi_{cc}$ search region for (a) $\Xi^0_c \rightarrow \Xi^- \pi^+$, (b) $\Xi^0_c \rightarrow \Lambda K^- \pi^+$, (c) $\Xi^0_c \rightarrow p K^- K^- \pi^+$. The solid lines show the fit result. The dashed, dotted, and dash-dotted lines show the contributions from background, $\Xi_c(2645)^+$, and $\Xi_c(2790)^+$, respectively.
TABLE III: The measured masses and widths of the three \( \Xi^{0}_{cc} \) states. The first error is statistical and second is systematic.

| Particle          | Mass (MeV/c^2) | Width (MeV/c^2) | Yield |
|-------------------|----------------|-----------------|-------|
| \( \Xi^{0}_{c}(2980)^{+} \) | 2974.9 ± 1.5 ± 2.1 | 14.8 ± 2.5 ± 4.1 | 244 ± 39 |
| \( \Xi^{0}_{c}(3055)^{+} \) | 3058.1 ± 1.0 ± 2.1 | 9.7 ± 3.4 ± 3.3 | 199 ± 46 |
| \( \Xi^{0}_{c}(3080)^{+}(\Sigma_{c}) \) | 3077.9 ± 0.4 ± 0.7 | 3.2 ± 1.3 ± 1.3 | 185 ± 31 |
| \( \Xi^{0}_{c}(3080)^{+}(\Sigma_{c}) \) | 3076.9 ± 0.3 ± 0.2 | 2.4 ± 0.9 ± 1.6 | 210 ± 30 |

pseudo-experiment events samples: the \( \Xi^{0}_{c}(2645)^{+} \) component is generated according to the signal MC sample with the natural width of 2.6 MeV/c^2 by signal MC, while contributions from background and \( \Xi^{0}_{c}(2790)^{+} \) reflection are generated based on the fit result with the real data. The statistics of the pseudo-experiment samples are the same as for those of data. The width of the \( \Xi^{0}_{c}(2645)^{+} \) is extracted from simultaneous fits to pseudo-experiment samples, and its mean value is obtained to be 2.75 ± 0.03 MeV/c^2, which is higher than the input value by 0.15 MeV/c^2. The difference is included as the systematic uncertainty from the fit procedure. The systematic uncertainty due to the background shape is studied by fitting the data with a second-order polynomial function for the alternative background shape. The fit region is restricted to 2.62-2.75 GeV/c^2. The width is obtained to be 2.9 ± 0.2 MeV/c^2, which is 0.3 MeV/c^2 higher than the default measurement. This deviation is included as a systematic uncertainty. To check the systematic uncertainty due to the mass resolution, we evaluate the ratio of the resolution of \( \Xi^{0}_{c} \) in the data and MC, \( \sigma_{\text{data}} / \sigma_{\text{MC}} \), where \( \sigma_{\text{data}} \) is the resolution of \( \Xi^{0}_{c} \) for data and \( \sigma_{\text{MC}} \) for MC. An additional cut of 2.64 GeV/c^2 < \( \Xi^{0}_{c} \) < 2.65 GeV/c^2 is applied to select the \( \Xi^{0}_{c}(2645)^{+} \) region only. \( \frac{\sigma_{\text{data}}}{\sigma_{\text{MC}}} \) is 0.96 ± 0.03, 1.03 ± 0.07 and 1.07 ± 0.03 for the \( \Xi^{0}_{c} \) and \( \Xi^{0}_{c} \) in the \( \Lambda K^{-} \) and \( pK^{-}K^{-} \) decay modes, respectively. We assign the systematic uncertainty conservatively by increasing the mass resolution by 7%, which is the largest deviation of the \( \frac{\sigma_{\text{data}}}{\sigma_{\text{MC}}} \) from unity, for all the decay modes. The resulting width is 2.5 ± 0.2 MeV/c^2. The difference of 0.1 MeV/c^2 with respect to the default measurement is included as a systematic uncertainty. We use alternative \( x_{p} \) range of 0.35 < \( x_{p} < 1.0 \) and 0.55 < \( x_{p} < 1.0 \) and extract the width of 2.6 ± 0.2 MeV/c^2 for the former case and 2.8 ± 0.2 MeV/c^2 for the latter. The largest difference of 0.2 MeV/c^2 with respect to the default measurement is included as a systematic uncertainty. By adding all the systematic uncertainties in quadrature, the total systematic uncertainty for the width measurement is estimated to be 0.4 MeV/c^2.

