Abstract

We define and make initial study of Lie groupoids equipped with a compatible homogeneity structure, such objects we will refer to as weighted Lie groupoids. One can think of weighted Lie groupoids as graded bundles in the category of Lie groupoids. This is a very rich geometrical theory with numerous natural examples. Note that VB-groupoids, extensively studied in the recent literature, form just the particular case of weighted Lie groupoids of degree one. We examine the Lie theory related to weighted groupoids and weighted Lie algebroids, objects defined in a previous publication of the authors, which are graded bundles in the category of Lie algebroids, showing that they are naturally related via differentiation and integration. In this work we also make an initial study of weighted Poisson–Lie groupoids and weighted Lie bi-algebroids, as well as weighted Courant algebroids.

MSC (2010): 22A22, 55R10, 58E40, 58H05.

Keywords: graded bundles, homogeneity structures, Lie groupoids, Lie algebroids.
1 Introduction

Lie groupoids and Lie algebroids are ubiquitous throughout differential geometry and are playing an ever increasing role in mathematical physics. Lie groupoids provide a unifying framework to discuss diverse topics in modern geometry including the theory of group actions, foliations, Poisson geometry, orbifolds, principal bundles, connection theory and so on. The infinitesimal counterpart to Lie groupoids are Lie algebroids. The Lie theory here is very rich and not as simple as the corresponding Lie theory for Lie groups and Lie algebras. In particular it is well-known that for every Lie groupoid one can differentiate it to obtain a Lie algebroid, but the reverse procedure of global integration has an obstruction [5, 21]. Not all Lie algebroids can be globally integrated to obtain a Lie groupoid, although one can always integrate Lie algebroids to ‘local’ Lie groupoids.

Another important notion in modern geometry is that of a graded manifold. Such notions have their conception in the ‘super’ context via the BV–BRST formalism of gauge theories in physics. We remark that Lie algebroids appear in physics as symmetries of field theories that do not arise from Lie groups or Lie algebras. Moreover, these symmetries cannot always be directly separated from the space of fields. Such symmetries are naturally accommodated in the BV–BRST formalism. The concept of a graded manifold has been put to good use in describing Lie algebroids, Lie bi-algebroids, Courant algebroids and related notions [32, 33, 36, 38]. In the purely commutative setting, Grabowski & Rotkiewicz [11] define what they referred to as graded bundles. Loosely, a graded bundle is a natural generalisation of the concept of a vector bundle. We will discuss graded bundles in a little more detail shortly.

There has been some recent interest in VB-groupoids and VB-algebroids, see for example [1, 4, 13]. From a categorical point of view VB-groupoids are vector bundles in the category of Lie groupoids and similarly VB-algebroids are vector bundles in the category of Lie algebroids. It is known, via [1, 4], that the Lie functor restricts to the category of VB-groupoids and VB-algebroids; that is we can differentiate VB-groupoids to get VB-algebroids and VB-algebroids integrate to VB-groupoids. Let us mention that VB-groupoids and VB-algebroids have been studied in relation to Poisson geometry and representations. Indeed, representations of Lie groupoids on vector bundles gives rise to VB-groupoids. Moreover the framework of VB-groupoids and VB-algebroids seems to be the natural one to formulate representations up to homotopy, which are needed to make sense of the adjoint representation of Lie groupoids and algebroids.

As graded bundles are generalisations of vector bundles, it seems natural that one should study graded bundles in the category of Lie groupoids and Lie algebroids, including their Lie theory. The first work in this direction was by the authors of this paper, where various descriptions of so-called weighted
Lie algebroids were given in [2]. The motivation for that work was to uncover a practical notion of a “higher Lie algebroid” suitable for higher-order geometric mechanics in the spirit of Tulczyjew. We presented details of the Lagrangian and Hamiltonian formalisms on graded bundles using weighted Lie algebroids in a separate publication [3]. As an application, the higher-order Euler–Lagrange equations on a Lie algebroid were derived completely geometrically, and in full agreement with the independent approach of Martínez using variational calculus [27]. This and other results have convinced us of the potential for further applications of weighted Lie algebroids.

The natural question of integrating weighted Lie algebroids was not posed at all in [2] or [3]. We address this question in this paper. To do this, define weighted Lie groupoids as Lie groupoids that carry a compatible homogeneity structure, i.e. an action of the monoid \( \mathbb{R} \) of multiplicative reals; we will make this precise in due course. We show that these structures, which are a generalisation of \( VB \)-groupoids, are the objects that integrate weighted Lie algebroids. The results found in this paper can therefore be viewed as the ‘higher order’ generalisations of the results found in [1, 4].

Following our intuition, we also examine the notion of weighted Poisson-Lie groupoids as Poisson-Lie groupoids equipped with a compatible homogeneity structure. The infinitesimal versions of weighted Poisson-Lie groupoids are weighted Lie bi-algebroids, a notion we carefully define in this paper. Associated with any Lie bi-algebroid is a Courant algebroid. We show that this notion very naturally passes over to the weighted case and motivates a more general notion of weighted Courant algebroids, which is a natural generalisation of a \( VB \)-Courant algebroid. The use of a compatible homogeneity structure provokes the question of replacing the monoid \( \mathbb{R} \) by its subgroup \( \mathbb{R}^\times \neq 0 \). We claim that this is a natural way of defining contact and Jacobi groupoids.

Summing up, one can say that in this paper we generalise the notion of \( VB \)-‘objects’ (and simultaneously simplify it also) by passing to the category of graded bundles and categorical objects therein. On the other hand, these concepts and their applications are far from being fully exploited. This work is only the first step in this direction.

Our use of supermanifolds: We recognise the power and elegance of the framework of supermanifolds in the context of algebroid-like objects and we will exploit this formalism. In particular we will make use of the so called Q-manifolds, that is supermanifolds equipped with a homological vector field. Although we will not dwell on fundamental issues from the theory of supermanifolds, we will technically follow the “Russian School” and understand supermanifolds in terms of locally superringed spaces. However, for the most part the intuitive and correct understanding of a supermanifold as a ‘manifold’ with both commuting and anticommuting coordinates will suffice. When necessary we will denote the Grassmann parity of an object by ‘tilde’.

Arrangement of paper: In section 2 we briefly recall the necessary parts of theory of graded bundles, weighted Lie algebroids and Lie groupoids as needed in the rest of this paper. In section 3 we introduce the main objects of study, that is weighted Lie groupoids. The related Lie theory is the subject of section 4. Finally in sections 5 we apply some of the ideas developed earlier in this paper to weighted Poisson-Lie groupoids, weighted Lie bi-algebroids and weighted Courant algebroids. We end with some remarks on contact and Jacobi groupoids.

2 Preliminaries

In this section we briefly recall parts of the theory of graded bundles, n-tuple graded bundles and weighted algebroids as needed in later sections of this paper. Everything in this paper will be in the smooth category. The interested reader should consult the original literature [2, 10, 11, 12] for details, such as proofs of the statements made in this section. We will also set some notation regarding Lie groupoids and recall the groupoid/algebroid version of Lie’s second theorem, which was first proved by Mackenzie & Xu [24]. For an overview of the general theory of Lie groupoids and Lie algebroids the reader can consult Mackenzie [25]. We will also very briefly recall the notion of a Q-manifold and a QS-manifold as needed throughout this paper.

2.1 Graded and n-tuple graded bundles

Manifolds and supermanifolds that carry various extra gradings on their structure sheaf are now an established part of modern geometry and mathematical physics. The general theory of graded manifolds in our understanding was initiated by Voronov in [36]. The graded structure on such (super)manifolds is conveniently encoded in the weight vector field whose action via the Lie derivative counts the degree of tensor and tensor-like objects on the (super)manifold.
In this introductory section we will concentrate our attention on just genuine manifold and only sketch the theory for supermanifolds, as the extension of the results here to supermanifolds is completely straightforward. In later sections we will make use of supermanifolds that carry additional gradings coming from a homogeneity structure which will be defined in a moment.

An important class of ‘graded manifolds’ are those that carry non-negative grading. It will be convenient to denote homogeneous local coordinates in the form \((y^a_0, \ldots, y^a_k)\) (or \((y^{a_0}_0, \ldots, y^{a_k}_k)\)), where \(w = 0, 1, \ldots, k\) is the weight of \(y^a_w\). A canonical example of such a structure is the bundle \(T^kM = J^k_\infty(R, M)\) of \(k\)-velocities, i.e. 4th-jets (at 0) of curves \(\gamma : \mathbb{R} \to M\). We will furthermore require that (like in the case of \(T^kM\)) this grading is associated with a smooth action \(h : \mathbb{R}_{\geq 0} \times F \to F\) of the monoid \((\mathbb{R}_{\geq 0}, \cdot)\) of multiplicative reals on a manifold \(F\). Let us recall in this context that a function \(f \in C^\infty(F)\) we call homogeneous of degree \(k \in \mathbb{R}\) if

\[
h^*_k(f) := f(h(t, \cdot)) = t^k f
\]

for all \(t > 0\). We call \(k\) also the weight of \(f\).

Such actions are known as homogeneity structures in the terminology of Grabowski & Rotkiewicz \[11\] who proved that only non-negative integer weights are allowed, so the algebra \(\mathcal{A}(F) \subset C^\infty(F)\) spanned by homogeneous function has a canonical \(N\)-grading, \(\mathcal{A}(F) = \bigoplus_{i \in \mathbb{N}} \mathcal{A}^i(F)\). This algebra is referred to as the algebra of polynomial functions on \(F\). This action reduced to \(\mathbb{R}_{>0}\) is the one-parameter group of diffeomorphism integrating the weight vector field, thus the weight vector field is in this case \(h\)-complete \[12\]. Note also that the homogeneity structure always has a canonical extension to the action \(h : \mathbb{R} \times F \to F\) of the monoid \((\mathbb{R}, \cdot)\) such that any homogeneous function \(f\) of degree \(k \in \mathbb{N}\) satisfies \((2.1)\) this time for all \(t \in \mathbb{R}\); it will be convenient to speak about a homogeneity structure as this extended action.

