Abstract. Let $K$ be an algebraically closed field. We classify all of the quadratic twisted tensor products $A \otimes B$ in the cases where $(A, B) = (K[x], K[y])$ and $(A, B) = (K[x, y], K[z])$. We determine when a quadratic twisted tensor product of this form is Koszul, and when it is Artin-Schelter regular.

1. Introduction

Let $K$ be an algebraically closed field, and let $A$ and $B$ be associative $K$-algebras. In [13], Cáp, Schichl, and Vanžura introduced a very general notion of product for $A$ and $B$ called a twisted tensor product, denoted $A \otimes B$. (For precise definitions of terminology we refer the reader to Section 2.) Efforts to understand how ring-theoretic and homological properties behave with respect to this product have been the source of several recent papers. In the article [6], we initiated a detailed study of the Koszul property for graded twisted tensor products. The current paper grew out of our efforts to address two problems left unresolved in [6].

Problem 1.1. If $A$ and $B$ are Koszul algebras and $A \otimes B$ is quadratic, must $A \otimes B$ be a Koszul algebra?

Problem 1.2. Classify quadratic twisted tensor products of $K[x]$ and $K[y]$ up to isomorphism (of twisted tensor products).

2010 Mathematics Subject Classification. 16S37, 16W50.

Key words and phrases. Koszul algebras, quadratic algebras, twisted tensor products, Artin-Schelter regular algebras.
Our solutions to these problems are related. By [6 Proposition 5.5], all quadratic twisted tensor products of \( K[x] \) and \( K[y] \) are Koszul. By [6 Theorem 5.3], the same is true if \( K[x] \) or \( K[y] \) is replaced by \( K[x]/\langle x^2 \rangle \) or \( K[x]/\langle y^2 \rangle \). Hence a negative answer to Problem 1.1 would require \( A \otimes B \) to have at least three algebra generators. This requirement is the impetus for our study, and subsequent classification, of graded twisted tensor products of \( K[x, y] \) and \( K[z] \). A significant part of this classification reduces to Problem 1.2.

In [6 Section 6], we partially settled Problem 1.2 but we were unable to handle one case. Our partial result described possible isomorphism types of \( K[x] \otimes K[y] \), in terms of a one-parameter family of algebras. The parameter could take on any value, except the zeros of an interesting family of polynomials related to the Catalan numbers. The appearance of these polynomials motivated us to completely resolve Problem 1.2 which we do in Section 3. Our first result is the following.

**Theorem 1.3** (Proposition 3.1 and Theorem 3.4). Every quadratic twisted tensor product of \( K[x] \) and \( K[y] \) is isomorphic to either \( C(a, b, 0) = K[x, y]/\langle yz - ax^2 - bxy - y^2 \rangle \) or \( C(a, b, 0) = K[x, y]/\langle yz - ax^2 - bxy \rangle \) for some \( a, b \in K \). Moreover,

1. \( C(a, b, 0) \) is a graded twisted tensor product of \( A = K[x] \) and \( B = K[y] \) for any \( a, b \in K \);
2. \( C(a, b, 1) \) is a graded twisted tensor product of \( A = K[x] \) and \( B = K[y] \) if and only if \( a, b \in K \) satisfy \( f_n(a, b) \neq 0 \) for all \( n \geq 0 \).

The \( f_n(t, u) \) are a family of polynomials generalizing the family described in [6 Section 6]. In Proposition 3.6 we classify the algebras \( C(a, b, 0) \) and \( C(a, b, 1) \) up to isomorphism of graded twisted tensor products. We classify the algebras \( C(a, b, 1) \) and \( C(a, b, 0) \) up to isomorphism of graded algebras in Theorem 3.9.

Section 4 is concerned with the classification of graded twisted tensor products of \( A = K[x, y] \) and \( B = K[z] \). The analysis is considerably more complicated than that of Section 3. We describe twisted tensor products \( A \otimes B \) in terms of a graded twisting map \( \tau : B \otimes A \to A \otimes B \). By [6 Theorem 1.2], in the case of quadratic twisted tensor products, it suffices to describe a graded twisting map on the algebra generators:

\[
\tau(zx) = ax^2 + bxy + cy^2 + dxz + eyz + fz^2,
\tau(zy) = Ax^2 + Bxy + Cy^2 + Dzx + Eyz + Fz^2.
\]

Our main results in Section 4 are summarized in the following theorem.

**Theorem 1.4** (Lemma 4.1, Lemma 4.6). A quadratic twisted tensor product of \( A = K[x, y] \) and \( B = K[z] \) is determined, up to isomorphism of twisted tensor products, by a twisting map \( \tau \) of the form

\[
\tau(zx) = ax^2 + bxy + cy^2 + dxz + eyz + fz^2,
\tau(zy) = Ax^2 + Bxy + Cy^2 + Eyz,
\]

where \( e, f, A \in \{0, 1\} \). Moreover, \( \tau \) belongs to one of the following types:

1. (Ore type) \( f = F = 0 \);
2. (Reducible type) \( f = 1, A = 0 \);
3. (Elliptic type) \( f = 1, A = 1, d = -1 \).

Not all combinations of the parameters produce twisted tensor products. For detailed descriptions of parameter restrictions in each case, see Theorems 4.3, 4.10.
and \[4.14\] respectively. The reason for the “reducible” and “elliptic” terminology is due to the fact that, generically, a reducible type algebra has a reducible point scheme and an elliptic type algebra has an elliptic curve as its point scheme. (Here we are considering point schemes as in \([1]\).) We intend to study the non-commutative algebraic geometry of these algebras, and of twisted tensor products in general, in a forthcoming paper.

In \([6, \text{Example 5.4}]\) we presented an example of Koszul algebras \(A\) and \(B\) such that \(A \otimes_T B\) is not Koszul. However, Koszul algebras are necessarily quadratic algebras, and, in the example we provided, the algebra \(A \otimes_T B\) is not quadratic. This motivated Problem \([1.1]\). In Section 5 we consider the Koszul property for the algebras classified in Section 4 and present a family of examples that provide a negative answer to Problem \([1.1]\).

**Theorem 1.5** (Theorem \([5.4]\), Theorem \([5.6]\)). Let \(T\) be a quadratic twisted tensor product of \(K[x,y]\) and \(K[z]\). If \(T\) is Ore type or reducible type, then \(T\) is Koszul. If \(T\) is elliptic type, then \(T\) is Koszul if and only if \(c - (a - 1)(C + a - 1) \neq 0\).

The non-Koszul elliptic type algebras provide examples of non-Koszul quadratic twisted tensor products of Koszul algebras, solving Problem \([1.1]\). These counterexamples seem interesting in their own right, so we also study the Yoneda algebra of the non-Koszul elliptic type algebras. In particular, Theorem \([5.7]\) gives an explicit finite presentation of these algebras, in terms of generators and relations.

The classification of algebras appearing in Theorem \([1.3]\) includes all skew polynomial algebras and the Jordan plane \(K(x,y)/(yx - xy - y^2)\). These are the two-dimensional Artin-Schelter regular algebras. Having classified quadratic twisted tensor products of \(K[x,y]\) and \(K[z]\) in Section 4, we take up the question of Artin-Schelter regularity in Section 6, where we prove the following result.

**Theorem 1.6** (Theorem \([6.2]\)). Let \(T\) denote a quadratic twisted tensor product of \(R = K[x,y]\) and \(S = K[z]\).

1. If \(T\) is an algebra of Ore type, then \(T\) is AS-regular if and only if \(T \cong R[\sigma; \delta]\) where \(\sigma \in \End(R)\) is invertible.
2. If \(T\) is an algebra of reducible type, then \(T\) is AS-regular if and only if \(E \neq 0\) and \(a + d \neq 0\).
3. Assume that \(\text{char } K \neq 2\). If \(T\) is an algebra of elliptic type, then \(T\) is AS-regular if and only if \(c - (a - 1)(C + a - 1) \neq 0\).

Finally, we remark that the graded twisted tensor product \(A \otimes_T B\) defined by a twisting map \(\tau : B \otimes A \to A \otimes B\) and a graded twisted tensor product \(B \otimes_{\tau'} A\) defined by a twisting map \(\tau' : A \otimes B \to B \otimes A\) are not the same, and need not be related in general. However, if \(A = K[x,y]\) and \(B = K[z]\), then \(A \otimes_T B \cong (B \otimes_{\tau' \circ \tau} A)^{op}\) where \(\tau'^{op} = s \tau s\) is a graded twisting map with \(s : A \otimes B \to B \otimes A\) given by \(s(a \otimes b) = b \otimes a\). Thus, by considering opposite algebras, our results characterize all graded twisted tensor products of \(K[x,y]\) and \(K[z]\), in either order.

2. **Preliminaries**

Throughout the paper, let \(K\) denote an algebraically closed field. Tensor products taken with respect to \(K\) are denoted by \(\otimes\). We write \(K^*\) for \(K - \{0\}\).

We work extensively in categories where the objects are graded \(K\)-vector spaces. If \(V\) and \(W\) are \(N\)-graded \(K\)-vector spaces, then \(V \otimes W\) is \(N\)-graded by the Künneth
formula

\[(V \otimes W)_m = \bigoplus_{k+l=m} V_k \otimes W_l.\]

Whenever we refer to \(V \otimes W\) as a graded space, we assume this Küneth grading.

The term \textit{graded algebra} refers to a unital, associative \(K\)-algebra, \(A = \oplus_{n \geq 0} A_n\), that is \textit{connected} \((A_0 = K)\) and generated by finitely many homogeneous elements. These assumptions imply the graded algebras we consider are \(\mathbb{N}\)-graded and \textit{locally finite} \((\dim A_n < \infty \text{ for all } n \geq 0)\). Almost all of the graded algebras in this paper are generated in homogeneous degree 1. If \(A\) is a graded algebra, we denote the (graded) multiplication map \(A \otimes A \rightarrow A\) by \(\mu_A\). The kernel of the canonical graded algebra homomorphism \(A \rightarrow K\) is the graded radical of \(A\), denoted \(A_+ = \bigoplus_{i \geq 0} A_i\).

### 2.1. Twisted tensor products and twisting maps.

Let \(A\) and \(B\) be graded algebras. A \textit{graded twisted tensor product} of \(A\) and \(B\) is a triple \((C, i_A, i_B)\) consisting of a graded algebra \(C\) and injective homomorphisms of graded algebras \(i_A : A \rightarrow C\) and \(i_B : B \rightarrow C\) such that the graded \(K\)-linear map \(A \otimes B \rightarrow C\) given by \(a \otimes b \mapsto i_A(a) i_B(b)\) is an isomorphism of \(K\)-vector spaces.

Suppose that \(\mathcal{T} = (C, i_A, i_B)\) and \(\mathcal{T}' = (C', i'_A, i'_B)\) are two twisted tensor products of \(A\) and \(B\). We say that \(\mathcal{T}\) and \(\mathcal{T}'\) are \textit{isomorphic} if there exist graded algebra isomorphisms \(\alpha : A \rightarrow A', \beta : B \rightarrow B'\) and \(\gamma : C \rightarrow C'\) such that \(\gamma i_A = i'_A \alpha\) and \(\gamma i_B = i'_B \beta\). Note that this notion of isomorphism is stronger than that of algebra isomorphism. Indeed it is possible to have non-isomorphic triples \(\mathcal{T}\) and \(\mathcal{T}'\) where \(C\) and \(C'\) are isomorphic as graded algebras (see Proposition 4.60 and Theorem 4.69).

As shown in [13], the study of twisted tensor products is greatly facilitated by the notion of a twisting map. We adopt the most general graded version for our work below. By a \textit{graded twisting map} we mean a graded \(K\)-linear map \(\tau : B \otimes A \rightarrow A \otimes B\) such that \(\tau(1 \otimes a) = a \otimes 1\) and \(\tau(b \otimes 1) = 1 \otimes b\) and

\[\tau(\mu_B \otimes \mu_A) = (\mu_A \otimes \mu_B)(1 \otimes \tau \otimes 1)(\tau \otimes \tau)(1 \otimes \tau \otimes 1).\]

The condition that \(\tau\) is graded is simply that \(\tau((A \otimes B)\alpha) \subseteq (B \otimes A)\alpha\) for all \(n \geq 0\) with respect to the Küneth grading. It is common in the literature to see the phrase “graded twisting map” refer to the more restrictive condition: \(\tau(B_i \otimes A_j) \subseteq A_j \otimes B_i\) for all \(i, j \geq 0\). Since a graded twisting map \(\tau\) satisfies

\[\tau(B_+ \otimes A_+) \subseteq (A_+ \otimes K) \oplus (A_+ \otimes B_+) \oplus (K \otimes B_+),\]

we call \(\tau\) \textit{one-sided} if either

\[\tau(B_+ \otimes A_+) \subseteq (A_+ \otimes K) \oplus (A_+ \otimes B_+)\]

or

\[\tau(B_+ \otimes A_+) \subseteq (A_+ \otimes B_+) \oplus (K \otimes B_+).\]

The relationship between twisting maps and twisted tensor products was established in the ungraded case in [13] and in the graded case in [6].

