(Dated: May 21, 2013)

We point out that essentially all multi-band superconductors have an odd-frequency pairing component, as follows from a general symmetry analysis of even- and odd-frequency pairing states. We show that odd-frequency superconducting pairing requires only a finite band hybridization, or scattering, and non-identical intraband order parameters, of which only one band needs to be superconducting. Under these conditions odd-frequency odd-interband pairing is always present. From a symmetry analysis we establish a complete reciprocity between parity in band-index and frequency.

PACS numbers: 74.20.Rp, 74.45.+c, 74.78.Fk

One of the key aspects of superconductivity is the fermionic nature of the superconducting wave function, or equivalently the pair amplitude. This leads to the traditional classification into spin-singlet even-parity ($s$-, $d$-wave) or spin-triplet odd-parity ($p$-wave) pairing.

As Berezinskii\textsuperscript{1} originally showed, superconducting pairing can also be odd in time, or equivalently frequency. While theoretical proposals exist for odd-frequency bulk superconductors\textsuperscript{4,5}, odd-frequency pair amplitudes have so far only been argued to have been found in non-uniform systems\textsuperscript{4}. For example, at superconductor-ferromagnetic interfaces a conventional spin-singlet $s$-wave superconducting pair amplitude is transformed into an odd-frequency spin-triplet $s$-wave amplitude, due to spin-rotational symmetry breaking\textsuperscript{5,6}. The spin-triplet nature gives rise to long-range proximity effect into the ferromagnet. Also non-magnetic interfaces induce odd-frequency components, where instead translational symmetry breaking transforms a spin-singlet $s$-wave state into an odd-frequency spin-singlet $p$-wave state\textsuperscript{7,8}. The $p$-wave nature, however, makes this odd-frequency component sensitive to disorder\textsuperscript{9}.

Numerous recently discovered superconductors have multiple bands at the Fermi level. These include both the unconventional iron-pnictides/chalcogens\textsuperscript{10,11}, heavy fermion superconductors\textsuperscript{12,13}, and MgB\textsubscript{2}, a two-band phonon-driven superconductor\textsuperscript{15,16}. In these multi-band superconductors the band-index provides yet another symmetry index for the pair amplitude. While intraband pairing is, per definition, always an even function in band-index, both even- and odd-interband pairing are feasible.

In this Letter we show that odd-frequency pairing is ubiquitous in multi-band superconductors. By transforming between even- and odd-interband pairing, odd-frequency correlations are induced in the bulk of the superconductor, because the necessary symmetry breaking is, in general, present intrinsically in these systems. More specifically, we show that finite odd-frequency odd-interband pairing appears whenever there is a finite even-interband pairing between two non-identical bands. This is, for example, always the case when scattering, or hybridization, is present between two bands with non-identical intraband order parameters (of which one can be zero). Formally, we find that the orbital, or band, parity (O) of the pair amplitude in multi-band superconductors, together with spatial parity (P) and time reversal (T), needs to obey the rule $PTO = +1(-1)$ for spin-singlet (spin-triplet) pairing. There is thus a complete reciprocity between pairing that is odd in frequency and odd under band/orbital index permutation.

We start by establishing the formal possibility of odd-frequency pairing in multi-band superconductors. The previous classification for even/odd-frequency pairing has to be broaden when multiple bands are present, as it is now also dependent on the orbital (band) parity. We generalize the Berezinskii approach\textsuperscript{1} by considering an orbital (or band or species) dependent two fermion condensate $\Delta_{\alpha\beta,ab}(r,\tau) = T_r\langle c_{\alpha a}(r,\tau)c_{\beta b}(0,0)\rangle$. Here $\alpha, a$ refer to spin and orbital index, respectively. For concreteness we consider the case of two orbitals $a = 1, 2$. We define spatial parity (P) as acting on the relative coordinate $r$: $P\Delta_{\alpha\beta,ab}(r,\tau) = \Delta_{\alpha\beta,ab}(-r,\tau)$, time reversal (T) as acting on the relative time $\tau$: $T\Delta_{\alpha\beta,ab}(r,\tau) = \Delta_{\alpha\beta,ab}(r,-\tau)$, and orbital parity (O) as acting on the $a$ index: $O\Delta_{\alpha\beta,ab}(r,\tau) = \Delta_{\alpha\beta,ba}(r,\tau)$\textsuperscript{38}. The general symmetry requirement for a two fermion condensate can then be written as

$$PT\Delta_{\alpha\beta,ab}(r,\tau) = -\Delta_{\beta\alpha,ba}(r,\tau)$$

(1)

