Erythropoietin (EPO), named after its role in hematopoiesis, is also expressed in mammalian brain. In clinical settings, recombinant EPO treatment has revealed a remarkable improvement of cognition, but underlying mechanisms have remained obscure. Here, we show with a novel line of reporter mice that cognitive challenge induces local/endogenous hypoxia in hippocampal pyramidal neurons, hence enhancing expression of EPO and EPO receptor (EPOR). High-dose EPO administration, amplifying auto/paracrine EPO/EPOR signaling, prompts the emergence of new CA1 neurons and enhanced dendritic spine densities. Single-cell sequencing reveals rapid increase in newly differentiating neurons. Importantly, improved performance on complex running wheels after EPO is imitated by exposure to mild exogenous/inspiratory hypoxia. All these effects depend on neuronal expression of the Epor gene. This suggests a model of neuroplasticity in form of a fundamental regulatory circle, in which neuronal networks—challenged by cognitive tasks—drift into transient hypoxia, thereby triggering neuronal EPO/EPOR expression.
Erythropoietin (EPO) is a hypoxia-inducible growth factor in mammalian kidney, named after its role in hematopoiesis. Unexpectedly, both EPO and its receptor (EPOR) were later detected in the brain, where they are upregulated by injury conditions. High-dose recombinant human (rh) EPO, a drug in clinical use for anemic patients, exerts neuroprotective and neuroregenerative effects that are independent of the hematocrit, which is mechanistically unexplained. Moreover, rhEPO improves cognitive function and reduces gray matter loss in a range of neuropsychiatric conditions. Even in healthy mice, rhEPO treatment improves cognition, which is associated with enhanced hippocampal long-term potentiation. Surprisingly, rhEPO increases the number of mature hippocampal pyramidal neurons without underlying effect on cell proliferation or cell death. This effect is mediated in neurons mainly by JAK-STAT, PI3K/AKT/PKB, Ras-MEK, and ERK1/2, as well as NF-kB; pathways widely comparable to the hematopoietic system. This raises the question whether the expression of EPO and its receptor serves a physiological function in the nervous system, and what could be the triggering factors of EPO expression under physiological conditions.

Results

Generation of pyramidal neurons in adult mice and amplification by rhEPO. First, we developed a method to directly label and quantify newly generated neurons in the hippocampal cornu ammonis (CA) field of adult mice. This was possible by permanently labeling all mature pyramidal neurons present at P27 using a tamoxifen-inducible reporter gene in NsexCreERT2::R26R-tdT mice (Fig. 1a, b). Thus, all neurons differentiating and maturing after termination of the tamoxifen-induced Cre recombination lack tdTomato, but can be positively identified by Ctip2, a specific marker of pyramidal neurons, thereby revealing adult ‘neurogenesis’ independent of DNA synthesis.

Immediately after tamoxifen induction, at P28, the number of such unlabeled (tdTomato−, Ctip2+) pyramidal neurons, quantified for control purposes, was <3% of all Ctip2+ cells. When rhEPO treatment was initiated at P28 as described, and mice were analyzed at P55, we found a considerable number of newly differentiated (tdTomato−/Ctip+) neurons in CA1, without evidence by 5-Ethynyl-2’-deoxyuridine (EdU) incorporation of proliferating precursors, as we reported previously. Upon rhEPO treatment, the number of pyramidal cells was higher compared to placebo, but even untreated mice revealed a remarkable increase in new neurons (Fig. 1c).

Strikingly, when we applied the same rhEPO treatment to older mice (age 3 months), we noted that EPO treatment also enhanced the dendritic spine density in pyramidal neurons at both P55 and 4 months (Fig. 1e–i). The analysis of spine morphology (Fig. 1j–l) showed an increase in stubby immature spines and a trend toward more mature mushroom spines. Reflecting the increased pyramidal neuron number, we also noted a higher density of Map2 immunoreactive primary dendrites in the stratum radiatum (Fig. 1m–o).