**Proposition 2.1.** [6] Proposition 2.3] Let \(A\) and \(B\) be graded algebras. Let \(\tau : B \otimes A \rightarrow A \otimes B\) be a graded \(K\)-linear map. Define \(\mu_\tau : A \otimes B \otimes A \otimes B \rightarrow A \otimes B\) by \(\mu_\tau = (\mu_A \otimes \mu_B)(1 \otimes \tau \otimes 1)\). Then \(\tau : B \otimes A \rightarrow A \otimes B\) is a graded twisting map if and only if \(\mu_\tau\) defines an associative multiplication giving \(A \otimes B\) the structure of a graded algebra.
If $\tau : B \otimes A \to A \otimes B$ is a graded twisting map, we use the notation $A \otimes_{\tau} B$ for the algebra $(A \otimes B, \mu_{\tau})$. Note that the triple $(A \otimes_{\tau} B, i_A, i_B)$, where $i_A : A \to A \otimes B$ and $i_B : B \to A \otimes B$ are the canonical inclusions, is a twisted tensor product of $A$ and $B$. We will abuse notation and also write $A \otimes_{\tau} B$ for this triple.

The ungraded version of the following fundamental result first appeared in \[6\], Proposition 2.4.

**Proposition 2.2.** \[6\] Proposition 2.4] Let $(C, i_A, i_B)$ be a graded twisted tensor product of graded algebras $A$ and $B$. Then there exists a unique graded twisting map $\tau$ such that $(C, i_A, i_B)$ is isomorphic to $A \otimes_{\tau} B$ as graded twisted tensor products of $A$ and $B$.

The graded twisted tensor product $A \otimes_{\tau} B$ can also be identified with a certain quotient of the free product algebra $A \ast B$. As a $K$-vector space

$$A \ast B = \bigoplus_{i \geq 0, \epsilon_1, \epsilon_2 \in \{0, 1\}} A_{\epsilon_1}^i \otimes (B_+ \otimes A_+)_{\epsilon_2} \otimes B_{i-1}^2.$$  

The algebra $A \ast B$ is $\mathbb{N}$-graded by the usual K"{u}nneth grading. Moreover, there are natural inclusions of $A$ and $B$ into $A \ast B$. Define an ideal of $A \ast B$ by

$$I_{\tau} = \langle b \otimes a - \tau(a \otimes b) : a \in A, b \in B \rangle.$$  

By \[6\] Proposition 2.5, we have $A \otimes_{\tau} B \cong (A \ast B)/I_{\tau}$ as graded algebras.

### 2.2. Quadratic twisted tensor products

Let $C$ be a graded algebra that is generated in degree 1, and let $T(C_1)$ denote the tensor algebra on the vector space $C_1$. The algebra $C$ is called **quadratic** if the kernel of the canonical projection $T(C_1) \to C$ is generated in degree 2. Let $\tau : B \otimes A \to A \otimes B$ be a graded twisting map. In \[6\], the authors characterized when the algebra $A \otimes_{\tau} B$ is quadratic in terms of the structure of $\tau$. We briefly recall the relevant definitions to state this result.

If $V$ and $W$ are graded vector spaces and $f : V \to W$ is a graded linear map, we denote the degree $n$ component of $f$ by $f_n$ and define $f_{\leq n} = \bigoplus_{i=0}^n f_i$ and $f_{> n} = \bigoplus_{i>n} f_i$.

We say a graded linear map $t : (B \otimes A)_{\leq n} \to (A \otimes B)_{\leq n}$ is **graded twisting in degree $n$** if $t(1 \otimes a) = a \otimes 1$ and $t(b \otimes 1) = 1 \otimes b$ for all $a \in A_n$ and $b \in B_n$, and

$$t_n(\mu_B \otimes \mu_A) = (\mu_A \otimes \mu_B)(1 \otimes t_{\leq n} \otimes 1)(t_{\leq n} \otimes t_{\leq n})(1 \otimes t_{\leq n} \otimes 1)$$

as maps defined on $(B \otimes B \otimes A \otimes A)_n$. If $t$ is graded twisting in degree $i$ for all $i \leq n$, we say $t$ is graded twisting to degree $n$.

**Definition 2.3.** \[6\] Definition 4.2] A graded twisting map $\tau : B \otimes A \to A \otimes B$ has the **unique extension property** to degree $n$ if, whenever $\tau' : B \otimes A \to A \otimes B$ is a graded linear map that is twisting to degree $n$ such that $\tau_i = \tau'_i$ for all $i < n$, it follows that $\tau_n = \tau'_n$.

The graded twisting map $\tau$ has the **unique extension property** if $\tau$ has the unique extension property to degree $n$ for all $n \geq 3$.

We note that every one-sided graded twisting map has the unique extension property (\[6\] Proposition 5.2).

**Theorem 2.4.** Let $A$ and $B$ be quadratic algebras and let $\tau : B \otimes A \to A \otimes B$ be a graded twisting map. The following are equivalent:
(1) the graded algebra $A \otimes \tau B$ is quadratic,
(2) the graded twisting map $\tau$ has the unique extension property,
(3) the ideal $I_\tau$ of $A \ast B$ is generated in degree 2.

Proof. The equivalence of (1) and (2) is [6, Theorem 1.2]. Statements (1) and (3) are equivalent by [6, Proposition 2.5]. □

When the algebra $A \otimes \tau B$ is quadratic we will refer to it as a quadratic twisted tensor product of $A$ and $B$.

The following result is very helpful in classifying twisted tensor products up to isomorphism.

**Proposition 2.5.** [6, Proposition 2.2] Let $A$ and $B$ be algebras, and let $\alpha : A \to A$ and $\beta : B \to B$ be algebra automorphisms. If $\tau : B \otimes A \to A \otimes B$ is a twisting map, then the map $\tau' : B \otimes A \to A \otimes B$ defined by $\tau' = (\alpha \otimes \beta) \tau (\beta^{-1} \otimes \alpha^{-1})$ is a twisting map. Furthermore, $A \otimes \tau B$ and $A \otimes \tau' B$ are isomorphic as twisted tensor products of $A$ and $B$.

2.3. Koszul algebras. There are many equivalent ways to define the notion of a Koszul algebra, see the book by Polishchuk and Positselski [8]. To conclude this section we state the definition we will use throughout this paper.

A graded algebra $A$ is called Koszul if the trivial module $A/k = A_0 = A/A_+$ admits a graded projective resolution  
$$
\cdots \rightarrow P_3 \rightarrow P_2 \rightarrow P_1 \rightarrow P_0 \rightarrow k \rightarrow 0,
$$
where, for all $i \geq 0$, $P_i$ is generated in degree $i$. It is well-known, see [8] for example, that every Koszul algebra is quadratic.

3. Quadratic twisted tensor products of $k[x]$ and $k[z]$

In this section we classify all of the quadratic twisted tensor products of two polynomial rings of one variable. This completes the work begun in [6, Section 6]; see especially Theorems 6.2, 6.5 and Proposition 6.6 of that paper. We also use this classification in the next section.

Throughout this section we fix the following notation. Let $A = k[x]$, $B = k[z]$, and let $\tau : B \otimes A \to A \otimes B$ be a graded twisting map. Then  
$$
\tau(z \otimes x) = ax^2 \otimes 1 + bx \otimes z + 1 \otimes cz^2
$$
for some $a, b, c \in k$. Let
$$
C = k(x, z)/(zx - ax^2 - bxz - cz^2).
$$
To indicate dependence on the parameters we will also write $C = C(a, b, c)$.

**Proposition 3.1.** If $a = 0$ or $c = 0$, then $\tau$ has the unique extension property, hence $A \otimes \tau B$ is quadratic.

Proof. The hypotheses imply the graded twisting map $\tau$ is one-sided. The result follows from [6, Proposition 5.2] and Theorem 2.4. □

Henceforth we assume $ac \neq 0$. Applying Proposition 2.5 to the automorphism of $B$, $z \mapsto z/c$, there is no loss of generality in assuming $c = 1$. Let  
$$
C = C(a, b) = k(x, z)/(zx - ax^2 - bxz - z^2).
$$
By Theorem 2.4 determining when \( \tau \) has the unique extension property is equivalent to determining when \( C \) is a graded twisted tensor product of \( A \) and \( B \). Note that for the latter to hold, it is necessary that the Hilbert series of \( C \) be \((1 - t)^{-2}\).

**Lemma 3.2.** The Hilbert series of the algebra \( C(a, b) = \mathbb{K}[x, z]/(zx - ax^2 - bxz - z^2) \) is \((1 - t)^{-2}\) unless \( a = 1 \) and \( b = -1 \).

**Proof.** By [8] p. 126, the Hilbert series of \( C(a, b) \) is either \((1 - t)^{-2}\) or the “Fibonacci series” \( \sum_n F_n t^n \), where \( F_0 = 1, F_1 = 2 \) and \( F_{n+2} = F_{n+1} + F_n \) for \( n \geq 0 \). We claim the Hilbert series is \( \sum_n F_n t^n \) if and only if \( a = 1 \) and \( b = -1 \).

To see this, order the generators of \( C \) as \( x < z \), and order monomials using lexicographic order. By the Diamond Lemma (see, for example, [5]), the element

\[
G = (1 + b)zxz + (a - 1)zx^2 + (b^2 - a)x^2z + a(b + 1)x^3
\]

of the free algebra \( \mathbb{K}[x, z] \) is (up to scaling) the only degree 3 element of a Gröbner basis with respect to the chosen monomial order.

It follows that \( \dim C_3 = 5 \) if and only if \( G = 0 \), which happens if and only if \( a = 1 \) and \( b = -1 \). \( \square \)

Next we define some sequences of polynomials that are the key to the rest of the classification problem. Let \( \{ e_n(t, u) \}, \{ f_n(t, u) \}, \{ g_n(t, u) \}, \{ h_n(t, u) \} \) in \( \mathbb{K}[t, u] \) be defined as follows.

\[
e_0(t, u) = 1, \quad f_0(t, u) = 1
\]

\[
e_n(t, u) = u e_{n-1}(t, u) + f_{n-1}(t, u), \quad f_n(t, u) = e_{n-1}(t, u) + f_{n-1}(t, u) \quad n \geq 1
\]

\[
g_n(t, u) = (1 - u)e_n(t, u) - f_n(t, u), \quad h_n(t, u) = -te_n(t, u). \quad n \geq 0
\]

**Lemma 3.3.**

1. For all \( n \geq 0 \), \( f_n(t, -t) = (1 - t)^n \).
2. For all \( n \geq 0 \), the relation

\[
e_nzx^n z = f_nzx^{n+1} + gnx^{n+1} z + h_n x^{n+2}
\]

holds in \( C \), where \( e_n = e_n(a, b), \ f_n = f_n(a, b), \ g_n = g_n(a, b), \) and \( h_n = h_n(a, b) \).
3. If \( f_i(a, b) \neq 0 \) for all \( 1 \leq i \leq n - 1 \), then \( zx^k \in \text{Span}\{x^i z^j : i, j \geq 0\} \subseteq C \) for \( 1 \leq k \leq n \).

**Proof.** From the recursive formulas it is clear that \( e_n(t, -t) = f_n(t, -t) \) for all \( n \geq 0 \). We have \( f_1(t, u) = 1 - t \), so

\[
f_n(t, -t) = -te_{n-1}(t, -t) + f_{n-1}(t, -t) = -tf_{n-1}(t, -t) + f_{n-1}(t, -t) = f_{n-1}(t, -t)(1 - t),
\]

and hence (1) follows by induction.

The relation in (2) holds for \( n = 0 \) by definition of \( C \). Suppose that the relation

\[
e_{n-1}zx^{n-1} z = f_{n-1}zx^n + gn_{n-1}x^{n} z + h_{n-1}x^{n+1}
\]

holds for some \( n \geq 1 \). Multiplying through by \( z \) on the right and using the defining relation of \( C \) yields

\[
e_{n-1}zx^{n-1}(zx - bxz - ax^2) = f_{n-1}zx^n z + gn_{n-1}x^{n} (zx - bxz - ax^2) + h_{n-1}x^{n+1} z.
\]
Next, using the relation \((1 + b)zxz + (b^2 - 1)x^2z + (b + 1)x^3 = 0\); substituting \(zx = ax^2 + bxz + z^2\) results in
\[(1 + b)(ax^2 + bxz + z^2)z + (b^2 - 1)x^2z + (b + 1)x^3 = 0.\]

Considering that the coefficient of \(x^3\) is nonzero we see that this is a nontrivial dependence relation in \(S\). Thus \(C\) is not a twisted tensor product of \(A\) and \(B\). This concludes the case \(f_1 = 0\).
Henceforth we assume $n \geq 2$ is minimal such that $f_n = 0$. Since $f_1 \neq 0$, we have $a \neq 1$. Thus Lemma 3.3(1) implies $b \neq -a$. We claim that $e_n \neq 0$.