For spin-singlet $S = 0$ we further project to spin-singlet and find

$$\Delta_{ab}(-r, -\tau) = \Delta_{ba}(r, \tau)$$

(2)

which we shorthand as $PTO = 1$, namely, the simultaneous inversion of space, time, and permutation of orbital parity.
index will leave a spin-singlet pairing order parameter invariant. For the spin-triplet case (Δ now is a vector in spin space) a similar analysis leads to

$$\tilde{\Delta}_{ab}(-r,-\tau) = -\tilde{\Delta}_{ba}(r,\tau), \quad (3)$$

which we shorthand as \(PTO = -1\). The full symmetries of the two particle pair correlator are summarized in Table I.

![Table I: Behavior of the two fermion condensate under spatial parity (P), time-reversal (T), and orbital parity (O) symmetry for spin-singlet (S = 0, left), spin-triplet (S = 1, right) pairing, and different frequency (\(\omega\)) dependence.](image)

The results in Table I provide the formal evidence of odd-frequency pairing in multi-band superconductors by changing the orbital (band) parity. In order to show that odd-frequency pairing is also extremely common in multi-band superconductors we start with a generic two-band superconductor:

$$H_{ab} = \sum_{k,\sigma} \varepsilon_a(k) a_{k\sigma}^\dagger c_{k\sigma} + \varepsilon_b(k) b_{k\sigma}^\dagger b_{k\sigma} + \sum_{k,\sigma} \Gamma(k) a_{k\sigma}^\dagger b_{k\sigma} + H.c. + \sum_k \Delta_{a}(k) a_{k\uparrow}^\dagger a_{-k\downarrow} + \Delta_{b}(k) b_{k\uparrow}^\dagger b_{-k\downarrow} + H.c. \quad (4)$$

Here \(a_{k\sigma}^\dagger\) creates an electron in band \(a\) with momentum \(k\) and spin \(\sigma\), and similarly for band \(b\). The kinetic energy is given by the band dispersions \(\varepsilon_a, \varepsilon_b\) and a single-particle band scattering, or hybridization, \(\Gamma\). Finite \(\Gamma\) can appear if the superconducting pairing occurs in (atomic or molecular) orbitals in which the kinetic energy is not fully diagonal. It can also result from disorder-induced interband scattering [17]. The superconducting intraband (diagonal) order parameters are \(\Delta_{a,b}\). We will here assume conventional spin-singlet, uniform s-wave superconducting states, but the results apply equally well to any intraband pairing. For finite \(\Gamma\) we diagonalize the kinetic energy, resulting in a Hamiltonian with fully diagonal bands \(c\) and \(d\), but now with both intraband superconducting order parameters \(\Delta_{c}\) and \(\Delta_{d}\) and an even-interband order parameter \(\Delta_{cd}\):

$$H_{cd} = \sum_{k,\sigma} \varepsilon_c(k) c_{k\sigma}^\dagger c_{k\sigma} + \varepsilon_d(k) d_{k\sigma}^\dagger d_{k\sigma} + \sum_k \Delta_{c}(k) c_{k\uparrow}^\dagger d_{-k\downarrow} + \Delta_{d}(k) d_{k\uparrow}^\dagger c_{-k\downarrow} + H.c. + \sum_k \Delta_{cd}(k) (c_{k\uparrow}^\dagger d_{-k\downarrow} + d_{k\uparrow}^\dagger c_{-k\downarrow}) + H.c. \quad (5)$$

If we write \(\Delta_b = \alpha \Delta_a\), we can express \(\Delta_{cd} = (\alpha - 1) \Delta_a \Gamma / \sqrt{(\varepsilon_a - \varepsilon_b)^2 + 4|\Gamma|^2}\). Thus, even-interband pairing is always present whenever \(\Gamma \neq 0\) and \(\Delta_a \neq 0\) in the original Hamiltonian \(H_{ab}\).