C. Search for doubly charmed baryons in the \( \Xi^{0}_{c}(2645)^{+}(\pi^{+}) \) final state

To obtain the relative yields of the \( \Xi^{0}_{cc} \), \( \epsilon_{\Xi^{0}_{cc}} \) and \( \epsilon_{\Xi^{0}_{c}(2645)^{+}} \) are evaluated using MC, and the efficiency \( \epsilon_{\Xi^{0}_{cc}} \) is obtained as a function of the \( \Xi^{0}_{cc} \) mass. \( \epsilon_{\Xi^{0}_{c}(2645)^{+}} \) are summarized in Table IV, while \( \epsilon_{\Xi^{0}_{cc}} \) as a function of \( \Xi^{0}_{cc} \) mass is shown in Fig. 5. As an example, the relative yield ratio of the \( \Xi^{0}_{cc} \) with a mass of 3.6 GeV/c^2 is \( \frac{N_{\Xi^{0}_{cc} \pi^{+}}}{N_{\Xi^{0}_{cc} \pi^{-}}} : N_{\Xi^{0}_{cc} K^{-}K^{-} \pi^{+}} = 1:1.15:0.84 \).

Figure 6 (7)(a)-(c) shows the \( M(\Xi_{cc}^{0}(\pi^{+}) \pi^{-}) \) distribution in the \( \Xi^{0}_{cc} \) search region with all the selection cuts applied, overlaid with the MC expectation for the \( \Xi^{0}_{cc} \) at the mass of 3.60 GeV/c^2 with \( \sigma(e^{+}e^{-} \rightarrow \Xi^{0}_{cc}(\pi^{+})X) \) of 500 fb and both \( B(\Xi^{0}_{cc}(\pi^{+}) \rightarrow \Xi^{0}_{cc} \pi^{+}(\pi^{+})) \) and \( B(\Xi^{0}_{cc} \pi^{-} \rightarrow \Xi^{-} \pi^{+}) \) of 5%. The relative yields of signal MC for each decay mode are based on \( N^{0}_{\Xi^{0}_{cc}} \).

A simultaneous UML fit, with the relative \( \Xi_{cc} \) yields constrained as discussed earlier, is applied to evaluate the statistical significance of the \( \Xi^{0}_{cc} \). The signal PDF is described with MC events generated for each decay mode and with the \( \Xi^{0}_{cc} \) mass generated in the search region with a 1 MeV/c^2 step. The mass resolution is 2.7-4.2 MeV/c^2, depending on the mass of the \( \Xi^{0}_{cc} \). The background PDF is modeled as a third-order polynomial. The highest significance is 3.2σ for the mass around 3.553 GeV/c^2 in the \( M(\Xi^{0}_{cc} \pi^{+}) \). We perform a pseudo-experiment test to evaluate the probability of observing a peak with such a statistical significance. A smooth mass distribution based on data is generated and the significance is evaluated in the entire search region. The probability to observe a peak with a significance higher than 3.2σ in one pseudo-experiment is 26%. Therefore, the statistical significance of 3.2σ is insufficient to claim evidence of the \( \Xi^{0}_{cc} \).