Immediate differentiation response of neuronal precursors to rhEPO. We employed single-cell transcriptome analysis (scRNA-seq) to explore the immediate response of cells in CA1 to rhEPO, detectable 6 h after a single intraperitoneal (i.p.) injection of 5000U rhEPO/kg (Fig. 2, Supplementary Figs. 1–3, Source Data File). This revealed alterations in the cell cluster composition as defined by gene expression profiles, with more cells in the immature glutamatergic differentiation cluster after rhEPO (Fig. 2a–d). Markers that characterize this cluster include doublecortin (Dco), transducin-like enhancer family member 4 (Tle4), T-box brain1 (Tbr1), rhombomeric somatocoma 2-associated transcript (Rmst), SRY-Box 5 (Sox5), DNA-binding protein SATB1 (Satb1)), ELAV-like neuron-specific RNA-binding protein 4 (Elavl4), fucosyltransferase9 (Fut9), CUGBP Elav-like family member 4 (Celf4), and heparan sulfate-glucosamine 3-sulfotransferase4 (Hssts4). For two of them, Tle4 and Tbr1, in situ validation of protein expression by immunohistochemistry (IHC), predominantly in Ctip2− neurons (confirmed by double labeling) at P29, i.e., 24 h after a single injection of EPO/placebo, exemplifies the distinct EPO effect (Fig. 2e). Note that Tbr1+ neurons upon EPO are rapidly and strongly detected in CA1 at P29, but only rarely anymore at P55. Tbr1+ cells in dentate gyrus serve as positive control for both time points (Supplementary Fig. 3e). Other neuronal clusters and non-neuronal cell types were not obviously different between treatment groups at 6 h (Supplementary Fig. 3b).

To further investigate the EPO-induced effects on cell differentiation, we performed a trajectory (pseudotime) analysis on cells in the immature glutamatergic cluster and its neighboring cluster, mature glutamatergic1, in Monocle2 (Fig. 2f; list of differentially expressed genes between these two clusters given in Source Data File). The analysis confirmed the immature identity of cells in the immature glutamatergic cluster, reflected by a homogeneously low pseudotime of almost all cells in this cluster, which was significantly lower as compared to cells in the mature glutamatergic1 cluster (Fig. 2g). After post hoc exploratory removal of immature cells with high pseudotime (>15, n = 10), the increase in immature cells upon EPO still remained significant (p = 0.039; Fisher’s exact test, one sided). Even if the immature cells with high pseudotime (>15) were reassigned to the mature glutamatergic cluster, a significance level of p = 0.041 was obtained. Importantly, we observed a generally lower pseudotime upon EPO, independent of cluster assignment, further supporting our observation of an increase in immature cells and excluding a mere ‘clustering artifact’ (Fig. 2h). Also, reclustering in Monocle2 of cells from the two clusters revealed a robust detection of the immature cluster across methods (Seurat and Monocle2; Supplementary Fig. 3a) and a robustly increased number of immature cells upon EPO as compared to placebo treatment, independent of the analysis platform (p = 0.0008). For further validation of the immature identity of these cells see Supplementary Fig. 3c, d.

Together, these data provide supportive evidence of an immediate effect of EPO on pre-existing precursors to instantaneously initiate neuronal differentiation, thereby rapidly increasing the numbers of cells in the immature glutamatergic differentiating cluster. Expectedly, EPO and EPOR were not detected by scRNA-seq due to their very low expression level, a known drop-out effect in scRNA-seq data.

Elevated expression of EPO and EPOR by pyramidal neurons upon CRW. Searching for the physiological significance of these responses, we explored whether EPO and EPOR are endogenously expressed by pyramidal neurons. Using a highly sensitive in situ hybridization (ISH) method, capable of detecting even single mRNA molecules, we identified both EPO and EPOR transcripts in pyramidal neurons of the hippocampal CA1 region (Fig. 3a–d). The overall mRNA abundance in the hippocampus...
was higher than in cortex and other brain regions. Interestingly, when mice were placed into cages with complex running wheels (CRW)\textsuperscript{26}, a cognitive challenge that stimulates intricate motor learning and coordination, only 5–9 h of running in the dark phase were sufficient to upregulate the expression of EPO and EPOR transcripts in pyramidal neurons (Fig. 3a–d).