Suppose, to the contrary, that $e_n = 0$. Then the recurrence formulas for $f_n$ and $e_n$ give $f_{n-1} = ae_{n-1}$ and $e_{n-1} = -be_{n-1}$. Since $b \neq -a$, we have $e_{n-1} = 0$ and hence $f_{n-1} = 0$, contradicting the minimality of $n$. Thus $e_n \neq 0$.

By Lemma 3.3(2) the relation

$$e_n z x^n z - g_n x^{n+1} z - ae_n x^{n+2} = 0$$

holds in $C$, and since $f_1, \cdots, f_n$ are all nonzero we know that $zx^n \in S$ by Lemma 3.3(3). The coefficient of $x^{n+2}$ in (**) is nonzero, so (**) is a nontrivial dependence relation in $S$. Thus $C$ is not a twisted tensor product of $A$ and $B$.

Noting that under the change of variables $z \mapsto z/c$ employed above, the coefficient of $x^2$ in $\tau(z \otimes x)$ becomes $ac$, we have the following.

**Corollary 3.5.** Let $A = \mathbb{K}[x]$, $B = \mathbb{K}[z]$, and let $\tau : B \otimes A \to A \otimes B$ be a graded twisting map. Let $a, b, c \in \mathbb{K}$ be given by

$$\tau(z \otimes x) = ax^2 \otimes 1 + bx \otimes z + 1 \otimes cz^2.$$  

Then $A \otimes \tau B$ is quadratic unless $f_n(ac, b) = 0$ for some $n \geq 0$.

To end this section we will classify the quadratic graded twisted tensor products of $A = \mathbb{K}[x]$ and $B = \mathbb{K}[z]$ up to: (1) isomorphism of twisted tensor products of $A$ and $B$, and (2) isomorphism of graded algebras.

**3.1. Classification up to isomorphism of graded twisted tensor products.**

Recall that

$$C(a, b, c) = \mathbb{K}(x, z)/(zx - ax^2 - bxz - cz^2).$$

By Corollary 3.3 the algebra $C(a, b, c)$ is a twisted tensor product of $A$ and $B$ with respect to the obvious inclusions of $A$ and $B$ if and only if $f_n(ac, b) \neq 0$ for all $n \geq 0$. In the classification that follows, we assume that $f_n(ac, b) \neq 0$ for all $n \geq 0$.

Above we showed that if $c \neq 0$, then $C(a, b, c) \cong C(ac, b, 1)$ as graded twisted tensor products. Similarly, if $c = 0 \neq a$, the automorphism $x \mapsto x/a$ induces an isomorphism $C(a, b, 0) \cong C(1, b, 0)$. Otherwise, as twisted tensor products of $A$ and $B$, the $(a, b, c)$ are completely rigid in the following sense.

**Proposition 3.6.** If $C(a, b, 1) \cong C(a', b', 1)$ as graded twisted tensor products of $A$ and $B$, then $a = a'$ and $b = b'$. If $C(1, b, 0) \cong C(1, b', 0)$ or $C(0, b, 0) \cong C(0, b', 0)$ as graded twisted tensor products of $A$ and $B$, then $b = b'$.

**Proof.** By definition, any isomorphism of twisted tensor products $\gamma : C(a, b, 1) \to C(a', b', 1)$ must commute with the inclusions. It follows that $\gamma(x) = \alpha x$ and $\gamma(z) = \beta z$ for some $\alpha, \beta \in \mathbb{K}^*$. Considering the defining relations of $C(a, b, 1)$ and $C(a', b', 1)$ makes it evident that $a = a'$ and $b = b'$. An analogous argument holds in the $c = 0$ case.

**3.2. Classification up to isomorphism of graded algebras.** By Proposition 3.6 it suffices to classify the twisted tensor products: $C(a, b, 1)$, $C(1, b, 0)$, and $C(0, b, 0)$ up to isomorphism.

Let $R = \mathbb{K}(x, z)/(f)$, where $0 \neq f$ is homogeneous of degree 2. It is well-known, see for example Exercise 2.4.3 (2)], that $R$ is isomorphic (as a graded algebra) to exactly one of:
respectively. We use the notation of the previous lemma. Proo.

\[
\phi : K[x, z]/(xz - qxz), \text{ for some } q \in K^*;
\]

(ii) \( J(x, z) = K(x, z)/((x - xz - z^2), \text{ (the Jordan plane); } \)

(iii) \( K(x, z)/(xz) \);

(iv) \( K(x, z)/(x^2) \).

We handle the \( c = 0 \) case first.

**Proposition 3.7.** The following graded algebra isomorphisms hold.

1. \( C(1, b, 0) \cong K_0[x, z] \) if \( b \neq 1 \),
2. \( C(0, b, 0) = K_0[x, z] \) if \( b \neq 0 \)
3. \( C(1, 1, 0) = J(x, z) \)
4. \( C(1, 0, 0) \cong K(x, z)/((x) \).

**Proof.** The first isomorphism can be obtained by \( x \mapsto (1 - b)x \) and \( z \mapsto x + z \). The rest are obvious. \( \square \)

To determine the graded algebra isomorphism type of \( C(a, b, 1) \) we use the following result.

**Lemma 3.8.** [Exercise 2.4.3] Let \( R = K(x, z)/(f) \), where \( 0 \neq f \) is homogeneous of degree 2. Write \( f = x\phi(x) + z\phi(z) \), for some unique linear transformation \( \phi : K x \oplus K z \to K x \oplus K z \). If \( \phi(x) = m_{11}x + m_{12}z \) and \( \phi(z) = m_{21}x + m_{22}z \), define a matrix \( M(\phi) = (m_{ij}) \). Then \( R(\phi) \cong R(\phi') \) as graded algebras if and only if there exists an invertible matrix \( N \) such that \( M' = N^t M N \).

**Theorem 3.9.** Suppose that \( C(a, b, 1) \) is a quadratic twisted tensor product of \( A \) and \( B \). In particular, \( (a, b) \) is not a zero of any of the polynomials \( f_a(t, u) \). Then, as graded algebras,

1. \( C(a, -a, 1) \cong K(x, z)/((x) \);
2. \( C(a, -1, 1) \cong K_{-1}[x, z] \);
3. \( \text{if } b \neq -1 \text{ and } 4a - (b - 1)^2 = 0, \text{ then } C(a, b, 1) \cong J(x, z) \);
4. \( \text{if } b \neq -1, a + b \neq 0 \text{ and } 4a - (b - 1)^2 \neq 0, \text{ then } C(a, b, 1) \cong k_q[x, z], \text{ where } q \text{ satisfies } (a + b)q^2 + (2a + b^2 - 1)q + a + b = 0 \).

**Proof.** We use the notation of the previous lemma. For \( k_q[x, z], J(x, z), \) and \( C(a, b, 1) \) we have

\[
M_q = \begin{bmatrix} 0 & -q \\ 1 & 0 \end{bmatrix}, \quad M_J = \begin{bmatrix} 0 & -1 \\ 1 & -1 \end{bmatrix}, \quad \text{and } M_C = \begin{bmatrix} a & b \\ -1 & 1 \end{bmatrix}
\]

respectively.

First, note that \( z^2 - xz - axz + ax^2 = (z - ax)(z - x) \). Since \( C(a, b, 1) \) is quadratic, \( f_1(a, b) \neq 0 \). Thus \( a \neq 1 \) and (1) follows.

To prove (2), (3) and (4) we simply write down an invertible matrix \( N \) and check the condition of Lemma 3.8.

For (2), let

\[
N = \begin{bmatrix} -1 + \sqrt{1 - a} & 0 \\ -\frac{1}{2} \sqrt{1 - a} & 1 \end{bmatrix}
\]

The determinant of \( N \) is \( -\sqrt{1 - a} \), which is nonzero since \( a \neq 1 \), so \( N \) is invertible. It is straightforward to check that \( N^t M_{-1} N = M_C \).
For (3), assume that \( b \neq -1 \) and \( 4a - (b-1)^2 = 0 \). Let \( i \in K \) such that \( i^2 = -1 \). Let 

\[
N = \begin{bmatrix}
\frac{i(d+1)}{i(d^2-1)} & 0 & i \\
\frac{i(d^2-1)}{i(d+1)} & 1 & 0 \\
1 & i & 1
\end{bmatrix}.
\]

Clearly \( N \) is invertible and one checks that \( N^t M_J N = M_C \).

Finally, for (4) assume that \( b \neq -1, a\neq 0 \) and \( 4a - (b-1)^2 \neq 0 \). Suppose that \( q \in K \) satisfies \((a+b)q^2 + (2a+b^2-1)q + a + b = 0\). We claim that \( q \in K - \{0,1,-1\} \).

To see this suppose \( q \in \{0,1,-1\} \). If \( q = 0 \), then \( a+b = 0 \); if \( q = 1 \), then \( 4a - (b-1)^2 = 0 \); if \( q = -1 \), then \( b = -1 \). We conclude that \( q \in K - \{0,1,-1\} \).

Define 

\[
N = \begin{bmatrix}
\frac{1+qB}{1-q} & 1 & \frac{1-q}{1-q} \\
\frac{1-q}{1-q} & 1 & \frac{1-q}{1-q} \\
\frac{1-q}{1-q} & \frac{1-q}{1-q} & \frac{1-q}{1-q}
\end{bmatrix}.
\]

Then \( \det N = -(1+b)/(1+q) \neq 0 \), so \( N \) is invertible and one checks that \( N^t M_q N = M_C \).

\[\square\]

4. Quadratic twisted tensor products of \( K[x,y] \) and \( K[z] \)

Throughout this section, and for the rest of the paper, we fix the notation \( R = K[x,y] \) and \( S = K[z] \). For readability, henceforth, when we write \( T \) is a (quadratic) graded twisted tensor product, we mean \( T \) is a (quadratic) graded twisted tensor product of \( R \) and \( S \). Also, if \( T \) and \( T' \) are graded twisted tensor products and we write \( T \) is isomorphic to \( T' \), then we mean that \( T \) and \( T' \) are isomorphic as graded twisted tensor products of \( R \) and \( S \). The main result of this section is the determination of all of the isomorphism classes of the quadratic twisted tensor products of \( R \) and \( S \). Let \( a, b, c, d, e, f; A, B, C, D, E, F \in K \) and define elements of the tensor algebra \( K(x,y,z) \) (suppressing tensors)

\[
\tau(zx) = ax^2 + bxy + cy^2 + dxz + eyz + fz^2,
\tau(zy) = Ax^2 + Bxy + Cy^2 + Dxz + Eyz + Fz^2.
\]

The problem under consideration is to determine when the algebra

\( T = K(x,y,z)/(zx - \tau(zx), zy - \tau(zy), xy - yx) \)

is a graded twisted tensor product of \( R \) and \( S \) relative to the obvious inclusions \( i_R : R \to T \) and \( i_S : S \to T \). To indicate the dependence of \( T \) on the parameters, we will also use the notation

\( T = T(a, b, c, d, e, f; A, B, C, D, E, F) \).

We begin with a reduction in the number of parameters.

**Lemma 4.1.** If \( T \) is a graded twisted tensor product, then \( T \) is isomorphic to \( T(a', b', c', d', e', f' ; A', B', C', 0, E', 0) \) where \( e', f', A' \in \{0,1\} \). Furthermore, if \( e' = A' = 0 \), then \( C' \in \{0,1\} \), and if \( e' = 1 \), then \( d' = E' \).

**Proof.** We will apply Proposition 2.3 repeatedly to automorphisms of \( R \) and \( S \).

If \( F = 0 \neq f \), applying Proposition 2.3 to the automorphism of \( S \) given by \( z \mapsto f^{-1}z \), we see that \( T \cong T(a', b', c', d', e', 1; A', B', C', D', E', 0) \).
If \( F \neq 0 \), then applying Proposition \[ \ref{prop:automorphism} \] to the automorphism of \( R \) given by \( x \leftrightarrow y \), if necessary, and the automorphism \( z \mapsto f^{-1}z \), we have
\[
T \cong T(a', b', c', d', e', f'; A', B', C', D', E', F').
\]
Then we use the automorphism of \( R \) given by \( x \mapsto x, \ y \mapsto y + F'x \) to see that, without loss of generality, \( F' = 0 \) and \( f' = 1 \).

We have proved that if \( T \) is any twisted tensor product of \( R \) and \( S \), then
\[
T \cong T(a', b', c', d', e', f'; A', B', C', D', E', 0)
\]
for \( f' \in \{0, 1\} \), so we assume henceforth that \( F = 0 \) and \( f \in \{0, 1\} \).