The 95% C.L. upper limit for the product of the cross section and branching fractions produced with 0.45 < \( x_{p} < 1.0 \) condition,

\[
\sigma_{B_{2}} \equiv \sigma(e^{+}e^{-} \rightarrow \Xi^{0}_{cc}(\pi^{+})X) \times \frac{B(\Xi^{0}_{cc}(\pi^{+}) \rightarrow \Xi^{0}_{cc} \pi^{+}(\pi^{+})) \times B(\Xi^{0}_{cc} \pi^{-} \rightarrow \Xi^{-} \pi^{+})}{N_{\text{sig}}} = \frac{2L \times \epsilon_{\Xi^{0}_{cc} \pi^{+}} (1 + \frac{N_{\Lambda K^{-}K^{-} \pi^{+}}}{N_{\Xi^{0}_{cc} \pi^{-}}} + \frac{N_{\Xi^{0}_{cc} K^{-}K^{-} \pi^{+}}}{N_{\Xi^{0}_{cc} \pi^{-}}})}{N_{\text{sig}}}
\]

is evaluated with the same method as in section III B. In addition to the sources from the study with the \( \Lambda^{+} \), two others are included here. The systematic uncertainty from the \( \Lambda \) reconstruction efficiency is estimated to be 3% using the yield of the \( B^{+} \rightarrow \Lambda \Lambda K^{+} \) with and without the requirement using decay vertex information. The systematic uncertainties related to \( N_{\Xi^{0}_{c}(2645)^{+}} \) are taken from their statistical errors. The systematic uncertainties are summarized in the fourth column in Table II.
of the mass with a 1 MeV/c^2 step. The 95% C.L. upper limit on $\sigma_{BG}$ is 0.076–0.35 fb for the $\Xi_{cc}^{++}$ and 0.082–0.40 fb for the $\Xi_{cc}^{+}$.

V. CONCLUSION

We have presented a search for doubly-charmed baryons and a study of the charmed strange baryons $\Xi_c(3055)^+$, $\Xi_c(3123)^+$ and $\Xi_c(2645)^+$ using the full data sample (980 fb^{-1}) collected with the Belle detector. The search for doubly charmed baryons is an improved study of our previous work [2]. We use about two times statistics and several additional decay mode, that were not studied in the previous work.

We search for the $\Xi_{cc}$ in the $\Lambda_c^+K^-\pi^+(\pi^+)$ and $\Xi_0^0\pi^+(\pi^+)$ final states. The $\Lambda_c^+$ is reconstructed from the $pK^-\pi^+$ and $pK^0_S$ decay modes. We do not find any significant $\Xi_{cc}$ signal and set a 95% C.L. upper limit on $\sigma(e^+e^- \rightarrow \Xi_{cc}^{+(+)}X) \times B(\Xi_{cc}^{+(+)} \rightarrow \Lambda_c^+K^-\pi^+(\pi^+))$ with the scaled momentum 0.5 < $x_p$ < 1.0: 4.1–25.0 fb for $\Xi_{cc}^+$ and 2.5–26.5 fb for $\Xi_{cc}^{++}$. We also search for the $\Xi_{cc}$ in the $\Xi_0^0\pi^+(\pi^+)$ final state. The $\Xi_0^0$ is reconstructed from the $\Xi^-\pi^+$, $\Lambda K^-\pi^+$, and $pK^-\pi^+$ decay modes. We do not find any significant $\Xi_{cc}$ signal and set a 95% C.L. upper limit on $\sigma(e^+e^- \rightarrow \Xi_{cc}^{+(+)}X) \times B(\Xi_{cc}^{+(+)} \rightarrow \Xi_0^0\pi^+(\pi^+)) \times B(\Xi_0^0 \rightarrow \Xi^-\pi^+)$ with the scaled momentum 0.45 < $x_p$ < 1.0: 0.076–0.35 fb for the $\Xi_{cc}^+$ and 0.082–0.40 fb for the $\Xi_{cc}^{++}$. When we compare these values with the measurements by BaBar, we should note several things.

We should multiply our result by two as written in section III. For the final states with $\Lambda_c^+$, their upper limit is for the product of cross section, $B(\Xi_{cc}^{+(+)} \rightarrow \Lambda_c^+K^-\pi^+(\pi^+))$ and $B(\Lambda_c^+ \rightarrow pK^-\pi^+)$. The values presented in Ref. [34] are the highest upper limits in the search region, which can be compared with our highest values. After taking into account these points, we find our limits represent improvements by about a factor two for the final states with $\Lambda_c^+$ and a factor of four for the final states with $\Xi_0^0$.