Permanent labeling of hypoxic neurons in CA1 by CRW exposure. We therefore wondered which mechanism would lead to the swift upregulation of EPO in pyramidal neurons upon cognitive challenge. In the kidney, it is hypoxia and hypoxia-inducible factors (Hif), which are well known to induce EPO expression\textsuperscript{1,2,7,27}. We therefore hypothesized that cognitive
Fig. 1 EPO increases number of pyramidal neurons and spine density in the CA1 region of the hippocampus. a Experimental design to determine the effect of EPO on neuron numbers: two cohorts of NexCreERT2::tdTomato mice (starting at age P23 or month 3) were administered tamoxifen (at P23: 5× i.p.; at month 3: 10× i.p.), followed by placebo or EPO (5000IU/kg; 11× i.p.) on alternate days for 3 weeks. b Representative images of tdTomato (red) and Cre2p (green; excitatory neuronal marker) staining in CA1 of placebo or EPO-treated mice. White arrows indicate newly generated neurons. c, d Quantification of newly generated neurons (Cre2p+/tdTomato−) in CA1 of P55 c and −4-month-old mice d treated with placebo or EPO. Data from n = 5/8 (placebo; 1c/d) and n = 6/8 (EPO; 1c/d) mice. e Experimental design to determine the effect of EPO on dendritic spine number and morphology: Thy1-EYFP mice (starting at age P28 or month 3) were treated with placebo or EPO (11× i.p.) on alternate days, for 3 weeks. f Representative images of EYFP (green) expression in principal apical dendrites in CA1 of placebo or EPO mice. g–i For P55 and −4-month-old mice, total number of spines (per µm) are given as bar graphs and, additionally, as line graphs presenting their distance from the soma. Data from n = 5/6 (placebo; P55/4 months) and n = 6 (EPO) mice (6 cells/mouse analyzed). j–l Based on the morphology (illustrated as green insets), the number of thin j, stubby k, and mushroom l spines (per µm) were sub-quantified. m Representative image of the quantification method employed for determining the number of dendrites using dendritic marker Map2 (red) in CA1 stratum radiatum (SR); stratum pyramidale (SP). White boxes denote areas of measurements. n Representative images of Map2 (red) staining in −4-month-old mice treated with placebo or EPO. o Quantification of Map2− dendrites in P55 and −4-month-old mice treated with placebo or EPO. Data from n = 5/6 (placebo; P55/4 months) and n = 5/6 (EPO; P55/4 months) mice. Within bars, mouse n numbers indicated; mean ± SEM presented; two-tailed Student’s t-test; scale bars: b 50 µm; f 10 µm; m 20 µm; and n 10 µm. Source data underlying graphs c, d, g–l, and o are provided as a Source Data File.

challenge, such as learning of complex motor tasks, is associated with neuronal activity that requires more oxygen than present in the normal steady state. This could induce a mild (transient) endogenous hypoxia as a potential signal underlying upregulated expression of EPO in highly active pyramidal neurons. To test this hypothesis, we asked whether ‘functional hypoxia’ can be detected in the brain after cognitive challenge, such as complex wheel running. To this end, we created a novel transgenic mouse for the ubiquitous expression of a chimeric fusion protein between the tamoxifen-inducible CreERT2 recombinase and the oxygen-dependent degradation (ODD) domain of Hif-1α. In mice bearing this CreERT2-ODD transgene, driven by the CAG promoter, ‘fate mapping’ and identification of (transiently) hypoxic cells is possible with the tdTomato reporter (CAG-CreERT2-ODD::R26R-tdTomato). Indeed, exposing these mice after tamoxifen injection to CRW over one night, we determined a distinctly increased number of ‘ODD-labeled’ pyramidal neurons in the CA1 region when compared to non-runners. This indicates that a new challenging task has led to more (transiently) hypoxic neurons, which became permanently labeled. Parallel quantification of cFos expression as neuronal activity marker revealed a tendency of increased cFos labeling upon CRW (Fig. 3e–h), but no double labeling with ODD-tdTomato. The latter likely occurs too late in a respective cell, i.e., when its immediate early gene (cFos) expression has already disappeared. In contrast, after only 4 h of CRW, cFos labeling was obvious, but no ODD-tdTomato labeling yet detected (cFos+ cells: non-runners 40.1 ± 20.8, n = 3; CRW 143.3 ± 24.4, n = 7; p = 0.034, mean ± SEM). Additional confirmation of hypoxic cell labeling by ODD-tdTomato was obtained using pimonidazole, resulting in findings similar to a previous report on heart (Supplementary Fig. 4).