We are here primarily interested in the s-wave time-ordered pairing amplitude:

$$F^\pm(\tau) = \frac{1}{2N_k} \sum_k (c_{-k\uparrow}(\tau) d_{k\uparrow}(0) \pm d_{-k\uparrow}(\tau) c_{k\uparrow}(0)), \quad (6)$$

which is an even (+) or odd (−) function in band index. \(N_k\) is the number of points in the Brillouin zone. \(F^\pm(\tau)\) can also be either even or odd in the time coordinate. The even-frequency pair amplitude we define, as usual, by the equal-time amplitude, such that the even-frequency even-interband spin-singlet s-wave amplitude is \(F^s = F^+(\tau \rightarrow 0^+)\). For the component odd in time, we can still define an equal-time order parameter if we use the time derivative at equal times [3, 18, 20]:

$$F^o_\omega = \frac{\partial F^\pm_\omega}{\partial \tau}|_{\tau \rightarrow 0^+} = \frac{i}{2N_k} \sum_k \Delta \left[ \eta \sinh \left( \frac{\varepsilon_c - \varepsilon_d}{2k_B T} \right) + (\varepsilon_c - \varepsilon_d) \sinh \left( \frac{\eta}{2k_B T} \right) \right], \quad (7)$$

where \(\eta = \sqrt{(\varepsilon_c + \varepsilon_d)^2 + 4|\Gamma|^2}\). For odd-frequency pairing to appear \(\varepsilon_c \neq \varepsilon_d\) is necessary, which is true for finite \(\Gamma\). Further, when \(T \rightarrow 0\) and \(|\varepsilon_c - \varepsilon_d| > \eta\) we get \(F^o_\omega = \frac{i}{2N_k} \sum_k \Delta \frac{(\varepsilon_c - \varepsilon_d)}{\eta} \), whereas if \(|\varepsilon_c - \varepsilon_d| < \eta\), \(F^o_\omega = \frac{i}{2N_k} \sum_k \Delta \operatorname{sgn}(\varepsilon_c - \varepsilon_d)\). Odd-frequency odd-interband pairing is thus always present in a superconductor with even-interband pairing and non-identical bands [39]. Even-interband pairing and different band dispersions in turn always exist in a two-band superconductor with finite band hybridization \(\Gamma\) and different intraband order parameters. The overall factor of \(i\Delta\) in Eq. (7) is important as it gives \(\pm [F^\pm(\tau)]^* = F(\tau)\) and thus invariance under time-reversal symmetry.

Equation (7) ignored intraband pairing. While these can change the value of the odd-frequency odd-interband pair amplitude they will, in general, never destroy it, as exemplified in Fig. [1]. There we plot \(i F^o_\omega\) for a two-band superconductor on a three-dimensional (3D) cubic lattice with nearest neighbor hopping and \(\varepsilon_b = \beta \varepsilon_a\) for \(\beta = 1,4\) and \(\Delta_b = \alpha \Delta_a\) for \(\Delta_a > 0, |\alpha| \leq 1\). Let us first study the special case \(\alpha = -1, \beta = 1\), which
sublinear dependence on the band hybridization $\Gamma$. We explicitly illustrates the deep connection between $F^e$ and $F^o$. Then the diagonal band dispersions $\varepsilon_{c,d} = \varepsilon_0 + \Gamma$, intraband pairing $\Delta_{c,d} = 0$, and interband pairing $\Delta_{a,d} = \Delta_a$. If we further assume $\Gamma < \Delta_a$, the even-interband pairing amplitude is the BCS gap equation: $F^e = -\frac{\Delta_a}{\pi N \sqrt{k^2 + \Delta_a^2}}$ whereas the odd-frequency odd-interband amplitude is $F^o = iT F^e$. Red solid curve in Fig. (a) shows the linear dependence on $\Gamma$ for $\Gamma < \Delta_a = 0.5$, while deviations from $\varepsilon = -1, \beta = 1$ give a sublinear dependence on the band hybridization $\Gamma$. We also find a linear dependence on $\alpha$, as seen in Fig. (b), clearly demonstrating the robust dependence of $F^o$ on the interband pairing $\Delta_{a,d} \propto (\alpha - 1)$. The decrease in $F^o$ with increasing band-width ($\beta$) is also a sign of its connection to the even-frequency pair amplitude.

The above analytical and numerical results show that odd-frequency odd-interband pairing is extremely common in multi-band superconductors, requiring only a finite band hybridization and different intraband order parameters, as is generally always present. For example, in the presence of interband defect scattering, odd-frequency pairing should be present in the two-band superconductor MgB$_2$ [15, 16], high-temperature superconducting iron-pnictides/chalegens [11], as well as in superconducting heavy fermion compounds [12, 14]. The key to odd-frequency odd-interband pairing is the existence of even-interband pairing. Interband pairing that is not an even function in band index will not have the same effect. For example, interband pairing of the form $c^\dag_{\alpha i} d_{\beta j} d^\dag_{\alpha k^\prime} c_{\beta j^\prime}$, which constitutes an interband pair scattering mechanism [21], does not induce odd-frequency pairing.