The graded automorphism group of \( R \) is \( \text{GL}_2(\mathbb{K}) \), and since \( \mathbb{K} \) is algebraically closed we choose an automorphism \( P \) of \( R \) so that the matrix \( P \begin{bmatrix} d & e \\ D & E \end{bmatrix} P^{-1} \) is in Jordan normal form. Applying Proposition \[ \ref{prop:automorphism} \] to this automorphism, we have
\[
T \cong T(a'', b'', c'', d'', f; A'', B'', C'', 0, E'', 0)
\]
where \( e' = 0 \) or \( e' = 1 \) and \( d' = E' \). Note that this isomorphism does not affect the coefficients of \( z^2 \). Then if \( A' \neq 0 \), we may rescale \( x \mapsto A'^{-1}x \) to obtain
\[
T \cong T(a'', b'', c'', d'', 0, f; 1, B'', C'', 0, E'', 0).
\]
To complete the proof, if \( e' = A' = 0 \), and \( C' \neq 0 \), we may rescale \( y \mapsto C'^{-1}y \) to obtain
\[
T \cong T(a'', b'', c'', d'', 0, f; 0, B'', 1, 0, E'', 0).
\]

\[ \square \]

We refer to the isomorphism class of Lemma \[ \ref{lem:isomorphism} \] as the \textit{Jordan normal form} of the twisted tensor product \( T \).

Let us first dispense with the case \( f = 0 \). Let \( \sigma \in \text{End}(R) \) be a graded ring endomorphism and let \( \delta \) be a graded left \( \sigma \)-derivation, meaning \( \delta(r_1r_2) = \sigma(r_1)\delta(r_2) + \delta(r_1)r_2 \) for all \( r_1, r_2 \in R \). Then one may construct the \textit{graded (left) Ore extension} \( R[z; \sigma, \delta] \), which is freely generated as an \( R \)-algebra by \( z \), subject to the relations \( zr = \sigma(r)z + \delta(r) \) for \( r \in R \).

**Proposition 4.2.** The algebra \( T \) is a graded twisted tensor product with \( f = F = 0 \) if and only if \( T \) is a graded Ore extension.

**Proof.** Suppose \( \sigma \) is a graded ring endomorphism of \( R \) and \( \delta \) is a graded left \( \sigma \)-derivation. From the relations of \( R[z; \sigma, \delta] \) it is clear that the set \( S = \{ x^iy^jz^k : i, j, k \geq 0 \} \) is a \( \mathbb{K} \)-linear spanning set. Since \( z \) is a free generator and \( \{ x^iy^j : i, j \geq 0 \} \) is a \( \mathbb{K} \)-basis for \( R \), it follows that \( S \) is a \( \mathbb{K} \)-basis for \( R[z; \sigma, \delta] \). Hence the \( \mathbb{K} \)-linear map \( R \otimes S \to R[z; \sigma, \delta] \) given by \( r \otimes z^i \mapsto rz^i \) is an isomorphism, and \( R[z; \sigma, \delta] \) is a graded twisted tensor product. The graded twisting map associated to \( R[z; \sigma, \delta] \) is given by \( \tau (z \otimes r) = \sigma(r) \otimes z + \delta(r) \otimes 1 \), and it follows that \( f = F = 0 \).

Now suppose \( T \) is a graded twisted tensor product of \( R \) and \( S \) with \( f = F = 0 \). Since \( T \) is quadratic, the definitions of \( \tau (z \otimes x) \) and \( \tau (z \otimes y) \) uniquely determine a one-sided graded twisting map \( \tau \) for \( T \) by Theorem \[ \ref{thm:twisting} \]. Since \( \tau \) respects multiplication in \( R \), we have \( \tau (z \otimes r) \in (R \otimes \mathbb{K}z) \oplus (R \otimes \mathbb{K}1_S) \) for all \( r \in R \). Define graded \( \mathbb{K} \)-linear maps \( \sigma, \delta : R \to R \) by \( \tau(z \otimes r) = \sigma(r) \otimes z + \delta(r) \otimes 1_S \). Then for
any $r_1, r_2 \in R$, we have

$$
\sigma(r_1 r_2) \otimes z + \delta(r_1 r_2) \otimes 1_S = \tau(z \otimes r_1 r_2)
$$

$$
= (\mu_R \otimes 1)(1 \otimes \tau)((\sigma(r_1) \otimes z + \delta(r_1) \otimes 1_S) \otimes r_2)
$$

$$
= \sigma(r_1)\sigma(r_2) \otimes z + (\sigma(r_1)\delta(r_2) + \delta(r_1)r_2) \otimes 1_S.
$$

This shows $\sigma$ is a ring endomorphism and $\delta$ is a (left) $\sigma$-derivation. By Theorem 2.4(3), for all $r \in R$, the relations $zi_r(r) = \sigma(i_R(r))z + \delta(i_R(r))$ hold in $T$. Since $T$ is a graded twisted tensor product, $S = \{x^iy^jz^k : i, j, k \geq 0\}$ is a $K$-basis for $T$, thus $T$ is freely generated as an $i_R(R)$-algebra by $z$. Thus $T$ is a graded Ore extension. □

When $T$ is isomorphic to a graded twisted tensor product with $f = F = 0$, we say $T$ is of Ore type.

4.1. The Ore type case. Let $\sigma \in \text{End}(R)$ be the ring endomorphism given by $\sigma(x) = dx + ey$ and $\sigma(y) = Dx + Ey$. Proposition 4.2 shows that to determine which values of the parameters ensure $T$ is a graded twisted tensor product, it suffices to characterize when

$$
\delta(x) = ax^2 + bxy + cy^2, \quad \delta(y) = Ax^2 + Bxy + Cy^2
$$

determine a well-defined left $\sigma$-derivation $\delta : R \to R$. In turn, the definitions in the last display determine a well-defined left $\sigma$-derivation $\delta : R \to R$ if and only if $\delta(xy) = \delta(yx)$, or equivalently if

$$
\sigma(x)\delta(y) + \delta(x)y = \sigma(y)\delta(x) + \delta(y)x,
$$

holds in the ring $R$.

**Theorem 4.3.** Suppose $T$ is an Ore type twisted tensor product in Jordan normal form.

(1) If $e = D = 0$, then one of the following mutually exclusive cases is true:

(i) $d = E = 1$ and $a, b, c; B$ are arbitrary;

(ii) $d \neq 1, E = 1, A = B = C = 0$, and $a, b, c$ are arbitrary;

(iii) $d = 1, E \neq 1, a = b = c = 0$, and $B$ is arbitrary;

(iv) $d \neq 1, E \neq 1, A = c = 0, a = B(d-1)/(E-1), B = C(d-1)/(E-1), C \in \{0, 1\}$ and $B$ is arbitrary.

(2) If $e = 1$ and $d = E$, then one of the following mutually exclusive cases is true:

(i) $d = 1, A = B = C = 0$, and $a, b, c$ are arbitrary;

(ii) $d \neq 1, A = 0, B = a, a = (b - C)(d - 1), c = C/(d - 1), C \in \{0, 1\}$ and $B$ is arbitrary.

**Proof.** For (1), suppose that $e = D = 0$. Equating coefficients in $\sigma(x)\delta(y) + \delta(x)y = \sigma(y)\delta(x) + \delta(y)x$ yields the system of equations

$$
A(d-1) = 0
$$

$$
B(d-1) + a(1-E) = 0
$$

$$
C(d-1) + b(1-E) = 0
$$

$$
c(E-1) = 0.
$$

from which the result follows by considering the possible normal forms and whether $d$ or $E$ equals 1.
The proof of (2) is similar, and is left to the reader. \qed

This completes the classification, up to isomorphism, of twisted tensor products of Ore type.

We now turn our attention to the case where $T$ is a quadratic twisted tensor product in Jordan normal form with $f = 1$. As the associated twisting map is no longer one-sided, this case is more difficult. Surprisingly, as we will show, knowing $\dim T_3 = 10$ is sufficient for proving $T$ is a quadratic twisted tensor product. For this reason, the remainder of this section relies upon a Gröbner basis calculation.

First we record two useful facts. We note that the following does not require that the algebras are graded.

**Proposition 4.4.** Let $A$ and $B$ be (graded) algebras and let $\tau : B \otimes A \rightarrow A \otimes B$ be a (graded) twisting map. Let $i_A : A \rightarrow A \otimes B$ be the natural inclusion. Suppose $y \in A$ is a normal element such that $i_A(y)$ is normal in $A \otimes \tau B$. (In the graded context, also assume $y$ is homogeneous.) Then $\tau$ induces a (graded) twisting map $\tau : B \otimes A/yA \rightarrow A/yA \otimes B$.

**Proof.** Since $y$ is normal in $A$, $(y) = yA$. The assumption that $i_A(y)$ is normal implies that for all $b \in B$ there exists some $b_\tau \in B$ such that $\tau(b \otimes y) = y \otimes b_\tau$. This, together with the fact that $\tau$ respects the multiplication of $A$, yields

$$\tau(B \otimes (y)) = \tau(B \otimes yA) \subseteq yA \otimes B = (y) \otimes B.$$  

The result now follows from [6, Theorem 3.7]. \qed

**Corollary 4.5.** If $T$ is a twisted tensor product in Jordan normal form with $A = 0$ and $f = 1$, then $y$ is normal in $T$ and $(a, d)$ is not a zero of $f_n(t, u)$ for all $n \geq 1$. In particular, $a \neq 1$.

**Proof.** Let $T$ be a twisted tensor product in Jordan normal form with $A = 0$ and $f = 1$. Then $T$ may be presented as

$$\mathbb{K}(x, y, z)/\langle xy - yx, zx - ax^2 - byx - cy^2 - dxz - z^2, zy - Byx - Cy^2 - Eyz \rangle.$$  

It is then clear from this presentation that $y$ is normal in $T$.

Next, note that

$$T/(y) = \mathbb{K}(x, z)/\langle zx - ax^2 - dxz - z^2 \rangle.$$  

By assumption, $T$ has \{ $y^i x^j z^k : i, j, k \geq 0$ \} as a $\mathbb{K}$-basis, so it follows that $T/(y)$ has \{ $x^j z^k : j, k \geq 0$ \} as a $\mathbb{K}$-basis. Hence $T/(y)$ is a twisted tensor product of $\mathbb{K}[x]$ and $\mathbb{K}[z]$. Then Theorem 3.4 implies that $(a, d)$ is not a zero of $f_n(t, u)$ for all $n \geq 1$.

Finally, recall that $f_1(t, u) = 1 - t$, so we have $a \neq 1$. \qed

We briefly recall some terminology and notation for Gröbner basis calculations, loosely following [6].

Let $\mathbb{K}(X)$ be the free algebra on a (finite) set $X$. Fix a total order on $X$ and well-order monomials in $\mathbb{K}(X)$ using degree-lexicographic order. Let $\mathcal{B}$ be a set of homogeneous elements of the form $W - f_W$ where $W$ is a monomial in $\mathbb{K}(X)$ and $f_W \in \mathbb{K}(X)$ such that $f$ is a linear combination of monomials less than $W$. Denote the set of all monomials $W$ such that $W - f_W \in \mathcal{B}$ for some $f_W \in \mathbb{K}(X)$ by $\text{ht}(\mathcal{B})$; this is the set of *high terms* of $\mathcal{B}$. For simplicity, and to suit our purposes,
we assume $\mathcal{B}$ has been chosen so that $W \in \text{ht}(\mathcal{B})$ implies no subword of $W$ is in $\text{ht}(\mathcal{B})$.

If $m$ and $m'$ are monomials and $W - f_W \in \mathcal{B}$, let $r_{mWm'} : \mathbb{K}\langle X \rangle \to \mathbb{K}\langle X \rangle$ be the $\mathbb{K}$-linear map that is the identity on all monomials of $\mathbb{K}\langle X \rangle$ except $r_{mWm'}(mWm') = mf_Wm'$. We refer to the maps $r_{mWm'}$ as reductions. Note that any infinite sequence of reductions applied to an element of $\mathbb{K}\langle X \rangle$ eventually stabilizes, though two such sequences need not result in the same element of $\mathbb{K}\langle X \rangle$. An overlap occurs when there exist monomials $m, m', m''$ and elements $W_1 - f_{W_1}, W_2 - f_{W_2} \in \mathcal{B}$ such that $W_1 = mm'$ and $W_2 = mm''$. An overlap is resolvable if there are sequences of reductions $r$ and $r'$ such that $r(f_{W_1}, m') = r'(m f_{W_2})$.

Consider the graded algebra $R = \mathbb{K}\langle X \rangle / \langle \mathcal{B} \rangle$. If all overlaps of $\mathcal{B}$ in homogeneous degrees $\leq d$ are resolvable, then monomials of degree $\leq d$ that do not contain any element of $\text{ht}(\mathcal{B})$ as a subword form a $\mathbb{K}$-basis for $R_{d \leq d}$. In this case we say $\mathcal{B}$ is a Gröbner basis to degree $d$. If an overlap does not resolve, one may “force” it to resolve by adding to $\mathcal{B}$ a new element $W - f_W$ where $W$ is the largest monomial such that $\lambda(W - f_W) \neq 0$ for some $\lambda \in \mathbb{K}^*$ and any sequence of reductions $r$ that eventually stabilizes on $f_{W_1}C - Af_{W_2}$. Note that adding such elements to $\mathcal{B}$ does not change $R$.