EPO treatment strongly increases motor learning and endurance. To further address the potential of rhEPO to lastingly improve cognitive performance, we treated juvenile mice with our protocol that results in ~20% more pyramidal neurons (starting at P28, i.p. injection of rhEPO/placebo every other day for 3 weeks, followed by a 1-week break). Afterward, the running-naive mice were transferred to cages containing CRW. During the initial learning phase, a rise in performance was observed, clearly dissociating EPO from placebo-treated mice after just a few hours, followed by enhanced endurance over the whole night.

Deletion of neuronal EPOR attenuates EPO-/hypoxia-induced motor learning. Theoretically, the EPO-induced increase in hematocrit could account for this enhanced performance. To rule this out and to explore whether pyramidal EPOR is mediating this effect, we deleted the Epor gene from pyramidal neurons (NexCre::EpoRfl/fl; Supplementary Fig. 5). More details on the generation of this conditional Epor allele, its recombination with different Cre-lines, and a comprehensive phenotype analysis will be described elsewhere (manuscript in preparation). As delineated in Fig. 4a–c, the remarkable rise in performance of wild-type (WT) mice following EPO treatment reported above was well replicated, whereas EPOR-cKO mice failed to show any noticeable effect of EPO treatment on CRW performance (i.e., complex motor learning and endurance). Placebo-treated EPOR-cKO did not appreciably differ from WT mice (Fig. 4c, inset). The behavioral phenotype of EPOR-cKO mice strongly suggested that also neuronal complexity, i.e., dendritic spine density of pyramidal neurons, would be affected by EPOR deletion. Indeed, Golgi staining revealed that lack of EPOR in pyramidal neurons prevented the EPO-induced increase in dendritic spines (Fig. 4d, e).

Mild inspiratory hypoxia acts synergistically with cognitive challenge. Since learning to run on CRW leads to endogenous (‘functional’) hypoxia in pyramidal neurons, as demonstrated by ODD labeling, and since pyramidal EPO and EPO mRNAs are upregulated by functional hypoxia, we wondered whether CRW exposure for several weeks would (similar to rhEPO treatment) also lead to more pyramidal neurons. Moreover, would a sustained exposure of mice to a mild exogenous (inspiratory) hypoxia (12% O2), when coinciding with running activity, result in similar or even synergistic effects, i.e., better learning performance and more neurons in the stratum pyramidale? In the respective large-scale, multi-arm experiment over 3 weeks, we indeed detected improved motor learning and endurance on the CRW of mice under mild hypoxia when compared to normoxia (Fig. 4f–k). To unequivocally demonstrate that the neuronal EPO/EPOR system is responsible for the observed effects, we employed again our mice with targeted deletion of the Epor gene in pyramidal neurons. In fact, lack of EPOR in pyramidal neurons resulted in a distinct reduction of the learning curve slope over time, both under normoxic and hypoxic conditions, when compared to the respective WT controls. Also, non-running EPOR-cKO mice have already less pyramidal neurons independent of hypoxia (normoxia: 7834.07 ± 223.18 in cKO versus 9377.48 ± 1143.34 in WT; p = 0.0012) and fail to show the increase in pyramidal neurons found in WT mice upon running with or without hypoxia (Fig. 4f–k).
Expression of cFos marks newly differentiated neurons. Under both normoxic and hypoxic conditions, we counted more recently differentiated (EdU negative) pyramidal neurons in runners than in non-runners in the hippocampal CA1 field. We thus wondered whether the newly differentiated pyramidal neurons, generated in mice placed into CRW cages, are functional. To address this question, we challenged animals for 3 weeks in CRW (with or without mild inspiratory hypoxia) but moved them first back to regular cages for 1 week, in analogy to the rhEPO treatment scheme. Then, we re-exposed the mice to CRW for only 4 h at the beginning of their dark phase. Immediately thereafter, they were sacrificed and brains processed for IHC. As readout of neuronal activity and functional integration, cFos expression was used again and found to be enhanced following hypoxia, and in