Importantly, we have that for \(t \neq 0\) the action \(h_t\) is a diffeomorphism of \(F\) and when \(t = 0\) it is a smooth surjection \(\tau = h_0\) onto a submanifold \(\bar{F}_0 = M\), with the fibres being diffeomorphic to \(R^N\) (c.f. \[11\]). Thus, the objects obtained are particular kinds of polynomial bundles \(\tau : F \to M\), i.e. fibrations which locally look like \(U \times \mathbb{R}^N\) and the change of coordinates (for a certain choice of an atlas) are polynomial in \(\mathbb{R}^N\). For this reason graded manifolds with non-negative weights and \(h\)-complete weight vector fields are also known as graded bundles \[11\]. Furthermore, the \(h\)-completeness condition implies that graded bundles are determined by the algebra of homogeneous functions on them. Canonical examples of graded bundles are higher tangent bundles \(T^kM\). The canonical coordinates \((x^a, \bar{x}^b, \bar{x}^c, \ldots)\) on \(T^kM\), associated with local coordinates \((x^a)\) on \(M\), have degrees, respectively, 0, 1, 2, ..., so the homogeneity structure reads

\[
h_t(x^a_0, \bar{x}^b_0, \bar{x}^c_0, ...) = (x^a_0, t\bar{x}^b_0, t^2\bar{x}^c_0, \ldots).\]

A fundamental result is that any smooth action of the multiplicative monoid \((\mathbb{R}, \cdot)\) on a manifold leads to a \(N\)-gradation of that manifold. A little more carefully, the category of graded bundles is equivalent to the category of \((\mathbb{R}, \cdot)\)-manifolds and equivariant maps. A canonical construction of this correspondence goes as follows. Take \(p \in F\) and consider \(t \mapsto h_t(p)\) as a smooth curve \(\gamma^p_h\) in \(F\). This curve meets \(M\) for \(t = 0\) and is constant for \(t \in M\).

**Theorem 2.1.1** \([\text{III}]\). For any homogeneity structure \(h : \mathbb{R} \times F \to F\) there is \(k \in \mathbb{N}\) such that the map

\[
\Phi^k_h : F \to T^kM, \quad \Phi^k_h(p) = h^k_0(\gamma^p_h),
\]

is an equivariant (with respect to the monoid actions of \((\mathbb{R}, \cdot)\) on \(F\) and \(T^kM\)) embedding of \(F\) onto a graded submanifold of the graded bundle \(T^kM\). In particular, there is an atlas on \(F\) consisting of homogeneous function.

Any \(k\) described by the above theorem we call a degree of the homogeneity structure \(h\).

**Remark 2.1.2.** The above theorem has its obvious counterpart for graded supermanifolds. Following Voronov we do not require that weights induce parity. The compatibility condition just means that \(N\)-weights commute with \(Z_2\)-grading. In other words, a homogeneity structure on a supermanifold \(M\) is a smooth action \(h : \mathbb{R} \times M \to M\) of the monoid \((\mathbb{R}, \cdot)\) such that \(h_t : M \to M\) are morphisms, i.e. respect the parity. Equivalently, we have an \((\mathbb{R}, \cdot)\)-action on the super-algebra \(\mathcal{O}_M = C^\infty(M)\) by homomorphisms. Commutation with parity immediately induces a homogeneity structure (denoted also \(h\) with some abuse of notation) on the body \(F = |M|\) of \(M\), thus on the quotient algebra \(\mathcal{O}_F = C^\infty(F)\) of \(\mathcal{O}_M\) modulo the ideal generated by nilpotents.

The embedding of \(M\) into a certain higher tangent superbundle can be derived as follows. The above ‘even’ theorem implies that \(F\) is a graded bundle over \(M = h_0(F)\), so there is a splitting \(O_F = O^k_F \oplus O^0_F\), where \(O^k_F\) is the kernel, and \(O^0_F = C^\infty(M) =: O_M\) is the image of the projection \(h^*_0 : O_F \to O_F\).
Consider the submanifold \( M_{1|\mathcal{M}} \) of \( \mathcal{M} \) defined by \( \mathcal{O}_p^0 = 0 \), i.e. the restriction to \( \mathcal{M} \) of the ringed space corresponding to \( \mathcal{M} \). It carries an induced homogeneity structure and the algebra \( \mathcal{O}_{M_{1|\mathcal{M}}} \) of superfunctions on \( M_{1|\mathcal{M}} \) is a \( \mathcal{O}_{\mathcal{M}} \)-module. As \( h^* \) acts identically on \( \mathcal{O}_M \) we can view the \( \mathbb{R} \)-action \( h^* \) on \( \mathcal{O}_{M_{1|\mathcal{M}}} \), at least locally, as a family of actions \( h^*(p) : \mathcal{M} \to \mathcal{M} \) on the Grassmann algebra \( \Lambda \) generated by local odd coordinates \( \vartheta^1, \ldots, \vartheta^n \) on \( \mathcal{O}_{M_{1|\mathcal{M}}} \), indexed by \( p \in \mathcal{M} \). Let \( \Lambda = \Lambda^0(p) \oplus \Lambda^1(p) \) be the splitting associated with the projection \( h_0^*(p) \). It is easy to see that \( \Lambda^0(p) \) is an ideal generated by its elements \( \vartheta^1(p), \ldots, \vartheta^n(p) \) spanning the linear part \( \Lambda^0(p)/\Lambda^2(p) \), and that the subalgebra \( \Lambda^1(p) \) is generated by its elements \( \xi^1(p), \ldots, \xi^n(p) \), \( r + q = s \), spanning its linear part. Note that \( r \) and \( q \) do not depend on \( p \) (for a connected \( M \)), as a continuous family of projections must have a constant rank. Since \( h^* \) respects the parity, we can choose \( \xi^i(p) \) and \( \vartheta^j(p) \) to be odd and, locally, smoothly depending on \( p \), and view them as new odd coordinates \( \xi^1, \ldots, \xi^n \) in \( \mathcal{O}_{M_{1|\mathcal{M}}} \). It is easy to see now that \( h_0(M) \) is a smooth super-submanifold \( M_0 \) of \( h_0(M_{1|\mathcal{M}}) \) defined locally by \( \vartheta^1 = \cdots = \vartheta^n = 0 \). Local coordinates on \( M_0 \) consists of (even) local coordinates on \( M \) and odd coordinates \( (\xi^i) \). Now, one can prove the existence of an embedding \( \Psi^M_k : M \to T^k M_0 \) analogously to what have been done in [11] for the pure even case.

Morphisms between graded bundles are necessarily polynomial in the non-zero weight coordinates and respect the weight. Such morphisms can be characterised by the fact that they relate the respective weight vector fields [11].

**Remark 2.1.3.** It is possible to consider manifolds with gradations that do not lead to complete weight vector fields. From the point of view of this paper such manifolds are less rigid in their structure and will exhibit pathological behavior. As we will use graded supermanifolds in this work, we remark that the definition given by Voronov [35] of a non-negatively graded supermanifold states that the Grassmann even coordinates are ‘cylindrical’. This together with the fact that functions of Grassmann odd coordinates are necessarily polynomial, means that the weight vector fields on non-negatively graded supermanifolds and the closely related N-manifolds are h-complete.

A graded bundle of degree \( k \) admits a sequence of polynomial fibrations, where a point of \( F_t \) is a class of the points of \( F \) described in an affine coordinate system by the coordinates of weight \( \leq l \), with the obvious tower of surjections

\[
F = F_k \xrightarrow{\tau^1} F_{k-1} \xrightarrow{\tau^2} \cdots \xrightarrow{\tau^2} F_2 \xrightarrow{\tau^1} F_1 \xrightarrow{\tau^1} F_0 = M, \tag{2.3}
\]

where the coordinates on \( M \) have zero weight. Note that \( F_1 \to M \) is a linear fibration and the other fibrations \( F_t \to F_{t-1} \) are affine fibrations in the sense that the changes of local coordinates for the fibres are linear plus and additional additive terms of appropriate weight. The model fibres here are \( \mathbb{R}^N \) (c.f. [11]). We will also use on occasion \( \tau := \tau^k_k : F_k \to M \).

Canonical examples of graded bundles are, for instance, vector bundles, \( n \)-tuple vector bundles, higher tangent bundles \( T^k M \), and multivector bundles \( \wedge^n TE \) of vector bundles \( \tau : E \to M \) with respect to the projection \( \wedge^n T^kM \to \wedge^n TE \to \wedge^n TM \) (see [3]). If the weight is constrained to be either zero or one, then the weight vector field is precisely a vector bundle structure on \( F \) and will be generally referred to as an Euler vector field.

The notion of a double vector bundle [31] (or a higher \( n \)-tuple vector bundle) is conceptually clear in the graded language in terms of mutually commuting homogeneity structures, or equivalently weight vector fields; see [10] [11]. This leads to the higher analogues known as \( n \)-tuple graded bundles, which are manifolds for which the structure sheaf carries an \( \mathbb{N}^n \)-grading such that all the weight vector fields are h-complete and pairwise commuting. In particular a double graded bundle consists of a manifold and a pair of mutually commuting weight vector fields. If all the weights are either zero or one then we speak of an \( n \)-tuple vector bundle.

### 2.2 Q-manifolds and related structures

Let us briefly define some structures on supermanifolds that we will employ throughout this paper. The main purpose is to set some nomenclature and notation following Voronov [35]. The graded versions will be fundamental throughout this paper.