We apply this theory to the algebra $T$ in Jordan normal form. Order the monomials in $\mathbb{K}\langle x, y, z \rangle$ with left lexicographical order determined by $y < x < z$. Let $\mathcal{B} = \{xy - yx, z^2 - (zx - ax^2 - byx - cy^2 - dxz - cyz), z(y - (ax^2 + Byx + Cy^2 + Eyz))\}$.

Under the chosen term order there are two overlaps in degree 3: $z^3$ and $z^2y$. Reducing the differences $(f_{xz})z - z(f_{x^2})$ and $(f_{yz})y - z(f_{zy})$ as much as possible yields the following expressions:

\[
G_1 = (1 + d)zx z + (a - 1)zx^2 - (a - d^2 - eA)x^2 z + (a + ad + bA)x^3 + (b + e)Eyz x \\
+ (eB - deE + 2de - b)yxz + (b + bd + bB + cA + cA E + ac - aeE)yx^2 \\
+ (ceE - b + cE - e^2E + e^2)yz^2 z + (c + cd + bC + eB + cBE - beE + be)yz^2 x \\
+ (cC + cCE - ceE - ce)yz^3,
\]

\[
G_2 = -Azx z^2 - AE x^2 z + (A - dA - AB)x^3 + (E - BE - E^2)y z x \\
- (deE + BE - dE^2)yxz + (B - a - dB - B^2 - AC - ACE + aE^2 - eA)yx^2 \\
- (CE^2 + CE + eE - eE^2)yz^2 z + (C - b - dC - 2BC - BE + bE^2 - eB)yz^2 x \\
- (c + C^2 + C^2 E - eE^2 + eC)yz^3.
\]

**Lemma 4.6.** We have $\dim T_3 = 10$ if and only if $\dim \text{Span}_{\mathbb{K}}\{G_1, G_2\} = 1$. If $T$ is a twisted tensor product in Jordan normal form with $f = 1$, then either

1. $G_2 \neq 0 \neq G_1$ in $\mathbb{K}\langle x, y, z \rangle$ and $(a, d)$ is not a root of any $f_n(t, u)$, or
2. $G_2 \neq 0$, $d = -1$, $A = 1$ and $G_1 = (1 - a)G_2$.

**Proof.** There are 11 monomials of degree 3 in $\mathbb{K}\langle x, y, z \rangle$ that do not contain an element of $\text{ht}(\mathcal{B}) = \{xy, zy, z^2\}$ as a subword. If $G_1 = G_2 = 0$, then $\mathcal{B}$ is a Gröbner basis for $T$ to degree 3 and $\dim T_3 = 11$. If $G_1$ and $G_2$ are linearly independent, then in order for both overlaps $z^3$ and $z^2y$ to resolve, suitable rescalings of both $G_1$ and $G_2$ must be appended to $\mathcal{B}$, implying $\dim T_3 = 9$. The first statement follows.
If $T$ is a twisted tensor product, then the Hilbert series of $T$ is $(1 - t)^{-3}$, hence $\dim T_3 = 10$. If $G_2 = 0$, then $A = 0$, so $(a,d)$ is not a root of any $f_n(t,u)$ by Corollary 4.5. In particular, $a \neq 1$ and thus $G_1 \neq 0$.

If $G_2 \neq 0$, then $G_1 = \lambda G_2$ for some scalar $\lambda$. Since $G_2$ has no $zxz$ term, we must have $d = -1$. Since $T$ is in Jordan normal form, $A \in \{0, 1\}$. We claim $A = 1$. On the contrary, if $A = 0$, then note that

$$G_2 = E(1 - B - E)yxz + E(1 - B - E)yxx + \text{ sum of terms in } \{ y^i x^j z^k \}.$$ 

Since $T$ is a twisted tensor product, the first two terms in the last expression cannot vanish, thus, the high term of $G_2$ is $yxz$. Since $G_1 = \lambda G_2$, it follows that $a - 1 = 0$, contradicting Corollary 4.5. Thus $A = 1$, and the fact that $\lambda = 1 - a$ follows by considering the coefficients of the $zx^2$ terms.

In a forthcoming paper we will study the geometry, in the sense of [1], of twisted tensor products. In the case $f = 1$, $G_2 = 0$, the point scheme of $T$ is reducible; whereas in the case $f = 1$, $G_2 \neq 0$, generically, the point scheme of $T$ is an elliptic curve. We refer to quadratic twisted tensor products (in Jordan normal form) where $f = 1$ and $G_2 = 0$ as reducible and those where $f = 1$ and $G_2 \neq 0$ as elliptic.

We consider the two cases in the following subsections.

4.2. The reducible case, $f = 1, G_2 = 0$. In this subsection we fix

$$T = T(a,b,c,d,e,1; A,B,C,0,E,0)$$

and show that if $G_2 = 0$ and $(a,d)$ is not a root of any $f_n(t,u)$, then $T$ is a quadratic twisted tensor product.

We define a filtration on $T$ following Section 4.2.1 of [4]. Let $V_1 = \mathbb{K} y$ and $V_2 = \mathbb{K} x \oplus \mathbb{K} z$, so $T_1 = V_1 \oplus V_2$. Then the natural identification

$$(T_1)^{\otimes n} \cong \bigoplus_{(i_1,\ldots,i_n) \in \{1,2\}^n} V_{i_1} \otimes \cdots \otimes V_{i_n}$$

endows the tensor algebra $T(T_1)$ with the structure of a $\mathbb{K}$-vector space graded by the ordered monoid $M = \bigcup_{n=0}^{\infty} \{1,2\}^n$ of all tuples with entries in $\{1,2\}$. The set $M$ is a monoid under concatenation of tuples and the left-lexicographic order

$$\emptyset < (1) < (1,1) < (1,2) < (2,1) < (2,2) < \cdots$$

is compatible with concatenation. It is clear that the $M$-grading respects the multiplication in $T(T_1)$. Observe that this is a refinement of the $\mathbb{N}$-grading given by tensor degree.

The filtration naturally associated to this $M$-grading is given by

$$F_{(i_1,\ldots,i_n)} T(T_1) = \bigoplus_{(j_1,\ldots,j_m) \subseteq (i_1,\ldots,i_n)} V_{j_1} \otimes \cdots \otimes V_{j_m}.$$ 

The canonical projection $T(T_1) \to T$ induces a filtration on $T$, and we denote the associated $M$-graded algebra by $\text{gr}_F T$ or just $\text{gr} T$.

There is a canonical $M$-graded algebra homomorphism $T(T_1) \to \text{gr} T$, and we denote the kernel of its restriction to $T_1 \otimes T_1$ by $\mathcal{K}_{\text{lead}}$. Let $T^0 = T(T_1)/(<\mathcal{K}_{\text{lead}}>)$. Noting that $G_2 = 0$ implies $A = 0$, we have

$$T^0 = \mathbb{K}(y,x,z)/\langle zx - ax^2 - dxz - z^2, yx, xy \rangle.$$
Lemma 4.7. Assume $G_2 = 0$ and $(a, d)$ is not a root of any $f_n(t, u)$. Then the algebra $T^\circ$ is Koszul with Hilbert series $H_{T^\circ} = (1 - t)^{-3}$. The set $\{y^j x^i z^k : i, j, k \geq 0\}$ is a $K$-basis for $T^\circ$.

Proof. Let $D = K[x, z]/(zx - ax^2 - dxz - z^2)$ and define a graded twisting map $\rho: D \otimes K[y] \to K[y] \otimes D$ by $\rho(1 \otimes y) = y \otimes 1, \rho(x \otimes 1) = 1 \otimes x, \rho(z \otimes 1) = 1 \otimes z$, and $\rho_{\geq 2} = 0$. Note that $K[y] \otimes D$ and $T^\circ$ are isomorphic as $\mathbb{N}$-graded algebras.

Since $(a, d)$ is not a root of any $f_n(t, u)$, [3, Theorem 6.2] and our results in Section 3 imply that $D = K[x] \otimes_{\sigma} K[z]$ for the obvious twisting map $\sigma$. Thus $T^\circ \cong K[y] \otimes_{\rho} (K[x] \otimes_{\sigma} K[z])$. This shows $\{y^j x^i z^k : i, j, k \geq 0\}$ is a $K$-basis for $T^\circ$ and hence the Hilbert series of $T^\circ$ is $(1 - t)^{-3}$.

Finally, by [3, Theorem 6.2 and Theorem 5.5] we see that $D$ is Koszul. By [6, Theorem 5.3 (2)], $K[y] \otimes_{\rho} D$ is Koszul, hence $T^\circ$ is Koszul. $\square$

Theorem 4.8. If $G_2 = 0$ and $(a, d)$ is not a root of any $f_n(t, u)$, then $T = (T(a, b, c, d, e, 1; A, B, C, 0, E, 0))$ is a quadratic twisted tensor product. Moreover, $T$ is Koszul.

Proof. Since $(a, d)$ is not a root of $f_1(t, u) = 1 - t$, $a \neq 1$ and hence $G_1 \neq 0$. By Lemma 4.6, $\dim T_3 = 10$. As graded vector spaces, $T$ and $gr T$ are isomorphic, so $\dim(gr T)_3 = 10$. Lemma 4.7 gives the Hilbert series of $T^\circ$ as $(1 - t)^3$, so the canonical graded projection $T^\circ \to gr T$ is injective in homogeneous degree 3.

Lemma 4.7 also shows that the algebra $T^\circ$ is Koszul, so by [7, Theorem 4.2.4], the canonical graded projection $T^\circ \to gr T$ is an isomorphism and $T$ is Koszul.

By Lemma 4.7 the algebra $T^\circ$ has a linear basis of the form $\{y^j x^i z^k : i, j, k \geq 0\}$. Since the projection $T^\circ \to gr T$ is an isomorphism, $gr T$ also has this basis, and consequently $T$ does as well. It follows that $T$ is a twisted tensor product. $\square$

We conclude this subsection by recording the solution set of the system of equations determined by setting $G_2 = 0$, and consequently, the parameter values for which $T$ is a twisted tensor product of $R$ and $S$. The following is immediate from the form of the expression $G_2$.

Lemma 4.9. The expression $G_2 = 0$ if and only if $A = 0$ and all of the following hold:

1. $E(1 - B - E) = 0$,
2. $E(1 - d - B + dE) = 0$,
3. $B(1 - d - B) - a(1 - E^2) = 0$,
4. $E(C + CE + e - eE) = 0$,
5. $C(1 - d - 2B - BE) - b(1 - E^2) - eB = 0$,
6. $(1 + E)(-c(1 - E) - C^2) - eC = 0$.

Theorem 4.10. Suppose that $T = T(a, b, c, d, e, 1; A, B, C, 0, E, 0)$ is a quadratic twisted tensor product in Jordan normal form. If $G_2 = 0$, then $A = 0$, $(a, d)$ is not a zero of $f_n(t, u)$ for all $n \geq 1$, and the parameters satisfy one of the following cases:

1. $a = B(1 - d - B), b = -eB, c = 0, C = E = 0$.
(2) $B = C = 0, d = e = E = 1$;
(3) $e = B = C = 0, E = 1$;
(4) $d = -1, e = 0, B = 2, C = 0, E = -1$;
(5) $a = B(1 - d - B), b = 1 - d - 2B - eB, c = -1 - e, C = 1, E = 0$;
(6) $d = E = -1, e = 0, B = 2, C = 1$.

Conversely, if $(a, d)$ is not a zero of $f_n(t, u)$ for all $n \geq 1$, and the parameters satisfy the conditions in one of (1)–(6), then $T$ is a twisted tensor product of $R$ and $S$.

Moreover, all of the algebras described in (1)–(6) are Koszul.

Proof. Since $G_2 = 0$, $A = 0$ and, from the Jordan normal form, we can assume $C \in \{0, 1\}$. If $C = 0$, then the equation (4) in Lemma 4.9 implies $E \in \{0, 1\}$ or $e = 0$. Case (1) results from setting $C = E = 0$ in the equations of Lemma 4.9. If $C = 0$ and $E \neq 0$ then the third equation of Lemma 4.9 implies $B + E = 1$ hence the last equation becomes $eB = 0$. Recall that in Jordan normal form $e \in \{0, 1\}$. If $e = 1$ then $B = 0$ and $d = E = 1$; this is case (2). If $e = 0$, then from the fourth equation of Lemma 4.9 we see that $B(1 + d) = 0$ so $B = 0$ or $d = -1$. These are cases (3) and (4), respectively.