Fig. 2 Transcriptome analysis (scRNA-seq) demonstrates an immediate increase in neurodifferentiation upon EPO application. a Experimental design of WT C57Bl6 mice (n = 3 per group), treated at P28 with a single i.p. injection of placebo or EPO (5000IU/kg), followed by isolation of the CA1 region after 6 h and processing for DropSeq analysis (processing of biological replicates performed separately, followed by pooling for graphical presentation and final analysis), as well as after 24 h for immunohistochemistry (figure created by Debia Wakhloo). b Visualization of hippocampal CA1 cell clusters using t-distributed stochastic neighbor embedding (tSNE). Each color represents a cluster of specific cells, characterized by a defined gene expression profile. c Individual cells derived from either EPO (red) or placebo (black)-treated mice are denoted. d Percentage of cells in the respective glomerular clusters per treatment condition (EPO: n = 583, placebo: n = 390); two-tailed Fisher’s exact test. e Representative images and quantification of Tbr1 and Tle4 staining (immature neuronal markers) in CA1 of mice at P29, i.e., 24 h after a single injection of EPO. Within bars, mouse n numbers indicated; mean ± SEM presented; two-tailed student’s t-test. f Trajectory analysis in Monocle2 of cells in the ‘Mature Glutamatergic1’ and the ‘Immature Glutamatergic’ cluster colored by pseudotime (the darker the more mature). g Trajectory colored by cell identity. Bar graph indicates average pseudotime of the respective clusters; mean ± SEM; two-tailed Mann–Whitney U test. h Trajectory colored and split by placebo (black; left) versus EPO treatment (red; right). Bar graph shows average pseudotime of cells in the respective treatment groups; two-tailed Mann–Whitney U test; mean ± SEM; see also Supplementary Figs. 1-3. Source data underlying graph e are provided as a Source Data File.

Discussion

Taken together (Fig. 5), we have discovered that EPO - experimentally and clinically shown to improve cognition3–17 - stimulates a previously unrecognized mechanism of cellular neuroplasticity. Specifically, rhEPO (when peripherally administered) enters the brain, where it mimics the effects of endogenous neuronal EPO/EPOR signaling, stimulating dendritic spine formation on mature cells, and the differentiation of new pyramidal neurons from pre-existing (non-proliferating) precursors, the identity of which is currently unknown.

The EPO-responsive cells undergoing adult neurogenesis likely have no defining single genetic marker, suitable for CreER-based lineage tracing (unlike the EPO-responsive OPC17). Not even direct transdifferentiation of endothelial and astroglial cells or dedifferentiation of neurons can be completely excluded at this point. Jak2-Stat5 signaling, however, a pathway important for neuronal EPOR effects18,20, is known in various tissues to induce point. Jak2-Stat5 signaling, however, a pathway important for direct transdifferentiation of endothelial and astroglial cells or dedifferentiation of neurons can no longer contribute to adaptive increase in performance.

We hypothesize that the entire precursor cell lineage that is ready to differentiate toward pyramidal neurons in adult mice remains in ‘flow’. Similar to adaptive metabolic pathways, in which the ‘flux’ of metabolites matters more than the different steady-state concentrations, also in the proposed neuronal lineage progression, the EPO-responsive progenitor cells may never constitute abundant clusters in a cross-sectional steady-state analysis. This is remarkably similar to the effects of EPO on multiple precursors at different stages in the hematopoietic system1,30–32.