If we assume $B(\Xi_{cc}^{+(+)} \rightarrow \Lambda_c^+K^-\pi^+(\pi^+))$, $B(\Xi_{cc}^{+(+)} \rightarrow \Xi_0^0\pi^+(\pi^+))$ and $B(\Xi_{cc}^{+(+)} \rightarrow \Xi_0^0\pi^+(\pi^+))$ to be 5%, which is equal to the $B(\Lambda_c^+ \rightarrow pK^-\pi^+)$, the upper limits on the $\sigma(e^+e^- \rightarrow \Xi_{cc}^{+(+)}X)$ are 82–500 fb ($\Xi_{cc}^{+}X$) and 50–530 fb ($\Xi_{cc}^{++}X$) for the decay mode with the $\Lambda_c^+$ and 30–140 fb ($\Xi_{cc}^{+}X$) and 33–160 fb ($\Xi_{cc}^{++}X$) for the decay mode with the $\Xi_0^0$. These values are comparable to some of the theoretical predictions [28, 29].

We have searched for the $\Xi_c(3055)^+$ and $\Xi_c(3123)^+$ in the $\Lambda_c^+K^-\pi^+$ decays through intermediate $\Sigma_c(2455)^+$ or $\Sigma_c(2520)^+$ states. We observe the $\Xi_c(3055)^+$ with a significance of 6.6$\sigma$, including systematic uncertainty. The mass and width are measured to be 3058.1 ± 1.0 (stat) ± 2.1 (sys) MeV/c^2 and 9.7 ± 3.4 (stat) ± 3.3 (sys) MeV/c^2, respectively. We do not observe any significant signal corresponding to the $\Xi_c(3123)^+$.

The first measurement of the width of the $\Xi_c(2645)^+$ has been also performed, yielding 2.6 ± 0.2 (stat) ± 0.4 (sys) MeV/c^2.

| Decay mode | $N_{\Xi_c(2645)^+}$ | $\epsilon_{\Xi_c(2645)^+}$ |
|------------|----------------------|-----------------------------|
| $\Xi_c^+\pi^+$ | 1298 ± 51 | 0.0748 ± 0.0002 |
| $\Lambda K^-\pi^+$ | 1444 ± 58 | 0.0977 ± 0.0003 |
| $pK^-K^-\pi^+$ | 974 ± 47 | 0.1920 ± 0.0005 |

FIG. 5: Reconstruction efficiencies for the $\Xi_{cc}$ as a function of the $\Xi_{cc}$ mass for (a) $\Xi_{cc}^+$, (b) $\Xi_{cc}^{++}$. Circles, square and triangle points are for $\Xi_{cc}^0 \rightarrow \Xi^-\pi^+$, $\Lambda K^-\pi^+$ and $pK^-K^-\pi^+$, respectively. The lines are the result of the fit with a linear function.

Figure 6 (7) (d) shows $\sigma_{BG}$ for the $\Xi_{cc}^{+(+)}$ as a function of the mass with a 1 MeV/c^2 step. The 95% C.L. upper limit on $\sigma_{BG}$ is 0.076–0.35 fb for the $\Xi_{cc}^+$ and 0.082–0.40 fb for the $\Xi_{cc}^{++}$.
FIG. 6: (a)-(c): $M(\Xi^0_c\pi^+)$ distribution in the $\Xi^+_c$ search region for $\Xi^0_c \rightarrow$ (a) $\Xi^-\pi^+$, (b) $\Lambda K^-\pi^+$, (c) $pK^-K^+\pi^+$. The vertical error bars are from data. The dashed histograms are from signal MC. (d): 95% C.L. upper limit of the $\sigma_{cB}$ for $\Xi^+_c$ as a function of the mass with a 1 MeV/$c^2$ step.