If $C = 1$ then $E = 0$ or $B + E = 1$. If $E = 0$, we have case (5). If $E \neq 0$, then $B + E = 1$ and, from the last equation of Lemma 4.9 $1 + E + eB = 0$. These two equations imply $B \neq 0$ so $d = -1$. Since $a \neq 1$, the first equation implies $E = -1$ and hence $B = 2$. This is case (6).

\[\square\]

4.3. The elliptic case, $f = 1$ and $G_2 \neq 0$.

Lemma 4.11. If $T$ is a graded twisted tensor product in Jordan normal form such that $G_2 \neq 0$, then $A = 1, d = E = -1, e = 0$, and $b = (1 - a)(2 - B)$.

Proof. By Lemma 4.10, we have $A = 1, d = -1$ and $G_1 = (1 - a)G_2$. Recall that either, $e = 0$ or $e = 1$ and $d = E$. Suppose the latter holds. Comparing the coefficients of $x^2z$ in $G_1$ and $G_2$, we see that $a - 2 = a - 1$, a contradiction. Thus $e = 0$. Now $G_1$ and $G_2$ simplify to:

\[
G_1 = (a - 1)zx^2 - (a - 1)x^2z + bx^3 + bEyzz - byxz + (bB + c + CE)yx^3 + (cE^2 - c)y^2z + (bC + cB + cBE)y^2x + (cC + cCE)y^3
\]

\[
G_2 = -zx^2 - Ex^2z + (2 - B)x^3 + (E - BE - E^2)yzx - (-E + BE + E^2)yz + (2B - a - B^2 - C - CE + aE)x^2 + (CE^2 + CE)y^2z + (2C - b - 2BC - BCE + bE^2)y^2x - (c + C^2 + C^2E - cE^2)y^3.
\]

Since $G_1 = (1 - a)G_2$, it follows that $E = -1$ and $b = (1 - a)(2 - B)$.

We note that the conditions $A = 1, d = E = -1, e = 0$ and $b = (1 - a)(2 - B)$ imply $G_1 = (1 - a)G_2$, so there are no additional restrictions on the parameters to consider.

Now we will prove that the conditions of Lemma 4.11 ensure that $T$ is a graded twisted tensor product.
Proposition 4.12. Let $T = T(a, (1 - a)(2 - B), c, -1, 0, 1; 1, B, C, 0, -1, 0)$, so $b = (1 - a)(2 - B)$. The algebra $T$ has a finite Gröbner basis:

$z^2 = zx - ax^2 - byx - cy^2 + xz$
$zy = x^2 + Byx + Cy^2 - yz$
$xy = yx$
$zx^2 = x^2 z - \beta yxz + \beta x^3 + B\beta yx^2 + C\beta y^2 x - \beta yxz$.

In particular, $\{y^j x^i (xz)^k z^l : i, j, k \geq 0, l \in \{0, 1\}\}$ is a linear basis for $T$, and the Hilbert series of $T$ is $1/(1-t)^3$.

Proof. Since the conditions $A = 1, d = E = -1, e = 0$ and $b = (1 - a)(2 - B)$ imply $G_1 = (1 - a)G_2$, adding $w = zx^2 - (x^2 z - \beta yxz + \beta x^3 + B\beta yx^2 + C\beta y^2 x - \beta yxz)$ to the set $\mathcal{S}$ makes both overlaps $z^3$ and $z^2 y$ reducible. Two new overlaps are created: $z^2 x^2$ and $z^2 y$. These overlaps both resolve as well. Thus $\mathcal{S} \cup \{w\}$ determines a finite Gröbner basis for $T$.

The stated basis is precisely the set of monomials that do not contain any of $xy, zy, z^2$, or $zx^2$ as subwords. The Hilbert series follows by an easy counting argument.

Proposition 4.13. The set $S = \{y^j x^i z^k : i, j, k \geq 0\}$ is a $k$-basis for $T$.

Proof. Let $U$ denote the $k$-linear span of $S$. To show that $U = T$, it suffices to prove that for all $k \geq 0$, that $(zx)^k$ and $(zx)^k z$ are in $U$.

To start we recall that $zy = x^2 + Byx + Cy^2 - yz$, and note that it is easy to show that $z^2 y = x^2 z + \beta x^3 + (B - a)\beta yx^2 + (C - b)\beta y^2 x - c\beta y^3 - \beta yz^2$.

Next we claim that $z^2 x^j$ and $zx^j$ are in $U$. One checks that $z^2 x = f(x, y) + (x - \beta y)z^2$, where $f(x, y) = \beta x^3 + (B\beta - a)yx^2 + (C\beta - b)y^2 x - \beta cy^3$. Now for $j > 1$,
$z^2 x^j = (f(x, y) + (x - \beta y)z^2)x^j - 1$,
so inductively we see that $z^2 x^j \in U$. Furthermore, $zx = ax^2 + byx + cy^2 + z^2 - xz \in U$ and hence $zx^j = ax^2 + byx + cy^2 + z^2 - xz)x^j - 1$,
so inductively $zx^j \in U$.

Now we claim that $(zx)^i z$ and $(zx)^i$ are in $U$. Suppose, inductively, that $(zx)^i \in U$. Then obviously $(zx)^i z \in U$. Write $(zx)^i = \sum a_{jkl} y^j x^k z^l$. Then $(zx)^{i+1} = (zx)(zx)^i = (ax^2 + byx + cy^2 + z^2 - xz) \sum a_{jkl} y^j x^k z^l$,
and it is apparent from the observations above that $(zx)^{i+1} \in U$.

The fact that the Hilbert series of $T$ is $1/(1-t)^3$ implies that $S$ is linearly independent.

Theorem 4.14. The algebra $T = T(a, (1 - a)(2 - B), c, -1, 0, 1; 1, B, C, 0, -1, 0)$ is a twisted tensor product of $R$ and $S$. Moreover, the generators $x, y, z$ of $T$ are left and right regular.
Proof. The first statement follows from Proposition 4.13 and the Hilbert series of $T$. For the second statement, note that $T \cong T^{op}$, as graded algebras. It follows that an element of $T$ is left regular if and only if it is right regular. It is clear from the basis $\{y^i x^j z^k : i, j, k \geq 0\}$, and the fact that $x$ and $y$ commute, that $x$ and $y$ are right regular and that $z$ is left regular.

□

We conclude this section by remarking that, up to isomorphism, all of the quadratic twisted tensor products of $R$ and $S$ are described in Theorem 4.3 (Ore type), Theorem 4.10 (reducible type), Theorem 4.14 (elliptic type).

5. The Koszul property and Yoneda algebras

We continue to use the notation $R = \mathbb{K}[x, y]$, $S = \mathbb{K}[z]$ and $T = T(a, b, c, d, e, f; A, B, C, D, E, F)$. In this section we determine which of the quadratic twisted tensor products of $R$ and $S$ are Koszul. In [6] it was asked if there exist Koszul algebras: $R$ and $S$, and a twisting map $\tau : S \otimes R \to R \otimes S$ such that the algebra $R \otimes_{\tau} S$ is quadratic, but not Koszul. Theorem 5.6 below affords examples of this phenomenon. We also compute the structure of the Yoneda algebra for these non-Koszul examples. (Recall that for a Koszul algebra, the Yoneda algebra and the quadratic dual algebra are isomorphic; see [8, Definition 1, p. 19] for example.)

5.1. The Koszul property. In the case of an Ore-type or reducible twisted tensor product, the Koszul property follows immediately from the results in the preceding section.

Theorem 5.1. Let $T$ be a quadratic twisted tensor product of $R$ and $S$. If $T$ is Ore type or reducible type, then $T$ is Koszul.

Proof. If $T$ is Ore type, then $T$ is a graded Ore extension of $R$ by Proposition 4.2. Since $R$ is Koszul, it is well-known that $T$ is Koszul; see [8, Chapter 4, Section 7, Example 2], for example.

If $T$ is reducible type, then $T$ is Koszul by Theorem 4.8.

□

It remains to consider the quadratic twisted tensor products where $A = 1$. Recall that these are described in Theorem 4.14. It is convenient, for this section and the remainder of the paper, to change the presentation of the algebras of this type. This change of presentation, albeit motivated by easing computations, is also natural in a certain sense: the cubic equation defining the point scheme (generically an elliptic curve) is in Weierstrass form (see, for example, [11, Chapter III.1]). In order to make this change of presentation it is necessary to assume that $\text{char} \mathbb{K} \neq 2$. We note that our main results, Theorem 5.6 and Theorem 6.2(3) below, can be proved by the exact same methods without changing presentation, hence they can be seen to hold over any field.

Lemma 5.2. Suppose that $\text{char} \mathbb{K} \neq 2$. Define

$$\beta = 2 - B, \quad \gamma = C + 2(a - 1), \quad g = \gamma + \beta^2/4, \quad h = c - (a - 1)(C + a - 1).$$

The algebra $T(a, (1 - a)(2 - B), c, -1, 0, 0, 1, B, C, 0, -1, 0)$ can be presented as

$$\mathbb{K}\langle x, y, w \rangle / (wy + yw - x^2 - gy^2, w^2 + hy^2, xy - yx).$$
Proof. This is a straightforward computation using the invertible change of variables: 

\[ x \mapsto x + (\beta/2)y, \quad y \mapsto y, \quad z \mapsto w + x - (a - 1)y. \]

\[ \square \]

Using this lemma, we change notation and write

\[ T(g, h) = T(a, (1 - a)(2 - B), c, -1, 0, 0; 1, B, C, 0, -1, 0). \]

When we use this notation, implicitly we are assuming that \( \text{char } K \neq 2 \). Below we will establish when the Koszul property holds for \( T(g, h) \) by computing a minimal \( \text{graded free resolution of the trivial module } T/tK. \) That calculation makes use of the Gröbner basis described in the next lemma.

Lemma 5.3. Order the generators of \( T(g, h) \) as \( y < x < w \) and use left lexicographical on monomials in \( K[y, x, w] \). Then \( T(g, h) \) has a finite Gröbner basis:

\[
\begin{align*}
xy - yx \\
w^2 - x^2 - gy^2 \\
w^2 + hy^2 \\
w^2 - x^2 w.
\end{align*}
\]

Consequently, \( \{ y^i x^j (wx)^k w^l : i, j, k \geq 0, l \in \{0, 1\} \} \) is a K-basis for \( T(g, h) \). The elements \( x^2 \) and \( y^2 \) are central in \( T(g, h) \).

Proof. The proof of the first statement is a straightforward computation using Bergman’s diamond lemma. The second and third statements follow immediately from the Gröbner basis. \( \square \)

For later reference, we fix the following sequences of graded free modules, which we will prove are resolutions of \( T/T_+ = tK \).

Definition 5.4. Let \( T = T(g, h) \).

(1) If \( h \neq 0 \), define \( (Q_\bullet, d_{Q_\bullet}^2) \) to be the sequence

\[
0 \rightarrow T(-3) \xrightarrow{d_{Q_3}^2} T(-2) \xrightarrow{d_{Q_2}^2} T(-1) \xrightarrow{d_{Q_1}^2} T,
\]

where

\[
d_{Q_3}^2 = [hy \quad w \quad -hx], \quad d_{Q_2}^2 = \begin{bmatrix}
-x & w - gy & y \\
0 & hy & w \\
-y & x & 0
\end{bmatrix}, \quad d_{Q_1}^2 = \begin{bmatrix}
x \\
y \\
w
\end{bmatrix}.
\]

(2) If \( h = 0 \), define for each \( i \geq 0 \) a graded free left \( T \)-module by

\[
P_i = \begin{cases}
T & i = 0 \\
T(-1)^3 & i = 1 \\
T(-2)^3 & i = 2 \\
T(-i) \oplus T(-i - 1) & i \geq 3.
\end{cases}
\]

Also, define a map \( d_{P_i}^P : P_i \rightarrow P_{i-1} \) via

\[
\begin{align*}
d_{P_1}^1 &= \begin{bmatrix}
x \\
y \\
w
\end{bmatrix},
& d_{P_2}^1 &= \begin{bmatrix}
-x & w - gy & y \\
0 & 0 & w \\
-y & x & 0
\end{bmatrix},
& d_{P_3}^1 &= \begin{bmatrix}
0 & w & 0 \\
wy & -y^2 & -wx
\end{bmatrix},
& d_{P_4}^1 &= \begin{bmatrix}
w & 0 \\
y^2 & w
\end{bmatrix},
\end{align*}
\]
and for all \( i \geq 5 \),
\[
d_i^P = \begin{bmatrix} w & 0 \\ y^2 & -w \end{bmatrix}.
\]

Using Lemma 5.3, it is easy to check that \((Q_\bullet, d^Q_\bullet)\) and \((P_\bullet, d^P_\bullet)\) are complexes of graded free modules with coker \( d^Q_i \) and coker \( d^P_i \) isomorphic to \( T/T_+ = T\mathcal{K} \).

The following standard fact is very useful for proving exactness of complexes of locally finite graded modules.