**Definition 2.2.1.** An odd vector field \( Q \in \text{Vect}(\mathcal{M}) \) on a supermanifold \( \mathcal{M} \) is said to be a homological vector field if and only if \( 2Q^2 = [Q, Q] = 0 \). Note that, as we have an odd vector field, this condition is generally non-trivial. A pair \( (\mathcal{M}, Q) \), where \( \mathcal{M} \) is a supermanifold and \( Q \in \text{Vect}(\mathcal{M}) \) is called a \( Q \)-manifold. A morphism of \( Q \)-manifolds is a morphism of supermanifolds that relates the respective homological vector fields.
As is well-known, Q-manifolds, equipped with an additional grading, give a very economical description of Lie algebroids as first discovered by Vaintrob [35]. Recall the standard notion of a Lie algebroid as a vector bundle \( E \to M \) equipped with a Lie bracket on the sections \( \{\cdot, \cdot\} : \text{Sec}(E) \times \text{Sec}(E) \to \text{Sec}(E) \) together with an anchor \( \rho : \text{Sec}(E) \to \text{Vect}(M) \) that satisfy the Leibniz rule
\[
[u, f v] = \rho(u)[f] v + f[u, v],
\]
for all \( u \& v \in \text{Sec}(E) \) and \( f \in C^\infty(M) \). The Leibniz rule implies that the anchor is actually a Lie algebra morphism: \( \rho([u, v]) = [\rho(u), \rho(v)] \). If we pick some local basis for the sections \( (e_a) \), then the structure functions of a Lie algebroid are defined by
\[
[e_a, e_b] = C_{ab}^c(x)e_c,
\]
\[
\rho(e_a) = \rho_a^i(x)\frac{\partial}{\partial x^i},
\]
were we have local coordinates \((x^A)\) on \( M \). These structure functions satisfy some compatibility conditions which can be neatly encoded in a homological vector field of weight one on \( \Pi E \). Let us employ local coordinates
\[
\{ x^A, \xi^a \}
\]
on \( \Pi E \). Here the weight of coordinates corresponds to the natural weight induced by the homogeneity structure associated with the vector bundle structure [10] and this also corresponds to the Grassmann parity. We just briefly remark that one can also define Lie algebroids in the category of supermanifolds where it natural to consider the weight and Grassmann parity as being independent. The homological vector field encoding the Lie algebroid is
\[
Q = \xi^a \rho^A_a(x)\frac{\partial}{\partial x^A} + \frac{1}{2}\xi^a \xi^b C_{ba}^c(x)\frac{\partial}{\partial \xi^c}.
\]
The axioms of a Lie algebroid are then equivalent to \( 2Q^2 = [Q, Q] = 0 \). We will, by minor abuse of nomenclature, also refer to the graded Q-manifold \( (\Pi E, Q) \) as a Lie algebroid.

A morphism of Lie algebroid is then understood as a morphism of graded Q-manifolds. That is we have a morphism of super graded bundles that relates the respective homological vector fields. Note that the definition of a Lie algebroid morphism in terms of Q-manifold morphisms is equivalent to the less obvious notion of a morphism of Lie algebroids as described in [25].

**Example 2.2.2.** Any Lie algebra \((\mathfrak{g}, [,])\) can be encoded in a homological vector field on the linear supermanifold \( \Pi \mathfrak{g} \). Let us employ local coordinates \( (\xi^a) \) on \( \Pi \mathfrak{g} \); then we have
\[
Q = \frac{1}{2}\xi^a \xi^b C_{ba}^c\frac{\partial}{\partial \xi^c},
\]
where \( C_{ba}^c \) is the structure constant of the Lie algebra in question. In this case the base manifold is just a point and the anchor map is trivial.

**Example 2.2.3.** In the other extreme, the tangent bundle of a manifold \( TM \) is naturally a Lie algebroid for which the anchor is the identity map. The homological vector on \( \Pi TM \) that encodes the Lie algebroid structure is nothing other than the de Rham differential.

**Definition 2.2.4.** An odd Hamiltonain \( S \in C^\infty(T^*M) \) that is quadratic in momenta (i.e. fibre coordinates) is said to be a Schouten structure if and only if \( \{S, S\} = 0 \), where the bracket is the canonical Poisson bracket on the cotangent bundle. A pair \((M, S)\), where \( M \) is a supermanifold and \( S \in C^\infty(T^*M) \) is a Schouten structure, is called a \( S \)-manifold. The associated Schouten bracket on \( C^\infty(M) \) is given as a derived bracket
\[
[f, g]_S := \{\{f, S\}, g\}.
\]

We must remark here that non-trivial Schouten structures only exist on supermanifolds. A Schouten bracket is also known as an odd Poisson bracket and satisfies the appropriate graded versions of the Jacobi identity and Leibniz rule.
Example 2.2.5. A Lie algebroid structure on a vector bundle $E \to M$ can be encoded in a weight one Schouten structure on the supermanifold $T^*\Pi E^*$. Let us employ natural local coordinates on $T^*\Pi E^*$ (with indicated bi-degrees)

\[
\begin{pmatrix}
  x^A \\
  \chi_a \\
  p_B \\
  \psi_b 
\end{pmatrix}
\]

Then, the Schouten structure encoding a Lie algebroid is given by

\[
S = \theta^\rho \rho^A \rho^B + \frac{1}{2} \theta^\rho \theta^C \rho^{bc} \chi_c
\]

and the axioms of a Lie algebroid are equivalent to $\{S, S\} = 0$, where the bracket here is the canonical Poisson bracket on the cotangent bundle.

Definition 2.2.6. A supermanifold $M$ is said to be a QS-manifold if it is simultaneously a Q-manifold and an S-manifold such that $L_Q S := \{Q, S\} = 0$, where $Q \in C^\infty(T^*M)$ is the symbol of the homological vector field $Q$.

As the symbol map sends the Lie bracket of vector fields to the Poisson bracket, a QS-manifold can be considered as a supermanifold equipped with odd Hamiltonians, one linear and one quadratic in momenta, that satisfy $\{Q, Q\} = 0$, $\{S, S\}$ and $\{Q, S\} = 0$.

Graded QS-manifolds give us a convenient way to understand Lie bi-algebroids, which is due to Voronov [36], but also see Kosmann-Schwarzbach [19] who modified the original definition of Mackenzie & Xu [22]. The original definition involved the differential associated with the dual Lie algebroid and Lie bracket on sections of the Lie algebroid, and not the associated Schouten bracket on ‘multivector fields’. Following Kosmann-Schwarzbach, a Lie bi-algebroid is a pair of Lie algebroids $(E, E^*)$ such that

\[
Q_E[X, Y]_{E^*} = [Q_E X, Y]_{E^*} + (-1)^{\tilde{X}} [X, Q_E Y]_{E^*},
\]

for all ‘multivector fields’ $X$ and $Y \in C^\infty(\Pi E)$. That is the homological vector field encoding the Lie algebroid structure on $E$ must be a derivation with respect to the Schouten bracket that encodes the Lie algebroid structure on the dual vector bundle $E^*$. It is not hard to see that this definition is equivalent to the compatibility condition

\[
\mathcal{L}_{Q_E} S_{E^*} = \{Q_E, S_{E^*}\} = 0,
\]

and so we have a QS-manifold. Here we use the canonical isomorphism $T^*\Pi E \simeq T^*\Pi E^*$. In natural local coordinates the symbol of the homological vector field and the Schouten structure are given by

\[
Q_E = \theta^\rho \rho^A \rho^B + \frac{1}{2} \theta^\rho \theta^C \rho^{bc} \chi_c,
\]

\[
S_{E^*} = \chi_a \rho^A \rho^B + \frac{1}{2} \chi_a \chi_b \rho^{bc} \psi_c
\]

which are clearly of bi-weight $(2, 1)$ and $(1, 2)$ respectively. We can then define a Lie bi-algebroid as the graded QS-manifold $(T^*\Pi E, Q_E, S_{E^*})$.

The above definition of a Lie bi-algebroid is not manifestly symmetric in $E$ and $E^*$, however, due to the isomorphism

\[
(T^*\Pi E, Q_E, S_{E^*}) \simeq (T^*\Pi E^*, S_{E^*}, Q_E),
\]

it is clear that if $(E, E^*)$ is a Lie bi-algebroid, then so is $(E^*, E)$.

2.3 Weighted Lie algebroids

One can think of a weighted Lie algebroid as a Lie algebroid in the category of graded bundles or, equivalently, as a graded bundle in the category of Lie algebroids [2]. Thus one should think of weighted Lie algebroids as Lie algebroids that carry an addition compatible grading. For the purposes of this paper, we will define weighted Lie algebroids here using the notion of homogeneity structures as this will turn out to be a useful point of view when dealing with the associated Lie theory. Let us recall the definition of a graded-linear bundle, which is fundamental in the notion of a weighted Lie algebroid.

Definition 2.3.1. A manifold $D(k-1,1)$ equipped with a pair of homogeneity structures $(\hat{h}, \hat{l})$ of degree $k-1$ and $1$ respectively is called a graded-linear bundle of degree $k$, which we will abbreviate as $GL$-bundle, if and only if the respective actions commute.
The above definition is equivalent to the definition given in [2] in terms of mutually commuting h-complete weight vector fields of degree \( k - 1 \) and \( 1 \). In all, by passing to total weight, a \( GL \)-bundle is a graded bundle of degree \( k \). We will denote the base defined by the vector bundle structure as \( B_k = M \). We will generally employ the shorthand notation \( D_k \) for a \( GL \)-bundle \( D(k-1,1) \) of degree \( k \) in this paper.