Pyramidal neurons, when challenged by novel tasks, undergo mild hypoxia, as detected here by ‘ODD labeling’, using hypoxia reporter mice. This activity-induced ‘functional hypoxia’ stimulates endogenous EPO expression by pyramidal neurons. In parallel, we find also EPOR expression enhanced, caused either directly by hypoxia33 or by EPO in an auto/paracrine manner34. When EPOR expression is deleted from pyramidal neurons, the endogenous EPO/EPOR system can no longer contribute to adaptive increase in performance.

Contrary to popular viewpoints that hypoxia is detrimental, recent reviews also consider beneficial effects and protection against cognitive dysfunction35,36. Our data using CRW indicate that hypoxia can act as driving force of long-lasting cellular neuroplasticity, complementing synaptic plasticity. Neuronally produced EPO/EPOR likely constitutes an auto/paracrine mechanism, possibly in concert with other hypoxia-inducible genes, like vascular endothelial growth factor, which has previously also been reported to enhance cognition37. We suggest a model of an intrinsic EPO/EPOR-mediated mechanism of cellular neuroplasticity (Fig. 5), in form of a fundamental regulatory circle, which can explain the remarkable pro-cognitive effects of rhEPO, consistently found in humans and rodents, health and disease9,10,12,14–16,38.

A recent study documented EPO mRNA in different neural cell types in the embryonic brain (mouse organogenesis cell atlas—MOCA39). The extraordinarily low expression of EPO and EPOR in the adult brain may explain why this system has previously not been rigorously studied. So far, we have focused on the hippocampal CA1 region, where we had obtained first evidence of substantially increased neuron numbers after rhEPO treatment17. CA1 is involved in spatial pattern association and different facets of memory formation and consolidation40. Future studies will have to address EPO/EPOR functions in other CNS regions, including cortical areas known to be also engaged in CRW learning41, as well as neuron–glial interactions.

‘Adult neurogenesis’ from pre-existing precursors without proliferation extends the concept and pivotal work from many groups who discovered adult neurogenesis in distinct brain regions based on the selective labeling of proliferating cells in S-phase42–48. More complex than oligodendrogenesis from pre-existing precursors49, multiple neuronal progenitors may be relevant for maintaining neuron numbers in steady state, for adjustment to demand, and for rapid regenerative processes. The genetic approach of EPOR deletion in pyramidal neurons, together with the discovery of ‘functional hypoxia’ in the behaving brain, allowed us to propose a novel working model (Fig. 5). This model may add to our present concepts of neuroplasticity and adult neurogenesis.

Methods

Experimental models and mouse genetics. All experiments were approved by and conducted in accordance with the regulations of the local Animal Care and Use Committee (Niedersächsisches Landesamt für Verbraucherschutz und Lebensmittelsicherheit, LAVES). WT C57Bl6N (Charles River), NexCreERT220, R26rtomato50, Thy1-YFP (Jackson Laboratory, 003782), CAGCreERT2-ODD54, NexCre14, and EPOR–floxed (EPORfl) mice were used for the experiments. Juvenile (P23) and adult (3 months old) mice were used in this study. For genetic labeling of projection neurons, NexCreERT2 mice were bred with Rosa26 floxed-stop tdTomato (R26R-tdTomato) reporter mice to generate NexCreERT2R26R-tdTomato mice. For labeling cells undergoing hypoxia, CAGCreERT2-ODD mice were employed58. Briefly, a fusion protein consisting of the ODD domain of Hif-1a and a ubiquitous CAGCreERT2 is expressed upon tamoxifen induction.