**Lemma 5.5.** Let \( C_\bullet : 0 \to V_n \to V_{n-1} \to \cdots \to V_1 \to V_0 \to 0 \) be a finite complex where the \( V_i \) are finite-dimensional vector spaces. Then
\[
\sum_{i=0}^{n} (-1)^i \dim(V_i) = \sum_{i=0}^{n} (-1)^i \dim(H_i(C_\bullet)).
\]

Now we are ready to use Lemma 5.3 to prove the main theorem of this section.

**Theorem 5.6.** Let \( T = T(g, h) \). The complexes \((Q_\bullet, d^Q_\bullet)\) and \((P_\bullet, d^P_\bullet)\) are graded free \( T \)-module resolutions of \( T\mathcal{K} \) when \( h \neq 0 \) and \( h = 0 \), respectively. In particular, the algebra \( T(g, h) \) is Koszul if and only if \( h = c - (a-1)(C_a + a-1) \) is nonzero.

**Proof.** Let \( T = T(g, h) \). Since each \( Q_i \) is generated in degree \( i \), but \( P_i \) is generated in degrees \( i \) and \( i+1 \) for \( i \geq 3 \), it suffices to prove that \((Q_\bullet, d^Q_\bullet)\) and \((P_\bullet, d^P_\bullet)\) are exact in homological degrees greater than \( 0 \).

Assume that \( h \neq 0 \). We claim that the map \( d_3^Q \) is injective. Suppose that \( t \in \ker(d_3^Q) \). Then \( tx = ty = tw = 0 \). Notice that we recover the original presentation of the algebra \( T \) if we set \( z = w + x - (a-1)y \). Thus \( t \) left annihilates the generators \( x, y, z \) of \( T \). Then Theorem 4.14 implies that \( t = 0 \), as desired. We have shown that the complex
\[
0 \to T(-3) \xrightarrow{d_2^Q} T(-2)^3 \xrightarrow{d_2^Q} T(-1)^3 \xrightarrow{d_3^Q} T
\]
is exact at \( T(-3) \); since \( T \) is quadratic, the complex is exact at \( T(-1)^3 \). Because the Hilbert series of \( T \) is \((1-t)^{-3} \), it follows that the complex is exact. Since \( T \) has a linear free resolution, we conclude that \( T \) is Koszul when \( h \neq 0 \).

Now assume that \( h = 0 \). Notice that \( w^2 = 0 \) in \( T \) so the \( \mathbb{K} \)-basis described in Lemma 5.3 is \( [0 \ 0 \ 0] \) is not injective. Since \( T \) is quadratic, the complex \((P_\bullet, d^P_\bullet)\) is exact at \( T(-1)^3 \).

Now we prove exactness at \( T(-3) \). Suppose that \([u_1 \ u_2] \in \ker(d_3^P) \). Then it follows that \( u_2 wy = 0 \). From the \( \mathbb{K} \)-basis described in Lemma 5.3 we see that \( u_2 = rw \) for some \( r \in T \). We also have \( u_1w - u_2y^2 = 0 \), so, using the fact that \( y^2 \) is central, we have \((u_1 - ry^2)w = 0 \). The left annihilator ideal of \( w \) is \( Tw \), so \( u_1 - ry^2 = uw \) for some \( u \in T \). Therefore
\[
[u_1 \ u_2] = [wy^2 + uw \ rw] = w[0 \ 0] + ry^2 \in \im(d_4^P).
\]
We conclude exactness at \( T(-3) \).

A similar, and easier, argument is used to show exactness in homological degree \( i \) for all \( i \geq 4 \). We leave this argument to the reader.

To show exactness at \( T(-2)^3 \), note that for any fixed homogeneous degree \( j \), the complex \((P_\bullet, d^P_\bullet)\) restricts to a finite complex of finite-dimensional vector spaces. Let \( q(t) \) denote the Hilbert series of the homology group \( H_2(P_\bullet) \), and let \( H_T \) denote
the Hilbert series of $T$. Then the Hilbert series of $T(-i)$ is $t^i H_T$. Appending $T \to \tau T \to 0$ to $(P_\bullet, d_\bullet)$ and applying Lemma 5.5 yields
\[1 - H_T + 3t H_T - 3t^2 H_T + t^3 H_T = -q(t).\]
Rearranging and using the fact that $H_T = (1 - t)^{-3}$ we have
\[1 + q(t) = H_T(1 - 3t + 3t^2 - t^3) = 1,
so $q(t) = 0$. We conclude exactness of $P_\bullet$ at $T(-2)^3$. Thus, $(P_\bullet, d_\bullet)$ is a graded free resolution of $T \cdot K$.

\[\square\]

5.2. The Yoneda algebra of $T(g,h)$. For any graded algebra $A$, the graded Hom functor for graded left $A$-modules is
\[\text{Hom}_A(M, N) = \bigoplus_{n \in \mathbb{Z}} \text{Hom}_A^0(M, N) = \bigoplus_{n \in \mathbb{Z}} \hom_A(M, N[n]),\]
where $\hom_A(M, N[n])$ is the space of degree 0 graded $A$-module homomorphisms $M \to N[n]$. This functor is left exact, and its $i$-th right derived functor is denoted $\text{Ext}_A^i(M, N)$. The space $\text{Ext}_A^i(M, N)$ inherits a grading from the graded Hom functor, and we denote the homogeneous degree $j$ component by $\text{Ext}_A^{i,j}(M, N)$.

One may compute the space $\text{Ext}_A^i(M, N)$ as the homology group $H^i(P_\bullet, N)$ where $(P_\bullet, d_\bullet)$ is a graded free resolution of $M$. Thus
\[\text{Ext}_A(M, N) = \bigoplus_i \text{Ext}_A^i(M, N) = \bigoplus_{i,j} \text{Ext}_A^{i,j}(M, N)\]
is bigraded. When $M = N = A \mathbb{K}$, we abbreviate $E^{i,j}(A) = \text{Ext}_A^{i,j}(A, A)$, $E^i(A) = \bigoplus_j E^{i,j}(A)$ and $E(A) = \bigoplus_i E^i(A)$. The vector space $E(A) = \text{Ext}_A(A, A)$ admits the structure of a bigraded algebra called the Yoneda algebra via the Yoneda composition product. We briefly recall the definition of this product, see [8, p. 4] for more details.

Let $\alpha \in E^i(A)$ and $\beta \in E^j(A)$. The product $\alpha \ast \beta \in E^{i+j}(A)$ is defined as follows. Choose representatives $f \in \text{Hom}_A(P_i, A)$ and $g \in \text{Hom}_A(P_j, A)$ for the classes $\alpha$ and $\beta$, respectively. Using projectivity, one lifts $g$ as in the first two rows of the following diagram to obtain a map $g_i \in \text{Hom}_A(P_{i+j}, P_i)$. Then $\alpha \ast \beta$ is defined to be $[f \circ g_i] \in E(A)^{i+j}$.

\[
\begin{array}{cccccc}
P_{i+j} & \longrightarrow & P_{i+j-1} & \longrightarrow & \cdots & \longrightarrow & P_j \\
\downarrow g_i & & \downarrow g_{i-1} & & & \downarrow g_l \downarrow g \\
P_i & \longrightarrow & P_{i-1} & \longrightarrow & \cdots & \longrightarrow & P_0 \\
\downarrow f & & & & & \downarrow e \downarrow \epsilon \\
\mathbb{K} & & & & \mathbb{K} & & \mathbb{K}
\end{array}
\]

We conclude this section by establishing a presentation for the Yoneda algebra of $T(g,h)$. This family of examples illustrates that, in general, relationships between the Yoneda algebras of $R$, $S$ and $R \otimes \tau S$ may not be simple or obvious.

Let $T = T(g,h)$. Let $(Q_\bullet, d_\bullet^Q)$ and $(P_\bullet, d_\bullet^P)$ be the complexes of graded free $T$-modules constructed in Definition 5.4. Recall that by Theorem 5.6 these are graded free resolutions of $T \cdot K$ when $h \neq 0$ and $h = 0$, respectively. Since $im d_\bullet^Q \subset T\cdot Q_{i-1}$ and $im d_\bullet^P \subset T\cdot P_{i-1}$, these resolutions are minimal: all differentials in
the complexes $\text{Hom}_T(Q, \mathbb{K})$ and $\text{Hom}_T(P, \mathbb{K})$ are trivial. Thus by Theorem 5.6 we may take $E^i(T) = \text{Hom}_T(Q_i, \mathbb{K})$ and $E^i(T) = \text{Hom}_T(P_i, \mathbb{K})$ as our models of $\text{Ext}^i_T(\mathbb{K}, \mathbb{K})$, according to whether or not $h = 0$.

Let $\chi, \nu, \omega \in E^{1,1}(T)$ denote dual basis vectors to $x, y, w \in T_1$, respectively. In the case $h = 0$, let $\rho \in E^{3,4}(T)$ denote the graded $T$-linear map: $\rho : T(-3) \oplus T(-4) \rightarrow \mathbb{K}$ given by $\rho(1,0) = 0$, $\rho(0,1) = 1$.

**Theorem 5.7.** Retain the notation of the previous paragraph. Then the Yoneda algebra $E(T)$ of $T(g,h)$ can be presented as follows.

1. If $h \neq 0$, then $E(T)$ is generated by $\chi, \nu, \omega$ subject to the quadratic relations:
   \[
   \chi \nu + \nu \chi, \chi \omega, \omega \nu - \nu \omega, \nu \omega + \chi^2, \nu^2 - h\omega^2 - g\chi^2.
   \]

2. If $h = 0$, then $E(T)$ is generated by $\chi, \nu, \omega, \rho$ subject to the quadratic relations:
   \[
   \chi \nu + \nu \chi, \chi \omega, \omega \nu - \nu \omega, \nu \omega + \chi^2, \nu^2 - g\chi^2,
   \]
   **quartic relations:**
   \[
   \chi \rho, \nu \rho, \rho \chi, \rho \nu, \omega \rho + \rho \omega,
   \]
   and one sextic relation: $\rho^2$.
   Moreover, for all $i \geq 3$, $E^{i,i}(T) = \mathbb{K}\omega^i$ and $E^{i,i+1}(T) = \mathbb{K}\omega^{i-3}\rho$.

**Proof.** By Theorem 5.6 $T$ is Koszul if $h \neq 0$. In this case it is well-known, for example see [8, Chapter 2, Definition 1 (c)], that $E(T)$ is isomorphic to the quadratic dual algebra, $T^!$. This algebra is generated by the space $T_1^!$, and its defining (quadratic) relations are those elements of $(T_1^!)^{\ast} \otimes (T_1^!)^{\ast}$ orthogonal to all quadratic relations of $T$ under the natural pairing. Thus statement (1) follows by checking orthogonality of the stated relations with those of $T$, and a simple dimension count.

Now we prove (2). Assume that $h = 0$, and set $T = T(g,0)$. It follows from [8, Proposition 3.1, p. 7] that the diagonal subalgebra, $\oplus E^{i,i}(T) \subset E(T)$ is isomorphic to the quadratic dual algebra, $T^!$. The quadratic relations of $T^!$, in this case, are obtained from the quadratic relations in (1) by setting $h = 0$.

In order to prove that the quartic expressions given in (2) are in fact relations of $E(T)$, we use the model $E^i(T) = \text{Hom}_T(P_i, \mathbb{K})$ for $\text{Ext}^i_T(\mathbb{K}, \mathbb{K})$, where $(P_*, d^*_T)$ is the graded free resolution of $T \mathbb{K}$ constructed in Definition 5.4. The differentials are written in terms of matrices with respect to the natural canonical bases for the free modules appearing in the resolution. Let $\xi \in E^{4,5}(T)$ denote the graded $T$-linear map: $\xi : T(-4) \oplus T(-5) \rightarrow \mathbb{K}$ given by $\xi(1,0) = 0$, $\xi(0,1) = 1$. With respect to these bases, we have

\[
\chi = \begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix}, \quad \nu = \begin{bmatrix} 0 \\ 1 \\ 0 \end{bmatrix}, \quad \omega = \begin{bmatrix} 0 \\ 0 \\ 1 \end{bmatrix}, \quad \rho = \begin{bmatrix} 0 \\ 0 \\ 1 \end{bmatrix}, \quad \xi = \begin{bmatrix} 0 \\ 1 \\ 1 \end{bmatrix}.
\]

Now we check that $\rho \omega + \omega \rho = 0$ in $E(T)$. We will show that $\omega \rho = \xi$ and $\rho \omega = -\xi$.