**Example 2.3.2.** (2) Let \( F_{k-1} \) be a graded bundle of degree \( k - 1 \), then \( TF_{k-1} \) is canonically a \( GL \)-bundle of degree \( k \). The degree \( k - 1 \) homogeneity structure is simply the tangent lift of the homogeneity structure on the initial graded bundle, while the degree one homogeneity structure is that associated with the natural vector bundle structure of the tangent bundle. That is, if we equip \( F_{k-1} \) with local coordinates \((x^a_0, \delta x^b_{u+1})\), here \( 0 \leq u < k \), then \( TF_{k-1} \) can be naturally equipped with coordinates

\[
\begin{pmatrix}
(x^a_0, \delta x^b_{u+1}) \\
(u,0) \\
(u,1)
\end{pmatrix}
\]

**Example 2.3.3.** (2) Similarly to the above example, if \( F_{k-1} \) be a graded bundle of degree \( k - 1 \), then \( T^*F_{k-1} \) is canonically a \( GL \)-bundle of degree \( k \). Note there we have to employ a phase lift of the homogeneity structure on \( F_{k-1} \) to ensure that we do not leave the category of graded bundles [13]; that is, we do not want negative weight coordinates. This amounts to an appropriate shift in the weight and allows us to employ homogeneous local coordinates of the form

\[
\begin{pmatrix}
(x^a_0, \delta x^b_{u+1}) \\
(0,0) \\
(k-1-u,1)
\end{pmatrix}
\]

Note that as we have a linear structure on \( GL \)-bundles, that is we have a homogeneity structure of weight one, or equivalently an Euler vector field, applying the parity reverson functor makes sense. Thus, we can consider the \( GL \)-antibundle \((\Pi D_k, \Pi \tilde{H}, \Pi \tilde{H})\), where we define viz

\[\Pi \tilde{H}_t : \Pi D_k \to \Pi D_k,\]

and similarly for \( \Pi \tilde{H} \). We can now define a weighted Lie algebroid as follows;

**Definition 2.3.4.** A weighted Lie algebroid of degree \( k \) is the quadruple

\[(\Pi D_k, \Pi \tilde{H}, \Pi \tilde{H}, Q),\]

where \((\Pi D_k, Q)\) is a Q-manifold and \((\Pi D_k, \Pi \tilde{H}, \Pi \tilde{H})\) is a \( GL \)-antibundle such that

\[
Q \circ (\Pi \tilde{H}_t)^* = (\Pi \tilde{H}_t)^* \circ Q, \tag{2.8}
\]

\[
sQ \circ (\Pi \tilde{H}_s)^* = (\Pi \tilde{H}_s)^* \circ Q, \tag{2.9}
\]

for all \( t \) and all \( s \in \mathbb{R} \).

The above definition is really just the statement that a weighted Lie algebroid can be defined as a \( GL \)-antibundle equipped with a homological vector of bi-weight \((0,1)\).

**Example 2.3.5.** It is not hard to see that a weighted Lie algebroid of degree \( 1 \) is just a standard Lie algebroid; the additional homogeneity structure is trivial and so we have a graded super bundle of degree one and a weight one homogeneity vector field.

**Example 2.3.6.** Similarly to the previous example, weighted Lie algebroids of degree \( 2 \) (i.e. of bi-degree \((1,1)\)) are \( VE \)-algebroids; we now have a double super vector bundle structure and a weight \((0,1)\) homological vector field [13].

Further natural examples of weighted Lie algebroids include the tangent bundle of a graded bundle and the higher order tangent bundles of a Lie algebroid, see [2].

The above definition allows for a further more economical definition via the following proposition, which follows immediately from (2.8).

**Proposition 2.3.7.** A weighted Lie algebroid of degree \( k \) can equivalently be defined as a Lie algebroid \((\Pi E, Q)\) equipped with a homogeneity structure of degree \( k - 1 \) such that

\[\Pi \tilde{H}_t : \Pi E \to \Pi E,\]

is a Lie algebroid morphism for all \( t \in \mathbb{R} \).
To get a more traditional description of a weighted Lie algebroid, let us employ homogeneous local coordinates

\[
(s^u_\alpha, \theta^{u+1}_{\alpha+1}, (u, 0), (u, 1))
\]
on \Pi D_k, where \(0 \leq u \leq k - 1\) and this label refers to the total weight. Note that the second component of the bi-weight encodes the Grassmann parity of the coordinates; that is the \(\theta's\) are anticommuting coordinates. In these homogeneous local coordinates the homological vector field encoding the structure of a weighted Lie algebroid is

\[
Q = \theta^{l}_{u-u'+1}Q^I_j[u'](x) \frac{\partial}{\partial x^\alpha} + \frac{1}{2} \theta^{l}_{u-w+1} \theta^{l}_{u-w+1}Q^K_l[u'](x) \frac{\partial}{\partial \theta^{u+1}_{K+1}}, \tag{2.10}
\]
where \(Q^I_j[u']\) and \(Q^K_l[u']\) are the homogeneous parts of the structure functions of degree \(u'\). In the notation employed here, any \(\theta\) with seemingly zero or negative total weight are set to zero.

In [2] homogeneous linear sections of \(D_k \to B_{k-1}\) of weight \(r\) were defined functions on the \(GL\)-bundle \(D_k^r\) of bi-weight \((r - 1, 1)\). Let us equip \(D_k^r\) with homogeneous local coordinates

\[
(s^u_\alpha, \pi^{u+1}_I, (u, 0), (u, 1))
\]
in these local coordinates a linear section on \(D_k\) is given by

\[
s_r = s^{l}_{r-u-1}(x)\pi^{u+1}_I. \tag{2.11}
\]
Such linear sections can also be understood as vertical vector fields constant along the fibres of \(\Pi D_k\). In the graded language we consider vector fields that are of weight \(-1\) with respect to the second component of the bi-weight on \(\Pi D_k\). Note that we have a shift in the bi-weight and also the Grassmann parity. The reason we use \(\Pi D_k\) rather than \(D_k\) will become clear in a moment when we consider how to construct the Lie algebroid bracket and the anchor. By employing the homogeneous local coordinates on \(\Pi D_k\) introduced perviously we have the identification

\[
s_r \leftrightarrow i_{s_r} := s^{l}_{r-u-1}(x) \frac{\partial}{\partial \theta^{k-u}_{K}}, \tag{2.12}
\]
which is really no more than the ‘interior product’ generalised to sections of a vector bundle. Note that we do not require any extra structure here for this identification, just the vector bundle structure is required. Note the shift in the bi-weight \((r - 1, 1) \to (r - k, -1)\), or in other words we have a shift of \((-k - 1, -2)\). This shift will be very important.

We can now employ the derived bracket formalism [20] to construct the Lie algebroid bracket;

\[
i_{[s_1, s_2]} = [[Q, i_{s_1}], i_{s_2}], \tag{2.13}
\]
up to a possible overall minus sign by convention. By inspection we see that \(i_{[s_1, s_2]}\) is of bi-weight \((r_1 + r_2 - 2k, -1)\), where \(s_1\) is a linear section of degree \(r_1\) and similarly for \(s_2\). This means that the Lie algebroid bracket \([s_1, s_2]\) is of bi-weight \((r_1 + r_2 - 1 - k, 1)\); that is the Lie algebroid bracket carries weight \(-k\).

**Definition 2.3.8.** A morphism of weighted Lie algebroids is a morphism of the underlying Lie algebroids (understood as a morphism of \(Q\)-manifolds) that intertwines the respective additional homogeneity structures.

In particular, weighted Lie algebroids form a subcategory of Lie algebroids, but not a full subcategory. We will denote the category of Lie algebroids as \(\text{Alg}\) and the subcategory of weighted Lie algebroids as \(w\text{Alg}\).

**Proposition 2.3.9.** If \((\Pi D_k, Q)\) is weighted Lie algebroid of degree \(k\), then each \(\Pi D_j\) for \(0 \leq j < k\) comes with the structure of a weighted Lie algebroid of degree \(j\). In particular, \(\Pi E = \Pi D_j\) is a ‘genuine’ Lie algebroid. Moreover, the projection form any ‘higher level’ to a ‘lower level’ is a morphism of weighted Lie algebroids.
\textbf{Proof.} Because of the condition that the weight of }Q\text{ is } (0, 1)\text{ and that there are no negatively graded coordinates, we know that }Q\text{ is projectable to any of the \textquote{levels} of the affine fibrations

$$\Pi D_{(k-1,1)} \to \Pi D_{(k-2,1)} \to \cdots \to \Pi D_{(1,1)} \to \Pi D_{(0,1)}.$$ \hfill (2.14)

This can be directly checked using the local expression for the homological vector field. Moreover, the project of }Q\text{ to any level is a homological vector field of weight } (0, 1)\text{ and hence we have the structure of a weighted Lie algebroid. The fact that the projections give rise to weighted Lie algebroid morphisms follows directly. \hfill \square

\subsection{2.4 Lie groupoids}

Here we shall set some notation and recall some well-known results. Let }G \equiv M\text{ be an arbitrary Lie groupoid with source map }s : G \to M\text{ and target map }t : G \to M\text{. There is also the inclusion map }\iota : M \to G\text{ and a \textit{partial multiplication} } (g, h) \mapsto g \cdot h\text{ which is defined on }G^{(2)} = \{(g, h) \in G \times G : s(g) = t(h)\}.\text{ Moreover, the manifold }G\text{ is foliated by }s\text{-fibres }G_x = \{x \in G : s(x) = x\},\text{ where }x \in M\text{. As by definition the source and target maps are submersions, the }s\text{-fibres are themselves smooth manifolds. Geometric objects associated with this foliation will be given the superscript }s.\text{ In particular, the distribution tangent to the leaves of the foliation will be denoted by }T^sG.\text{ To ensure no misunderstanding with the notion of a Lie groupoid morphism we recall the definition we will be using;}

\textbf{Definition 2.4.1.} Let }G_{i} \equiv M_{i} \text{ (}i = 1, 2\text{) be a pair of Lie groupoids. Then a \textit{Lie groupoid morphisms} is a pair of maps } (\Phi, \phi)\text{ such that the following diagram is commutative}

$$
\begin{array}{ccc}
G_1 & \xrightarrow{\Phi} & G_2 \\
\downarrow{\Phi_1} & & \downarrow{\Phi_2} \\
M_1 & \xrightarrow{\phi} & M_2
\end{array}
$$

subject to the further condition that }\Phi\text{ respect the (partial) multiplication; if }g, h \in G_i\text{ are composable, then }\Phi(g \cdot h) = \Phi(g) \circ \Phi(h).\text{ It then follows that for }x \in M_1\text{ we have }\Phi(\iota_x) = \iota_{\Phi(x)}\text{ and }\Phi(g^{-1}) = \Phi(g)^{-1}.