The deep connection between parity in band index and frequency is further solidified if we consider the case of even-frequency odd-interband pairing, which for $s$-wave symmetry is necessarily a spin-triplet state. While such odd-interband pairing cannot be induced by simple band hybridization, it has been suggested for the iron-pnictides [22] and found in the proximity-induced superconducting response in topological insulators [23]. Again, ignoring any intraband pairing $\Delta_{c,d}$ in $H_{cd}$ in Eq. (3) and replacing the even-interband pairing $\Delta_{cd}$ with an odd-interband spin-triplet term we arrive at an odd-frequency even-interband spin-triplet $s$-wave pairing amplitude exactly equal to the result in Eq. (7). That is, there is a complete reciprocity between band index parity and frequency, as formally established by $TO = \pm 1$ in Table I for spin-singlet $s$-, $d$-wave or spin-triplet $p$-wave symmetries.

We have so far, exclusively worked in reciprocal space, but there are many situations where multiple superconducting orbitals, or sites, within one unit cell have to be described in real space. In this case we will let the operators $a_{i\sigma}$ and $b_{i\sigma}$ represent the (two) different orbitals in the unit cell $i$. By using $a_{i\downarrow}^\dagger b_{i\uparrow}$ and $b_{i\downarrow}^\dagger a_{i\uparrow}$ for intraorbital spin-singlet $s$-wave pairs, the derivation given above is equally applicable in this real space system. Thus odd-frequency odd-interorbital pairing will always be present as soon as there is a finite single-electron orbital hybridization of the form $a_{1\sigma}^\dagger b_{3\sigma}$ and non-identical intraorbital superconducting order parameters. The latter requirement can be fulfilled if the orbitals have different physical origins, but also if the orbitals are separated in space and there are atomic-scale variations in the material. A Josephson junction with single-electron hybridization across the junction is a prototype example of the latter. Another example is a superconductor/Bi$_2$Se$_3$ topological insulator heterostructure. The two active (Bi) orbitals in Bi$_2$Se$_3$ are separated along the $z$-axis [24, 25] and will therefore experience different superconducting pairing. We recently found numerically a complete reciprocity between parity in orbital and frequency spaces in a Bi$_2$Se$_3$/superconductor heterostructure for spin-singlet $s$-wave as well as spin-triplet $p$-wave superconductors [26]. The $PTO = \pm 1$ symmetry requirement established above provide the analytical framework for this finding.

Yet another simple example of a multi-orbital system is graphene. Intrinsic superconductivity has been proposed theoretically in graphene [26, 27] and a superconducting state has been achieved experimentally in graphene by proximity-coupling to a superconductor [30]. In graphene, the hybridization between the $p_z$-orbitals on the two carbon atoms equals the nearest neighbor hopping $t$, and therefore overwhelmingly dominates kinetic energy. Odd-frequency odd-interorbital pairing will thus be present whenever there are different superconducting intraorbital pairing order parameters $\Delta_{a,b}$ on the two sites. Since $\Delta_{a}(i) = -U_a <a_i^\dagger a_i>$ for some pair potential $U_a$, and equivalently for $\Delta_{b}(i)$, different intraorbital order parameters can be achieved by either having $U_a \neq U_b$ or by having different density of states at each site. In Fig. 2 we plot $iF^o$ for both of these cases. In Fig. 2(a) the pair potential $U_b$ is changed while $U_a$ and the local chemical potentials $\mu_a = \mu_b$ are kept fixed. The odd-frequency response is always zero for $U_a = U_b = 2t$ and is larger for higher chemical potentials, since larger density...
of states at the Fermi level cause larger even-interorbital pairing. In Fig. 2(b) we instead set $U_a = U_b$ but vary the chemical potential difference between the two sites. $F_{o,b}^o$ is zero when there is no asymmetry between the two sites, i.e., $\mu_a = \mu_b$, but is in general otherwise finite. The results in Fig. 2 show that odd-frequency pairing is present as soon as there is sublattice symmetry breaking, which in graphene can be achieved by substrate effects \[31\]. While we have here used graphene as a simple example, odd-frequency odd-interorbital pairing will be present in any non-Bravais lattice with a site-dependent superconducting state. For these systems it is the sublattice symmetry breaking that facilitates the creation of odd-frequency pairing.