In order to compute $\omega \rho$, we must lift $\rho$ as in the first two rows of the following diagram.
Let
\[ \rho_0 = \begin{bmatrix} 0 \\ 1 \end{bmatrix}, \quad \rho_1 = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 1 \end{bmatrix}, \quad \rho_2 = \begin{bmatrix} 0 & 0 & 0 \\ 0 & -1 & 0 \end{bmatrix}, \]
and
\[ \rho_i = \begin{bmatrix} 0 \\ (-1)^{i+1} \end{bmatrix}, \quad \text{for all } i \geq 3. \]
Then it is straightforward to check that these maps do indeed complete the above diagram. The map \( \omega \circ \rho_1 \) is given by the matrix \( \begin{bmatrix} 0 & 1 \end{bmatrix} \), so we conclude that \( \omega \rho = \xi \).

Now we compute \( \rho \omega \). We must lift \( \omega \) through the first two rows of the following diagram.

Let
\[ \omega_0 = \begin{bmatrix} 0 \\ 0 \end{bmatrix}, \quad \omega_1 = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 0 & 0 & 0 \end{bmatrix}, \quad \omega_2 = \begin{bmatrix} 0 & 1 & 0 \\ -y & 0 & 0 \\ x & 0 & -1 \end{bmatrix}, \quad \omega_3 = \begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix}, \]
and
\[ \omega_i = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}, \quad \text{for all } i \geq 4. \]
One checks that these maps complete the last diagram. The map \( \rho \circ \omega_3 \) is given by the matrix \( \begin{bmatrix} 0 & -1 \end{bmatrix} \), so we conclude that \( \rho \omega = -\xi \). It follows that \( \rho \omega + \omega \rho = 0 \) in \( E(T) \), as claimed. The other quartic relations can be proved via similar computations.

Note that because the Yoneda algebra is bigraded, \( \rho^2 \in E^{6,8}(T) \). The minimal resolution \( (P_*, d^P_*) \) constructed in Definition 5.4 has \( P_6 = T(-6) \oplus T(-7) \), so \( E^{6,8}(T) = 0 \). Hence \( \rho^2 = 0 \) in \( E(T) \).

Now we prove the last statement of (2). Using the definitions of the maps \( \rho_i, \omega_i \) given above, it is easy to compute that for all \( i \geq 3 \), \( \omega^i \in E^{i,i}(T) \) is given by the matrix \( \begin{bmatrix} 1 & 0 \end{bmatrix} \); and for all \( j \geq 1 \), \( \omega^j \rho \in E^{j+3,j+4}(T) \) is given by the matrix \( \begin{bmatrix} 0 & (-1)^{j+1} \end{bmatrix} \). Therefore, since we know by Definition 5.4 (2) that \( E^{i,i}(T) \) and \( E^{j+3,j+4}(T) \) are both 1-dimensional, we have \( E^{i,i}(T) = \mathbb{K} \omega^i \) for all \( i \geq 3 \) and \( E^{j+3,j+4}(T) = \mathbb{K} \omega^j \rho \) for all \( j \geq 0 \).
Using the minimal resolution \((P_*, dP_*)\), we know the Hilbert series of \(E(T)\). Then

a straightforward Gröbner basis argument shows that the algebra with generators \(\chi, \nu, \omega, \rho\) and defining relations as in (2) has the same Hilbert series as \(E(T)\). Hence, the relations given in (2) are in fact a complete set of defining relations for \(E(T)\).

When \(T(g, h)\) is Koszul, it is natural to ask if \(E(T)\) is isomorphic to a twisted tensor product of the Yoneda algebras \(E(R)\) and \(E(S)\), since at least as graded vector spaces: \(E(T) = E(R) \otimes E(S)\).

**Proposition 5.8.** If \(T(g, h)\) is Koszul, then \(E(T(g, h))\) is not isomorphic to a twisted tensor product of \(E(R)\) and \(E(S)\).

**Proof.** Let \(T = T(g, h)\) and assume \(T\) is Koszul. Suppose, to the contrary, that \(E(T)\) is isomorphic to a twisted tensor product of \(E(R)\) and \(E(S)\). By the standard fact that the polynomial ring \(R\) is a quadratic Koszul algebra, \(E(R)\) is isomorphic to the exterior algebra \(\Lambda(x, y) = \mathbb{K}(x, y)/\langle x^2, y^2, xy + yx \rangle\). It follows that \(E(T)\) has a subalgebra isomorphic to \(\Lambda(x, y)\).

Therefore there exist linearly independent elements \(\alpha, \beta \in E^1(T)\), such that \(\alpha^2 = \beta^2 = \alpha\beta + \beta\alpha = 0\). However, now we rule out the existence of such elements.

We use the presentation for \(E(T)\) given in Theorem 5.7 (1). Order the generators by \(\omega < \chi < \nu\), and order monomials in the free algebra \(\mathbb{K}(\chi, \nu, \omega)\) by degree and left-lexicographic order. Then the associated Gröbner basis in degree 2 is:

\[
\nu \chi + x \nu, \chi \omega, \omega \chi, \nu \omega - \omega \nu, \chi^2 + \omega \nu, \nu^2 - g \chi^2 - h \omega^2.
\]

Consider an element \(\gamma = a\chi + b\omega \neq 0\), where \(a, b \in \mathbb{K}\). Then, in terms of the monomial basis determined by the Gröbner basis,

\[
\gamma^2 = -a^2 \omega \nu + b^2 \omega^2,
\]

so \(\gamma^2 \neq 0\).

Write \(\alpha = a_\omega \omega + a_\chi \chi + a_\nu \nu\) and \(\beta = b_\omega \omega + b_\chi \chi + b_\nu \nu\) for some \(a_\omega, a_\chi, a_\nu, b_\omega, b_\chi, b_\nu \in \mathbb{K}\). It follows from the last paragraph, that \(a_\nu\), and \(b_\nu\) are both nonzero. Without loss of generality, by multiplying \(\alpha\) and \(\beta\) by appropriate scalars, we may assume that \(a_\nu = b_\nu = 1\). Since \(\alpha\) and \(\beta\) are linearly independent, \(\alpha - \beta \neq 0\), and the \(\nu\) component of \(\alpha - \beta\) is zero. Thus, \((\alpha - \beta)^2 \neq 0\). However, computing directly and using our assumptions,

\[
(\alpha - \beta)^2 = \alpha^2 - \alpha\beta - \beta\alpha - \beta^2 = 0,
\]

a contradiction.

Hence, \(E(T)\) is not isomorphic to a twisted tensor product of \(E(R)\) and \(E(S)\). \(\square\)

**Remark 5.9.** It is also natural to ask if the algebra \(T(g, 0)\) becomes Koszul after regrading: \(\deg(\rho) = 1\). However, this is not the case. For example, if \(g \in \{0, 1\}\), then, after regrading, \(T(g, 0)\) is not Koszul. Nevertheless, further study of \(E(T)\) seems interesting when \(h = 0\).

6. Artin-Schelter regularity

We continue to use the notation \(R = \mathbb{K}[x, y]\) and \(S = \mathbb{K}[z]\). In this section we determine when a quadratic twisted tensor product of \(R\) and \(S\) is Artin-Schelter regular. This notion was introduced by Artin and Schelter in [4].
**Definition 6.1.** A graded algebra, $A$, is called **AS-regular** of dimension $d$ if (i) $\text{gldim}(A) = d < \infty$; (ii) $\text{GKdim}(A) < \infty$; and (iii) $A$ is **Gorenstein**: $\text{Ext}^n_A(\mathbb{K}, A) = 0$ if $n \neq d$, and $\text{Ext}^d_A(\mathbb{K}, A) \cong \mathbb{K}$.

Recall that every quartic twisted tensor product of $R$ and $S$ is isomorphic as a twisted tensor product of $R$ and $S$ to one of the algebras described in Theorem 4.3 (Ore type), Theorem 4.10 (reducible type), and Theorem 4.14 (elliptic type). The property of AS-regularity is an algebra-isomorphism invariant, so the following result completely determines when a quadratic twisted tensor product of $R$ and $S$ is AS-regular.

**Theorem 6.2.** Let $T$ denote a quadratic twisted tensor product of $R$ and $S$.

1. If $T$ is an algebra of Ore type, then $T$ is AS-regular if and only if $T \cong R[z; \sigma, \delta]$ where $\sigma \in \text{End}(R)$ is invertible.
2. If $T$ is an algebra of reducible type, then $T$ is AS-regular if and only if $E \neq 0$ and $a + d \neq 0$.
3. Assume that $\text{char} \mathbb{K} \neq 2$. If $T$ is an algebra of elliptic type, then $T$ is AS-regular if and only if $h = c - (a - 1)(C + a - 1) \neq 0$.

**Proof.** Let us begin by showing that an algebra in the context of (1) or (2) has global dimension equal to 3. If $T$ is an algebra of Ore type or reducible type, then $T$ is Koszul by Theorem 5.1. Then the fact that the Hilbert series of $T$ is $(1 - t)^{-3}$ implies that $\text{gldim}(T) = 3$.

Let $T$ denote an algebra of Ore type. By Proposition 4.2, $T$ is an Ore extension of the form $R[z; \sigma, \delta]$. If $\sigma$ is not invertible, then $T$ is not a domain. It is known that every global dimension 3 AS-regular algebra is a domain, see [1] Theorem 8.1 and [2] Theorem 3.9, so if $\sigma$ is not invertible, then $T$ is not AS-regular. Conversely, by [3] Proposition 2, if $\sigma$ is invertible, then $T$ is AS-regular.

Now we prove (2). Let $T$ be an algebra of reducible type. First we show that the conditions $E \neq 0$ and $a + d \neq 0$ are necessary for $T$ to be AS regular. If $E = 0$, then the equation $(z - Bx - Cy)y = 0$ holds in $T$, showing that $T$ is not a domain. As noted above, all AS-regular of global dimension 3 are domains, so $T$ is not AS-regular when $E = 0$.

The element $y \in T$ is normal, and the quotient algebra $T/\langle y \rangle$ is isomorphic to $\mathbb{K}\langle x, z \rangle/\langle z^2 - xz + dxz + ax^2 \rangle$. Notice that if $a + d = 0$, we have $z^2 - xz + dxz + ax^2 = (z - ax)(z - x)$.

By Theorem 4.10, we have $a \neq 1$ since $a$ is not a zero of $f_1 = 1 - t$. Therefore the algebra $T/\langle y \rangle$ is isomorphic to $K\langle x, y \rangle/\langle xy \rangle$, which is not noetherian. Hence $T$ is not noetherian. As shown in [1] Theorem 8.1, all AS-regular algebras of global dimension 3 are noetherian. Consequently, if $a + d = 0$, then $T$ is not AS-regular.

Finally, we show that $a + d \neq 0$ is a sufficient condition for $T$ to be AS-regular. Suppose that $a + d \neq 0$. By Theorem 3.9, the quotient algebra $T/\langle y \rangle$ is noetherian. It follows, see for example [1] Lemma 8.2, that $T$ is noetherian. Then a result of Stephenson and Zhang, [12] Corollary 0.2, implies that $T$ is AS-regular.

For (3), we use the notation $T(g, h)$ introduced in Section 5 for the algebra $T$. It is well-known, see [10] Theorem 2.2 for example, that quadratic AS-regular algebras are Koszul, so by Theorem 5.6 if $h = 0$, then $T$ is not AS-regular. Now suppose that $h \neq 0$. Recall from Theorem 5.6 that

$$0 \to T(-3) \xrightarrow{d^2} T(-2) \xrightarrow{d^2} T(-1) \xrightarrow{d^2} T,$$
where
\[ d_Q^3 = \begin{bmatrix} hy & w & -hx \\ -x & w & gy \\ -y & x & 0 \end{bmatrix}, \quad d_Q^2 = \begin{bmatrix} x & w & gy \\ 0 & hy & w \\ y & 0 & 0 \end{bmatrix}, \quad d_Q^1 = \begin{bmatrix} x \\ y \\ w \end{bmatrix}, \]
is a minimal resolution of $\mathbb{T}_K$ by graded free $T$-modules. In particular, the global dimension of $T$ is 3.

Since the Hilbert series of $T$ is $(1 - t)^{-3}$, we know that the Gelfand-Kirillov dimension of $T$ is 3. Hence to show that $T$ is AS-regular, we only need to verify the Gorenstein condition; it is clear that this condition is equivalent to the exactness of the dual complex of graded right $T$-modules

\[ 0 \to T \xrightarrow{d_Q^3} T(1)^3 \xrightarrow{d_Q^2} T(2)^3 \xrightarrow{d_Q^1} T(3) \to \mathbb{K}_T(3) \to 0. \]

Since $h \neq 0$, this complex is exact at $T(3)$. It is straightforward to check that in the tensor algebra $T \langle x, y, w \rangle$, the entries of $d_Q^2 d_Q^3$ give a basis for the space of defining relations of $T$. Thus the complex is exact at $T(2)^3$. By Theorem 4.14 we know that $x$ is left regular, so the complex is exact at $T$. Finally, using Lemma 5.5 and the fact that the Hilbert series of $T$ is $(1 - t)^{-3}$ (as in the proof of Theorem 5.6) shows the complex is exact at $T(1)^3$.

\[ \square \]