We will denote the category of Lie groupoids as }\textbf{Grpd}.\text{ It is well known that via a differentiation procedure one can construct the \textit{Lie functor}

$$\textbf{Grpd} \xrightarrow{\text{Lie}} \textbf{Algd},$$

that sends a Lie groupoid to its Lie algebroid, and send morphisms of Lie groupoids to morphisms of the corresponding Lie algebroids. However, as is also well known, we do not have an equivalence of categories as not all Lie algebroids arise as the infinitesimal versions of Lie groupoids. There is no direct generalisation of Lie III, apart from the local case. The obstruction to the integrability of Lie algebroids, the so called \textit{monodromy groups}, were first uncovered by Cranic \& Ferandes [5]. For the transitive case the topological obstruction was uncovered by Mackenzie [21]. The interested reader can consult the original literature or the very accessible lecture notes also by Cranic \& Ferandes [6]. To set some notation and nomenclature, given a Lie groupoid }G,\text{ we say that }\text{Lie}(G) = A(G)\text{ \textit{integrates} }A(G).\text{ Moreover, if }\Phi : G \to H\text{ is a morphism of Lie groupoids, then we will write }\Phi' = \text{Lie}(\Phi) : A(G) \to A(H)\text{ for the corresponding Lie algebroid morphism, which actually comes from the differential }T\Phi : T^sG \to T^sH\text{ restricted to }s\text{-fibres at submanifold of }M.

Let us just recall Lie II theorem as we will need it later on;

\textbf{Theorem 2.4.2. (Lie II)}

\textit{Let }G \equiv M\text{ and }H \equiv N\text{ be Lie groupoids. Suppose that }G\text{ is source simply-connected and that }\phi : A(G) \to A(H)\text{ is a Lie algebroid morphism between the associated Lie algebroids. Then, }\phi\text{ integrates to a unique Lie groupoid morphisms }\Phi : G \to H\text{ such that }\Phi' = \phi.\text{ This generalisation of Lie II to the groupoid case was first proved by Mackenzie \& Xu [24]. A simplified proof was obtained shortly after by Moerdijk \& J. Mrčun [30]. Note that the Lie groupoid }G\text{ must be source simply-connected.}
3 Weighted Lie groupoids

To avoid any possible confusion with the overused adjective ‘graded’, following the nomenclature in [2] we will refer to weighted rather than graded Lie groupoids. We remark that the term ‘graded groupoid’ appears in the work of Mehta [28] as groupoids in the category of graded supermanifolds, not necessarily non-negatively graded. In this work we will content ourselves with working in the strictly commutative setting. The basic idea is to take the definition of a Lie groupoid and replace ‘smooth manifold’ everywhere with ‘graded bundle’. To do this economically we will make use of the description of graded bundles in terms of smooth manifolds equipped with a homogeneity structure of degree \( k \), so that morphisms of graded bundles are just smooth maps intertwining the respective homogeneity structures. In essence, we require that the Lie groupoid structure functions respect the graded structure which is encoded in the homogeneity structure.

### 3.1 The definition of weighted Lie groupoids via homogeneity structures

Let us formalise the comments in the beginning of this section with the following definition;

**Definition 3.1.1.** A weighted Lie groupoid of degree \( k \) is a Lie groupoid \( \Gamma_k \Rightarrow B_k \), together with a homogeneity structure \( h_t : \mathbb{R} \times \Gamma_k \rightarrow \Gamma_k \) of degree \( k \), such that \( h_t \) is a Lie groupoid morphism for all \( t \in \mathbb{R} \). Such homogeneity structures we be referred to as multiplicative homogeneity structures.

**Remark 3.1.2.** Equivalently one could think of a weighted Lie groupoid in terms of multiplicative weight vector fields. This follows from the definition of a weighted Lie groupoid and the fact that weight vector fields associated with homogeneity structures are complete. However, it will be convenient to use the homogeneity structures rather than weight vector fields from the perspective of Lie theory.

Let us unravel some of the structure here. First as both the source and target maps are submersions and by assumption \( \Gamma_k \) is a graded bundle of degree \( k \), \( B_k \) is also a graded bundle of degree \( k \), as we will consider lower degree graded bundles to be included as higher degree graded bundles if necessary. Secondly, it will be convenient to consider the homogeneity structure \( h_t \) as a pair of structures: \( h_t = (h_t^s, h_t^g) \). Then consider the following commutative diagram,

\[
\begin{array}{ccc}
\Gamma_k & \xrightarrow{h_t} & \Gamma_k \\
\downarrow & & \downarrow \\
B_k & \xrightarrow{g_t} & B_k \\
\end{array}
\]

which means that

\[ s \circ h_t = g_t \circ s \quad \text{and} \quad t \circ h_t = g_t \circ t. \]

That is, the source and target maps intertwine the respective homogeneity structure.

Furthermore, we have \( h_t(g \circ h) = h_t(g) \circ h_t(h) \), meaning that the homogeneity structure respects the (partial) multiplication, or indeed vice versa. From the definition of a Lie groupoid morphism, compatibility with the identities and inverses follows. In short, the graded structure is fully compatible with the Lie groupoid structure. Or, in other words, we have a Lie groupoid object in the category of graded bundles or equivalently vice-versa.

**Definition 3.1.3.** A morphism of weighted Lie groupoids is a Lie groupoid morphisms that intertwines the respective homogeneity structures.

In other words, a morphisms of weighted Lie groupoids must in addition to being a morphisms of Lie groupoids, it must be a morphism of graded bundles. We see that we get a subcategory, but not a full subcategory of the category of Lie groupoids. We will denote the category of weighted Lie groupoids as \( \mathcal{wGrpd} \).

### 3.2 Relation with \( \mathcal{VB} \)-groupoids

Bursztyn, Cabrera & de Hoy (c.f. Theorem 3.2.3 [4]) establish a one-to-one correspondence between \( \mathcal{VB} \)-groupoids, which have several equivalent definitions (see for example [14]), and Lie groupoids that have a regular action of \((\mathbb{R}, \cdot)\) as Lie groupoid morphisms. In essence, they show the equivalence between \( \mathcal{VB} \)-groupoids and weighted Lie groupoids of degree one. We take the attitude that the ‘correct definition’ of a \( \mathcal{VB} \)-groupoid is implied by this correspondence. We consider the double structure, that is the pair
of Lie groupoids and the pair of vector bundles together with a collection of not-so-obvious compatibility conditions, as being derived rather than fundamental. This helps motivate our definition of weighted Lie groupoids using homogeneity structures.

**Proposition 3.2.1.** For any weighted Lie groupoid \( \Gamma_k \rightrightarrows B_k \) there is an underlying ‘genuine’ or ‘un-graded’ Lie groupoid \( G \rightrightarrows M \) described by the following surjective groupoid morphism

\[
\begin{array}{c}
\Gamma_k \xrightarrow{h_0} G \\
\downarrow \quad \downarrow \quad \downarrow \quad \downarrow \quad \downarrow \quad \downarrow \\
B_k \xrightarrow{g_0} M
\end{array}
\]

Moreover, if \( \Gamma_k \) is source simply-connected, then so is \( G \).

**Proof.** By construction we have projections \( h_0 : \Gamma_k \rightarrow \Gamma_0 := G \) and \( g_0 : B_k \rightarrow B_0 := M \). Thus \( G \subset \Gamma_k \) and \( M \subset G \) are embedded manifolds. Clearly \( G \) and \( M \) define a (set theoretical) subgroupoid of \( \Gamma_k \rightrightarrows B_k \). As \( (h_t, g_t) \) is a morphism of Lie groupoids for all \( t \in \mathbb{R} \), including zero, it follows that the source map \( \sigma : G \rightarrow M \) is a submersion. Thus we have the structure of a Lie groupoid. Now consider any point \( p \in G \). As \( h_0(p) = p \) the we have an induced retraction map \( \sigma^{-1}(p) \rightarrow \sigma^{-1}(p) \) and thus we have a homomorphisms between the respective fundamental groups. Thus if \( \Gamma_k \) is source simply-connected, then so is \( G \). □

Actually, slightly modifying the above proof, we can derive the groupoid version of the tower of Lie algebroid structures \( (2.14) \).

**Proposition 3.2.2.** If \( \Gamma_k \rightrightarrows B_k \) is a weighted Lie groupoid of degree \( k \), then we have the following tower of weighted groupoid structures of lower order and their morphisms:

\[
\begin{array}{cccc}
\Gamma_k & \xrightarrow{\tau_k} & \Gamma_{k-1} & \xrightarrow{\tau_{k-1}} & \cdots & \xrightarrow{\tau_2} & \Gamma_1 & \xrightarrow{\tau_1} & G \\
\downarrow \quad \downarrow \quad \downarrow \quad \downarrow \quad \downarrow \quad \downarrow \quad \downarrow \quad \downarrow \quad \downarrow \\
B_k & \xrightarrow{\pi_k} & B_{k-1} & \xrightarrow{\pi_{k-1}} & \cdots & \xrightarrow{\pi_2} & B_1 & \xrightarrow{\pi_1} & M
\end{array}
\]

In particular, \( \Gamma_1 \rightrightarrows B_1 \) is a VB-groupoid.

### 3.3 Examples of weighted Lie groupoids

Some examples of weighted Lie groupoids following adaptation of the standard examples include:

**Example 3.3.1.** All graded bundles can be considered as weighted Lie groupoids over themselves by taking all the structure maps to be the identity. This leads to the notion of a weighted unit Lie groupoid.

**Example 3.3.2.** Just as Lie groups are examples of Lie groupoids (over a single point), we can consider weighted Lie groups of degree \( k \) which are Lie groups \( G_k \) equipped with a compatible homogeneity structure of degree \( k \). The compatibility condition is simply \( h_0(g \circ h) = h_0(g) \circ h_0(h) \) for all elements \( g, h \in G_k \).

**Example 3.3.3.** If \( F_k \rightrightarrows M \) is a graded bundle of degree \( k \), then we can construct the weighted pair groupoid in the obvious way; \( F_k \times F_k \rightrightarrows F_k \). Underlying this is the ‘genuine’ pair groupoid \( M \times M \rightrightarrows M \).