CAGCreERT2-ODD were bred with R26R-tdTomato to generate CAGCreERT2-ODDtdTomato reporter mice. Upon tamoxifen induction, cells are reversibly labeled with tdTomato containing stabilized Hif-1a. NexCre: Eporfl mice were generated to specifically delete Epor in projection neurons. For the generation of Eporfl mice, embryonic stem cells (ES) harboring an engineered allele (Eporfl) were acquired from the Knockout Mouse Project (KOMP, University of California, Davis CA 95618, USA). ES cells were microinjected into blastocysts derived from C57Bl6N mice and the embryos were transferred to pseudopregnant foster mothers, yielding chimeric males. For ES clone EP0D3166_5_A03, germline transmission was achieved upon breeding with...
C57BL/6N females, generating mice harboring the Epor<sup>tm1a(KOMP)Wtsi</sup> allele (termed EporlacZ-neo). The lacZ-neo cassette was excised in vivo upon interbreeding with mice expressing FLIP recombinase (129S4/SvJaeSor-Gt(ROSA)26Sortm1(FLP1)Dym/J; backcrossed into C57BL/6N), yielding mice carrying the Epor<sup>tm1c(KOMP)Wtsi</sup> allele (termed Epor<sup>fl</sup>ox). To recombine the Epor gene specifically in projection neurons, exons 3–6 were excised in vivo upon appropriate interbreedings of Epor<sup>tm1c(KOMP)Wtsi</sup> mice with mice expressing Cre recombinase under control of the Nex1/Neurod6 promoter<sup>51</sup>, generating mice carrying the Epor<sup>tm1d(KOMP)Wtsi</sup> allele (NexCre::Epor<sup>fl/fl</sup> mice).

All mice were housed in a temperature controlled environment (21 ± 2 °C) on a 12 h light–dark cycle with food and water available ad libitum. Male mice of the same age were used for the experiments, unless stated otherwise. All animals were genotyped before the start of each experiment. Detailed PCR protocols are available on request.

---

**Fig. 3 Expression of the EPO/EPOR system in pyramidal neurons shown by ISH and its upregulation by functional hypoxia.**

**a** Experimental design of WT C57Bl6 mice exposed to no running (NR) or voluntary running on CRW at P55 for 5, 9, or 13 h. ISH was performed on CA1 regions (figure created by Debia Wakhloo).

**b** Representative ISH images of CA1 regions of non-runners (NR) and runners (CRW), demonstrating EPO and EPOR mRNA expression in pyramidal neurons (brown spots). As positive controls for EPO/EPOR mRNA expression, sections of kidney (P55) and heart (E14.5) from WT C57Bl6 mice are presented.

**c, d** Quantification of total number of EPO or EPOR mRNA spots in CA1 of non-runners (NR) and runners (CRW), shown at 5, 9, and 13 h; mean and range shown; two-way ANOVA; n numbers indicated within bars; scale bars in b: 10 µm; for heart 5 µm.

**e** Experimental design to determine the effect of running on the induction of functional hypoxia in the CA1 region. CAGCreERT2-ODD::tdTomato mice were administered tamoxifen at P55 of age and exposed to either no running (NR) or overnight voluntary CRW.

**f** Representative images of neuronal marker NeuN (white), tdTomato (red; labeling hypoxia), and cFos (cyan) in non-runner (NR) and runner mice (CRW); scale bars 100 µm (left); 10 µm for magnifications.

**g, h** Quantification of hypoxic neurons (tdTomato<sup>+</sup>) and active neurons (cFos<sup>+</sup>) in CA1 after CRW versus NR overnight (12 h); mean ± SEM; two-tailed Student’s t-test; data from n = 7 (non-runners, NR) and n = 8 (CRW) mice. Source data underlying graphs c, d, g, and h are provided as a Source Data File.
Mouse treatment. Tamoxifen: Tamoxifen solution (10 mg/ml) was freshly prepared by dissolving tamoxifen freebase (Sigma) in corn oil (Sigma) at room temperature (RT) for 45 min. Postnatal CreERT2 activity in NexCreERT2 mice was induced by a total of five i.p. injection of 100 mg/kg tamoxifen over the course of 3 days in juvenile mice. For CreERT2 induction in adult NexCreERT2 mice, a single i.p. injection of 100 mg/kg tamoxifen was sufficient.