Odd-frequency superconducting pairing has in the past often been associated with the appearance of sub-gap states \[4, 7, 8, 32, 33\], or even a low-energy continuum \[2, 19\]. However, for odd-frequency odd-interband pairing, we do not in general find any low-energy states. For the special case studied analytically above, i.e., Eq. \(a\) with $\Delta_{c,d} = 0, \Delta_{cd} = \Delta_a$ and $\varepsilon_{c,d} = \varepsilon_a \pm \Gamma$, we find the eigen energies $E = \pm (\sqrt{\varepsilon_a^2 + \Delta_a^2} \pm \Gamma)$, and thus zero energy states for $\Gamma \geq \Delta_a$. However, there is no stable superconducting state for $\Gamma \geq \Delta_a$. The absence of pure interband superconductivity with zero energy states has also been established in other systems \[34, 35\]. The absence of sub-gap states is further confirmed by numerically solving the original Hamiltonian $H_{ab}$ in Eq. \(a\). For isolated bands, i.e., $\Gamma = 0$, we have the BCS energy gap relation $E_g = \Delta^o_{a,b}$ in each band, where the superscript $sc$ stands for the self-consistent result found for fixed pair potentials $U_{a,b}$. For finite $\Gamma$ we always find $E_g \geq \min(\Delta^o_{a,b})$, with $\Delta^o_{a,b}$ modified in the presence of a finite band hybridization. Thus, the energy gap is never smaller than the intraband BCS gaps. The lack of low-energy signatures of the odd-frequency odd-interband pairing is similar to the odd-frequency pairing behavior in topological insulator/superconductor heterostructures \[33, 50\] and in heavy-fermion compounds \[57\]. Together these results demonstrate that odd-frequency pairing often have a frequency dependence which do not generate sub-gap states.

In Eq. \[1\] we assumed an even-frequency order parameter and showed how it induces an odd-frequency pair amplitude. An intriguing possibility is that the order parameter in some known multi-band superconductor has an odd-frequency dependence, but that it induces a finite even-frequency pair amplitude, which is mistaken to also be the (even-frequency) order parameter. One example might be the heavy fermion compounds, which have been propose to have an odd-frequency order parameter \[32\].

In summary, we have found the general symmetry rule for spatial parity $P$, time reversal $T$, and orbital parity $O$ for multi-band superconductors to be $PTO = 1(-1)$ for spin-singlet (triplet) pairing. Within a generic microscopic model of multi-band superconductors we have shown that odd-frequency pairing always exists in the form of odd-interband (orbital) pairing if there is finite band hybridization and non-identical intraband order parameter strengths. The key to odd-frequency odd-interband pairing is the existence of even-frequency even-interband pairing, consistent with the general symmetry requirements. In fact, we find a complete reciprocity between parity in band (orbital) index and frequency for the superconducting pair amplitude, which naturally follows from $TO = 1$ for spin-singlet $s$-wave (or spin-triplet $p$-wave) pairing. The $s$-wave nature makes the odd-frequency pairing resistant to disorder scattering. These results show that odd-frequency pairing is present in the bulk state of many superconductors, requiring no external symmetry breaking such as interfaces or magnetic fields.

We are grateful to E. Abrahams, D. Scalapino and J. R. Schrieffer for numerous discussions on the nature of odd-frequency superconductivity and acknowledge funding from the Swedish research council (VR) and the European Research Council under the European Union’s Seventh Framework Programme (FP/2007-2013)/ERC Grant Agreement DM-321031. Work at Los Alamos was supported by U.S. DoE Basic Energy Sciences for the National Nuclear Security Administration of the U.S. Department of Energy under contract DE-AC52-06NA25396.

[38] For odd-orbital (antisymmetric) projection we trace $\Delta_{\alpha \beta}(r, \tau) = \sum_{ab} \epsilon_{ab} \Delta_{\alpha \beta,ab}(r, \tau)$ and for even-orbital (symmetric) projection we trace $\Delta_{\alpha \beta}(r, \tau) = \sum_{ab} (\tau^I \cdot \tau^Y)_{ab} \Delta_{\alpha \beta,ab}(r, \tau)$, $I = 1, 2, 3$ is the vector index in the “orbital” space, and $\tau$ are Pauli matrices operating in orbital space.
[39] Technically both bands cannot also be half-filled, i.e. particle-hole symmetry needs to be broken.