**Example 3.3.4.** Let \( G \rightrightarrows M \) be a Lie groupoid. Then associated with this is the higher tangent Lie groupoid \( T^k G \rightrightarrows T^k M \), which is naturally a weighted Lie groupoid and is formed by applying the higher tangent functor of order \( k \) to the structure maps of \( G \rightrightarrows M \). Clearly the initial Lie groupoid is the ‘genuine’ \( G \) groupoid underlying the higher tangent Lie groupoid.

**Example 3.3.5.** As already commented on, VB-groupoids are weighted Lie groupoids of degree 1.

**Example 3.3.6.** Let \( (G_t, h) \) be a weighted Lie group and \( (F_k, g) \) be a graded bundle. We assume that \( G_t \) acts on \( F_k \). Then we can construct the weighted action Lie groupoid as follows; \( G_t \times F_k \rightrightarrows F_k \), where the source and target maps are given by

\[
\mathcal{S}(g, x) = x, \quad \mathcal{T}(g, x) = g \cdot x,
\]
and the (partial) multiplication being
\[(h, y) \circ (g, x) = (hg, x).\]

We define \(\hat{h} := (h, g)\) as the homogeneity structure on the Lie groupoid. Compatibility with the source map and partial multiplication is automatic from the definition of a homogeneity structure, but compatibility with the target map requires the natural condition \(g_t(g \cdot x) = (hg) \cdot (tg x)\). Thus we will define a weighted action Lie groupoid via the construction of an action Lie groupoid, with the addition of compatible homogeneity structures as described above.

**Example 3.3.7.** Any \(\mathcal{GL}\)-bundle \((D_k, \hat{h}, \hat{l})\) can be considered as a weighed Lie groupoid in the following way. The base is defined as \(B_{k-1} := \hat{1}_0(D_k)\) and the source and target maps are set to the projection \(s = t = \hat{1}_0\). Thus, the \(s\)-fibres have the structure of graded spaces c.f. \([11]\) (i.e. graded bundles over a point). The partial multiplication is just the addition in the \(s\)-fibres. The compatibility of the Lie groupoid and graded bundle structures follows directly from the definition of a \(\mathcal{GL}\)-bundle.

### 4 Lie theory for weighted groupoids and algebroids

We now turn our attention to the Lie theory relating weighted Lie groupoids and weighted Lie algebroids. The differentiation of a weighted Lie groupoid produces rather naturally a weighted Lie algebroid. One can use the standard construction here, just taking a little care with the weights. The integration of a weighted Lie algebroid to a weighted Lie groupoid also follows via the standard constructions, again taking care with the graded structure. We will not address the full question of global integrability, rather we will assume integrability as a Lie algebroid and show that the weighted structure is naturally inherited.

#### 4.1 Differentiation of weighted Lie groupoids

It is clear that as a Lie groupoid a weighted Lie groupoid always admits a Lie algebroid associated with it following the classical constructions. The question is if the associated Lie algebroid is in fact a weighted Lie algebroid?

**Theorem 4.1.1.** If \(\Gamma_k \rightrightarrows B_k\) is a weighted Lie groupoid of degree \(k\) with respect to a homogeneity structure \(h\) on \(\Gamma_k\), then \(A(\Gamma_k) \rightarrow B_k\) is a weighted Lie algebroid of degree \(k + 1\) with respect to the homogeneity structure \(\hat{h}\) defined by
\[
\hat{h}_t = (h_t) = \text{Lie}(h_t). \tag{4.1}
\]

**Proof.** We need only follow the classical constructions taking care of the weight as we proceed. In particular, we need only show that \(A(\Gamma_k)\) has the structure of a \(\mathcal{GL}\)-bundle and that the corresponding Lie algebroid brackets are of weight \(-(k+1)\).

1. As \(A(\Gamma_k) := \ker(\mathcal{T}_x|_{B_k})\), it is clear that as a subbundle of \(T\Gamma_k\) that we have the structure of a \(\mathcal{GL}\)-bundle. The degree \(k\) homogeneity structure \(\hat{h}\) is inherited from the tangent lift of the homogeneity structure on \(\Gamma_k\) and the degree 1 homogeneity structure is inherited from the natural one related to the vector bundle structure of tangent bundles. In other words, \(\hat{h}_t = (h_t)'\) is the ‘differential’ of \(h\).

2. Sections of weight \(r\) are by our definition functions on \(A(\Gamma_k)^*\) of bi-weight \((r - 1, 1)\), see section \([2]\). Thus, associating sections with right invariant vector fields requires a shift in the weights of \((-k, -2)\), which comes from associating momenta with derivatives i.e. use weighted principle symbols. Thus, the prolongation of a section of weight \(r\) to a left invariant vector field is a vector field of bi-weight \((r - 1 - k, -1)\). Thus if we take the Lie bracket of two sections of weight \(r_1\) and \(r_2\) as right invariant vector fields the resulting will be a right invariant vector field of weight \((r_1 + r_2 - 2 - 2k, -1)\). Now upon restriction and ‘shifting back’ to functions on \(A(\Gamma_k)^*\), the resulting section is of bi-weight \((r_1 + r_2 - 1 - (k + 1), 1)\). Thus the Lie algebroid bracket carries weight \(-(k+1)\).

\[\square\]

Theorem 4.1.1 tells us that weighted groupoids are the objects that integrate weighted algebroids, but of course it does not tell us that we can actually (globally) integrate weighted Lie algebroids. As a ‘corollary’ we see that \(\mathcal{VB}\)-groupoids are the objects that integrate \(\mathcal{VB}\)-algebroids.
Example 4.1.2. The weighted Lie algebroid associated with the weighted pair Lie groupoid $F_k \times F_k \rightrightarrows F_k$ is the tangent bundle $TF_k$.

Example 4.1.3. The $k$-th order tangent bundle of a Lie groupoid $T^k G$ naturally comes with the structure of a weighted Lie groupoid over $T^k M$. The associated Lie algebroid is $A(T^k G) \simeq T^k A(G)$, see [18] for details. From [2] we know that $T^k A(G)$ is a weighted Lie algebroid.

Proposition 4.1.4. The Lie functor restricts to the subcategories of weighted Lie groupoids and weighted Lie algebroids, i.e.

$$\xymatrix{ \text{wGrpd} \ar[r]^-{\text{Lie}} & \text{wAlgd} }$$

**Proof.** This follows from Theorem 4.1.1 and the fact that both weighted Lie groupoid and weighted Lie algebroid morphisms intertwine the respective actions of the homogeneity structure. \qed

4.2 Integration of weighted Lie algebroids

We will not address the full problem of integration of Lie algebroids here, one should consult Cranic & Ferandes [5] for details of the obstruction to (global) integrability. We remark though, that passing to the world of differentiable stacks and the notion of a Weinstein groupoid all Lie algebroids are integrable [34], though in this work we will strictly stay in the world of Lie groupoids. The question we address is not one of the integrability of weighted Lie algebroids as Lie algebroids, but rather if they integrate to weighted Lie groupoids. That is, does the homogeneity structure on the weighted Lie algebroid integrate to a homogeneity structure on the associated source simply-connected Lie algebroid such that we have the structure of a weighted Lie groupoid?

**Theorem 4.2.1.** Let $D_{k+1} \to B_k$ be a weighted Lie algebroid of degree $k+1$ with respect to a homogeneity structure $\hat{h}$ and $\Gamma_k$ its source simply-connected integration groupoid. Then $\Gamma_k$ is a weighted Lie groupoid of degree $k$ with respect to the homogeneity structure $h$ uniquely determined by (4.1).

**Proof.** A weighted Lie algebroid together with a homogeneity structure $\hat{h}_t : D_{k+1} \to D_{k+1}$ that is for $t \neq 0$ a Lie algebroid automorphisms and for $t = 0$ a morphisms to the underlying non-graded Lie algebroid. Thus we can use Lie II to uniquely integrate $\hat{h}_t$ (for a given $t$) to a Lie groupoid morphism

$$h_t : \Gamma_k \to \Gamma_k,$$

such that $(h_t)' = \hat{h}_t$. The uniqueness of the integration of Lie algebroid morphisms together with the functorial properties of differentiating Lie groupoids, namely $(h_t \circ h_s)' = h_t' \circ h_s'$, implies that $h : \mathbb{R} \times \Gamma_k \to \Gamma_k$ is a homogeneity structure. The the degree of the homogeneity structure similarly follows from the properties of the Lie functor. \qed

Because $A(h_0(\Gamma_k)) = \hat{h}_0(D_{k+1})$, it is clear that the integrability of $D_{k+1} \to B_k$ as a Lie algebroid implies that $A \to M$, where $A = \hat{h}_0(D_{k+1})$ is also integrable as a Lie algebroid. The converse is not true and examples of VB-algebroids with integrable base Lie algebroids for which the total Lie algebroid is not integrable exist, see [1, 4].

5 Weighted Poisson-Lie groupoids and their Lie theory

Following our general ethos that we can construct weighted versions of our favorite geometric structures by simply including a compatible homogeneity structure, we now turn to the notion of weighted Poisson-Lie groups and weighted Lie bi-algebroids. As the propositions in this section follow by mild adaptation of standard proofs by including weights into considerations, we will not generally present details of the proofs.

5.1 Weighted Poisson-Lie groupoids

**Definition 5.1.1.** A weighted Poisson–Lie groupoid $(\Gamma_k, \Lambda)$ of degree $k$ is a Poisson–Lie groupoid equipped with a multiplicative homogeneity structure $\hat{h} : \mathbb{R} \times \Gamma_k \to \Gamma_k$ of degree $k$, such that the Poisson structure is of weight $-k$. 
Recall that a Poisson–Lie groupoid is a Lie groupoid equipped with a multiplicative Poisson structure; this means that
\[
\text{graph(mult)} = \{ (g, h, g \circ h) | g(h) = I(h) \}
\]
is coisotropic inside \((\Gamma_k \times \Gamma_k, x \Gamma_k, \Lambda \oplus \Lambda \ominus \Lambda)\). The associated Poisson bracket on \(C^\infty(\Gamma_k)\) is of weight \(-k\). Weighted Poisson–Lie groupoids should be thought of as the natural generalisation on \(PVB\)-groupoids as first defined by Mackenzie [23]. A \(PVB\)-groupoid is a \(VB\)-groupoid equipped with a compatible Poisson structure.

An alternative, yet equivalent and illuminating way to view weighted Poisson–Lie groupoids is as follows. Let \((G, \Lambda)\) be a Lie groupoid equipped with a Poisson structure, we will temporarily forget the graded structure and place no conditions on the Poisson structure. Associated with the Poisson structure is the fibre-wise map
\[
\Lambda^\# : T^*G \to TG.
\]  
(5.1)
This fibre-wise map is of course completely independent of the groupoid structure on \(G\). Note, however, that if \(G\) is a Lie groupoid, then both \(T^*G \rightrightarrows \Lambda^*(G)\) and \(TG \rightrightarrows TM\) are naturally Lie groupoids [23]. Then one can then define a Poisson–Lie groupoid as a Lie groupoid equipped with a Poisson structure such that the induced map \(\Lambda^\#\) is a morphism of Lie groupoids.

The only extra requirement for the case of a weighted Poisson–Lie groupoid is that \(\Lambda^\# : T^*\Gamma_k \to T\Gamma_k\) must be a morphisms of double graded bundles, and this forces the Poisson structure to be of weight \(-k\). Furthermore note that \(T^*\Gamma_k\) and \(T\Gamma_k\) are both \(\mathcal{GL}\)-bundles, c.f. Section [2].

**Example 5.1.2.** Rather trivially, any weighted Lie groupoid of degree \(k\) is weighted Poisson–Lie groupoid of degree \(k\) when equipped with the zero Poisson structure.

**Example 5.1.3.** Any Poisson–Lie groupoid can be considered as a weighted Poisson–Lie groupoid of degree 0 by equipping it with the trivial homogeneity structure. Lie groups equipped with multiplicative Poisson structures are specific examples.

**Example 5.1.4.** Consider a graded bundle of degree \(k\) equipped with a Poisson structure of weight \(-k\), \((F_k, \Lambda)\). The pair groupoid \(F_k \times F_k \rightrightarrows F_k\) is a weighted Poisson–Lie groupoid of degree \(k\) if we equip \(F_k \times F_k\) with the ‘difference’ Poisson structure.

**Example 5.1.5.** Consider a Poisson–Lie groupoid \((\mathcal{G} \rightrightarrows M, \pi)\), which we can consider as a trivial weighted Poisson–Lie groupoid. Recall that \(T^k\mathcal{G} \rightrightarrows T^kM\) is a weighted Lie groupoid of degree \(k\). Furthermore, in [13] it was shown that the higher tangent lift of a multiplicative Poisson structure is a multiplicative Poisson structure itself. By inspection we see that Poisson structure lifted to the \(k\)-th order tangent bundle \(\Lambda := d_{\mathcal{L}}^{k}\pi\) is of weight \(-k\), with respect to the natural homogeneity structure on the higher tangent bundle. Thus \((T^k\mathcal{G} \rightrightarrows T^kM, d_{\mathcal{L}}^{k}\pi)\) is a weighted Poisson–Lie groupoid of degree \(k\). This example we consider as the archetypal weighted Poisson–Lie groupoid.

## 5.2 Weighted Lie bi-algebroids

Follow Roytenberg [32], Voronov [36] and Kosmann-Schwarzbach [19] we are lead to the following definition.

**Definition 5.2.1.** A pair of weighted Lie algebroids \((D_k, D^*_k)\) both of degree \(k\) is a **weighted Lie bi-algebroid** if and only if the odd Hamiltonians \(Q_{D_k}\) and \(S_{D^*_k}\) on \(T^*(\Pi D_k)\) of weight \((k-1,2,1)\) and \((k-1,1,2)\), respectively, Poisson commute.

Let us employ homogeneous local coordinates
\[
\left( \begin{array}{c}
(x_u^0, \theta^I_{u+1}, p^K_{u+2}, \chi^J_{u+1}) \\
(u,0,0) \\
(u,1,0) \\
(u,1,1) \\
(u,0,1)
\end{array} \right),
\]
(5.2)
on \(T^*(\Pi D_k)\). In these homogeneous coordinates we have
\[
Q = \theta^I_{u-u'+1}Q^I_{u'}(x)p^K_{u+1-u} + \frac{1}{2}\theta^I_{u-u'+1}\theta^K_{u-u'+1}Q^K_{I_{(u')}}(x)\chi^I_{u-k},
\]
\[
S = \chi^{u-u'+1}Q^I_{u'}(x)p^K_{u+1-u} + \frac{1}{2}\chi^{u-u'+1}\chi^K_{I_{(u')}}(x)\theta^I_{u-k}. 
\]
Since we have a Schouten structure here of tri-weight \((k - 1, 1, 2)\), we have a graded fibre-wise map

\[
S^\#: T^*(\Pi D_k) \longrightarrow \Pi T(\Pi D_k),
\]
given in local coordinates by

\[
(S^#)^* dx^\alpha_{u+1} = \frac{\partial S}{\partial p_{\alpha+1-u}}, \quad (S^#)^* d\theta^I_{u+2} = \frac{\partial S}{\partial \chi^I_{u-1}},
\]
where we have employed homogeneous local coordinates

\[
\left(\begin{array}{c}
\begin{array}{c}
\begin{array}{c}
(x^\alpha_{u}), \quad (\theta^I_{u+1}), \quad dx^\beta_{u+1}, \quad d\theta^J_{u+2}, \quad
\end{array} \\
(u,0), (u,1), (u,0), (u,1)
\end{array}
\end{array}\right),
\]
on \(\Pi T(\Pi D_k)\).

**Proposition 5.2.2.** Let \((D_k, D^*_k)\) be a weighted Lie bi-algebroid of degree \(k\). The fibre-wise map \(S^#\) is a graded morphisms of \(Q\)-manifolds

\[
(T^*(\Pi D_k), Q_0 := \{Q, \cdot\}) \longrightarrow (\Pi T(\Pi D_k), L_Q = [d, i_Q]).
\]

**Proof.** It follows via direct computation and so we omit details. \(\Box\)

**Remark 5.2.3.** The above proposition holds for general QS-manifolds and the additional gradings play no critical role. In fact, we do not need a Schouten structure, but just an odd quadratic Hamiltonian such that \(L_Q S := \{Q, S\} = 0\).

**Example 5.2.4.** If \((A, A^*)\) is a Lie bi-algebroid, then \((T^k A, T^k A^*)\) is a Lie bi-algebroid of degree \(k + 1\). See for details [18], although the authors do not make mention of the graded structure.

**Example 5.2.5.** Consider a weighted Lie algebroid \(D_k\) of degree \(k\) together with an even function \(P \in C^\infty(\Pi D_k^1)\) of bi-weight \((k - 1, 2)\) such that \([P, P] = 0\), where the bracket is the Schouten bracket encoding the Lie algebroid structure. Such functions we consider as Poisson structures on weighted Lie algebroids. Then, following well-known classical results, \((D_k, D^*_k)\) is a weighted Lie bi-algebroid of degree \(k\). This example is the weighted version of a triangular Lie bi-algebroid. As a canonical example, \((T(T^{k-1} M), T^*(T^{k-1} M))\) is a weighted Lie bi-algebroid of degree \(k\). The homological vector field is supplied by the de Rham differential on \(\Pi T(T^{k-1} M)\) and the Schouten structure is that associated with the canonical Schouten bracket on \(\Pi T^*(T^{k-1} M)\).

### 5.3 The Lie theory of weighted Poisson-Lie groupoids and weighted Lie bi-algebroids

It is well-known that the infinitesimal object associated with a Poisson–Lie groupoid is a Lie bi-algebroid. Let us quickly sketch the association of a Lie bi-algebroid with a Poisson–Lie groupoid. The construction of the underlying Lie algebroid is as standard, we only need to show how the appropriate Schouten structure is generated and that it carries the correct weight. With this in mind let us outline the classical construction.

It can be shown that there are two natural isomorphisms

\[
\Pi \theta : \Pi A(T^* G) \longrightarrow T^*(\Pi A(G)),
\]
\[
\Pi j : \Pi T(\Pi A(G)) \longrightarrow \Pi A(TG),
\]
which follow from application of the parity reversion functor to the standard non-super isomorphisms (see [24, 25] and [18], where the higher tangent versions are also discussed). Let \((G, \Lambda)\) be a Poisson–Lie groupoid, then as we have \(\Lambda^# : T^* G \rightarrow TG\), we also have the ‘superised’ version:

\[
\Pi(\Lambda^#') : \Pi A(T^* G) \rightarrow \Pi A(TG).
\]

Furthermore, the above gives rise to a Schouten structure on \(\Lambda^#\) viz

\[
\Pi(\Lambda^#') := \Pi j \circ S^# \circ \Pi \theta,
\]
where \( S^\# : T^*(\Pi A(G)) \to \Pi T(\Pi A(G)) \). One now only has to check the weight when dealing with the weighted versions.

In the other direction, it is also well-know that an integration procedure for passing from Lie bialgebroids to Poisson–Lie groupoids. Using Lie’s second theorem one can show that if \((A, A^*)\) is a Lie bialgebroid and \(G \rightrightarrows M\) is the source simply-connected Lie groupoid integrating \(A \to M\), then there exists a unique Poisson structure on \(G\) such that \((G, A)\) is a Poisson–Lie groupoid integrating \((A, A^*)\). Again, it is straightforward to check the weights when dealing with the weighted versions. We are lead to the following proposition.

**Proposition 5.3.1.** There is a canonical correspondence between weighted Poisson–Lie groupoids of degree \(k\) and (integrable) weighted Lie bialgebroids of degree \(k + 1\).

### 5.4 The Courant algebroid associated with weighted Lie bialgebroids

Now let us ‘collapse’ the tri-weight on \(T^*(\Pi D_k)\) to a bi-weight by taking the sum of the last two weight vector fields. Then, the Hamiltonian vector field

\[
Q_\lambda := \{Q + \lambda S, \bullet\} \in \text{Vect}(T^*(\Pi D_k))
\]

is of bi-weight \((0, 1)\). Here we take \(\lambda \in \mathbb{R}\) to be some free parameter (carrying no weight) and so we have a pencil of such vector fields. Clearly \(Q_\lambda\) is a homological vector field. Moreover, as \(Q_1\) is a Hamiltonian vector field its Lie derivative annihilates the canonical symplectic structure on \(T^*(\Pi D_k)\). Note that the canonical symplectic form has natural bi-weight \((k - 1, 2)\). Thus, following Roytenberg [32], we have objects that deserve to be called weighted Courant algebroids of degree \(k\).

**Theorem 5.4.1.** Via the above construction, if \((D_k, D^*_k)\) is a weighted Lie bi-algebroid of degree \(k\), then \(T^*(\Pi D_k)\) naturally has the structure of a weighted Courant algebroid of degree \(k + 1\).

**Example 5.4.2.** The \(k = 1\) case is just that of the exact Courant structure associated with a standard Lie bi-algebroid. The case of \(k = 2\) gives an example of a VB-Courant algebroid.

**Example 5.4.3.** As any weighted Lie algebroid \(D_k\) can be considered as a weighted Lie bi-algebroid with the trivial structure on the dual bundle, \(T^*(\Pi D_k)\) can be considered as a weighted Courant algebroid with the obvious homological vector field.

**Example 5.4.4.** If we take \(D_k = T(T^{k-1}M)\) then we have the natural structure of a weighted Courant algebroid given in local coordinates as

\[
Q = \{\theta^u + p^k_{\alpha+1} \alpha^1 - u, \bullet\} = \theta^u_{\alpha+1} \frac{\partial}{\partial x^u} + p^u_{\alpha+1} \frac{\partial}{\partial x^u} \in \text{Vect}(T^*(\Pi T(T^{k-1}M))).
\]

This example should be considered as an natural generalisation of the canonical Courant algebroid on the generalised tangent bundle \(TM \oplus T^*M\), which is a substructure of \(T(T^*M)\).

To uncover the natural pairing, bracket and anchor structure, first note that \(\Pi D_k \times D^{*1}_{k-1} \Pi D^*_k\) is a quotient supermanifold of \(T^*\Pi D_k\) defined (locally) by projecting out the coordinates \(p^u_{\alpha+1}\). Thus we will naturally identify functions on \(T^*(\Pi D_k)\) of bi-weight \((r - 1, 1)\) as homogeneous sections of the vector bundle \(D_k \oplus D^*_k = D^{\alpha}_{k+1} \oplus D_{k-1}^*\) of degree \(r\), up to a shift in the Grassmann parity. In the homogeneous coordinates introduced above any homogeneous section of degree \(r\) is of the form

\[
\sigma_r = s^I_{r - u - 1}(x) \chi^u_I + \theta^I_{u+1} s^r_{u-1}(x).
\]

The natural pairing between sections, that is a fibre-wise pseudo-Riemannian structure on \(D_k \oplus D^*_k\) with the Poisson bracket on \(T^*(\Pi D_k)\); \n
\[
\langle \sigma^1, \sigma^2 \rangle = \{\sigma^1, \sigma^2\} \in C^\infty(B_{k-1}),
\]

and thus the pairing carries bi-weight \((-k + 1, -2)\), or we can think of the total weight as \(-k - 1\). The fact that we have identified homogeneous sections with particular odd functions on \(T^*(\Pi D_k)\) does not effect the identification of the metric structure and the Poisson structure; everything is linear and so the parity reversion does not add any real complications here. Let us simplify notation slightly and define \(\Theta_\lambda := Q + \lambda S\). Then the derived bracket, given by

\[
\llbracket \sigma^1, \sigma^2 \rrbracket_\lambda := \{\sigma^1, \Theta_\lambda\}, \sigma^2\}
\]

and thus the pairing carries bi-weight \((-k + 1, -2)\), or we can think of the total weight as \(-k - 1\). The fact that we have identified homogeneous sections with particular odd functions on \(T^*(\Pi D_k)\) does not effect the identification of the metric structure and the Poisson structure; everything is linear and so the parity reversion does not add any real complications here. Let us simplify notation slightly and define \(\Theta_\lambda := Q + \lambda S\). Then the derived bracket, given by

\[
\llbracket \sigma^1, \sigma^2 \rrbracket_\lambda := \{\sigma^1, \Theta_\lambda\}, \sigma^2\}
\]
carries bi-weight \((-k + 1, -1)\) (so the total weight \(-k\)) similarly to the case of a weighted Lie algebroid.

It is closed on functions of bi-degree \((k - 1, 1)\), so sections of the vector bundle \(D_k \oplus D_k^*\) of degree \(k\).

The latter is the ‘higher’ analog of the Courant–Dorfman bracket, which is not a Lie bracket, but rather a Loday (Leibniz) bracket. The anchor is then defined as

\[
\rho_\lambda : \text{Sec}(D_k \oplus D_k^*) \to \text{Vect}(B_{k-1})
\]

\[
\rho_\lambda(\sigma)[f] := \{\{\sigma, \Theta_\lambda\}, f\},
\]

for all \(f \in C^\infty(B_{k-1})\).

The example of a weighted Courant algebroid naturally associated with a weighted Lie bi-algebroid leads us to the following general definition.

**Definition 5.4.5.** A *weighted Courant algebroid of degree \(k\) consists of the following data:

1. A double graded supermanifold \((\mathcal{M}, h, l)\) of bi-degree \((k - 1, 2)\) such that \((\mathcal{M}, l)\) is an \(N\)-manifold (the Grassmann parity of homogeneous coordinates is determined by \(l\));

2. An even symplectic form \(\omega\) on \(\mathcal{M}\) of bi-degree \((k - 1, 2)\);

3. An odd function \(\Theta \in C^\infty(\mathcal{M})\) of bi-degree \((k - 1, 3)\), such that \(\{\Theta, \Theta\}_\omega = 0\), where the bracket is the Poisson bracket induced by \(\omega\).

The corresponding derived bracket

\[
[\sigma^1, \sigma^2]_\Theta := \{\{\sigma^1, \Theta\}_\omega, \sigma^2\}_\omega,
\]

is closed on functions of bi-degree \((k - 1, 1)\) (so functions of total degree \(k\)), defining the higher analog of the Courant-Dorfman bracket.

In other words, following our ethos, a weighted Courant algebroid is a Courant algebroid with an additional compatible homogeneity structure.

### 5.5 Remarks on contact and Jacobi groupoids

The notion of a *weighted symplectic groupoid* is clear: it is just a weighted Poisson groupoid with an invertible Poisson, thus symplectic, structure. By replacing the homogeneity structure, i.e. an action of the monoid \(\mathbb{R}\) of multiplicative reals, with a smooth action of its subgroup \(\mathbb{R}^\times = \mathbb{R} \setminus \{0\}\), one obtains a principal \(\mathbb{R}^\times\)-bundle in the category of symplectic (in general Poisson) groupoids. We get in this way the ‘proper’, in our belief, definition of a contact (resp. Jacobi) groupoid.

This belief is based on the general and well-known *credo*, presented e.g. in [12], that the geometry of contact (more generally, Jacobi) structures on a manifold \(M\) is nothing but the geometry of ‘homogeneous symplectic’ (resp., ‘homogeneous Poisson’) structures on an \(\mathbb{R}^\times\)-principal bundle \(P \to M\). The word ‘homogeneous’ refers to the fact that the symplectic form (resp., Poisson tensor) is homogeneous with respect to \(\mathbb{R}^\times\)-action. Of course, it is pretty well-known that any contact (resp., Jacobi) structure admits a symplectization (resp., poissonization) and these facts are frequently used in proving theorems on contact and Jacobi structures (see e.g. [29]). However, in [12] the symplectization/poissonization was taken seriously as a genuine definition of a contact (Jacobi) structure. The general *credo* then says that any object related to a contact (Jacobi) structure ought to be considered as the corresponding object in the symplectic (Poisson) category, equipped additionally with an \(\mathbb{R}^\times\)-principal bundle structure, compatible with other structures defining the object. The only problem is what the compatibility means in various cases.

For Lie groupoids (and also Lie algebroids) it is natural to expect that the condition of an \(\mathbb{R}^\times\)-action to be compatible with the groupoid (algebroid) structure is the same as for the action of multiplicative \(\mathbb{R}\), i.e. it consists of groupoid (algebroid) isomorphisms. This is the reason why we comment on contact and Jacobi groupoids here, postponing however the detailed study to a forthcoming paper.

Note only that our definition of a contact groupoid turns out to be equivalent to the definition of Dazord [8]. The first and frequently used definition, presented in [10], is less general and involves an arbitrary multiplicative function, that is due to the fact that in this approach contact bundles are forced to be trivial. Note that very similar idea of using ‘homogeneous symplectic’ manifolds in the context of contact groupoids appears already in [17] in a slightly less general framework of \(\mathbb{R}_+\)-actions.

To finish, we want to stress that our use of the group \(\mathbb{R}^\times\) rather than \(\mathbb{R}_+\) is motivated by the need of including non-trivial line bundles into the picture; there is a nice one-to-one correspondence between
principal $\mathbb{R}^n$-bundles and line-bundles. In this understanding, the contact structure does not need to admit a global contact form and the Jacobi bracket is defined on sections of a line bundle rather than on functions, so it is actually a local Lie algebra in the sense of Kirillov \cite{Kerr} or a Jacobi bundle in the sense of Marle \cite{Marle}. This, in turn, comes from the observation (c.f. \cite[Remark 2.4]{Gracia-Saz}) that the Jacobi bracket is par excellence a Lie bracket related to a module structure, even if the regular module action of an associative commutative algebra on itself looks formally as the multiplication in the algebra. Consequently, allowing nontrivial modules (line bundles) is necessary for the full and correct picture.