EPO: Male mice were i.p. injected with 5000 IU/kg rhEPO (NeoRecormon, Roche) or placebo (solvent solution, 0.01 ml/g). At 48 h after the last tamoxifen injection, EPO/placebo treatment was initiated in P28 or 3-month-old NexCreERT2, Thy1-YFPH and also in P28 old WT and NexCre::EPOR<sup>fl/fl</sup> mice, and carried out every other day for 3 weeks. For DropSeq analysis, EPO was administered once followed by tissue collection 6 h later. Additionally, for labeling of proliferating cells, NexCreERT2 mice obtained EdU (0.2 mg/ml; ThermoFisher) via drinking water (exchanged on all alternate days).
Fig. 4. Targeted deletion of EPOR in pyramidal neurons attenuates EPO/hypoxia-induced motor learning. a Experimental design. b Total distance run by placebo (black) and EPO (red) treated WT mice. c Total distance run by WT (red) and EPOR-cKO mice (purple) following EPO; inset shows for comparison total distance run by WT (black) and EPOR-cKO mice (blue) upon placebo. d Representative images of hippocampal section processed with GolgiStain™ (scale bar: 200 μm), CA1 pyramidal neurons (scale bar: 20 μm), and mid-apical dendrites (scale bar: 1 μm). e Quantification of dendritic spines in WT and EPOR-cKO mice treated with placebo or EPO. f Experimental design. WT and EPOR-cKO mice were exposed to NR or CRW under normoxia (21% O2) or inspiratory hypoxia (12% O2) for 4 h. (cFos activation) before being sacrificed at PSS (results in g–k). NexCreERT2:tdTomato mice were injected with tamoxifen (5 i.p. injections at P23) and exposed to same experimental paradigm (results in i–p). g CRW curves over 17 nights (normalized to mean distance over first three nights) of WT mice exposed to continuous inspiratory normoxia versus hypoxia. h–k Effect of EPOR deletion in pyramidal neurons: h CRW curves of WT and EPOR-cKO mice exposed to normoxia and h quantification of their Ctip2+ cells in CA1 (normalized to NR controls). j CRW curves of WT and EPOR-cKO mice exposed to inspiratory hypoxia, and k quantification of their Ctip2+ cells in CA1 (normalized to NR controls). l Representative images of cFos+ neurons (cyan) in NR and CRW mice exposed to normoxia or hypoxia (scale bar: 25 μm). m Quantification of newly formed neurons (Ctip2+/tdTomato−) in NR and CRW mice exposed to hypoxia or normoxia. n, o Quantification of active neurons classified as pre-existing neurons (cFos+/Ctip2+ or tdTomato−) or as newly formed neurons (cFos−/Ctip2+ or tdTomato+). p Presentation of the small percentage of pre-existing neurons among cFos− neurons. Data given as mean ± SEM; two-tailed Student’s t-test (i & k) or two-way ANOVA; mouse n numbers in panels. Source data of graphs b, c, e, g–k, and m–p provided as Source Data File.

Hypoxia: The hypoxia chamber was designed in cooperation with Cov Laboratory Products Inc (Grass Lake, MI, USA) with the dimensions 164 cm × 121 cm × 112 cm. The system includes an air filtration system consisting of carbofilm and activated charcoal. The oxygen and carbon dioxide levels were constantly detected and controlled via online monitoring. A gradual reduction of 3% oxygen per day resulted in 12% oxygen level in 3 days and was maintained until the end of the experiment. During the course of the experiment, mice were treated with EdU via drinking water as described above.

Complex running wheels (CRW). Post weaning, mice were single-housed and tamoxifen treatment was initiated for NexCreERT2:tdTomato mice (described above). NexCreERT2:tdTomato and NexCre:EpRe825 mice were divided into four groups and monitored for 17 days. Groups included (1) normoxic room conditions (at 21% O2) in standard cages, (2) normoxic conditions with voluntary running on CRW, (3) hypoxic conditions (hypoxia chamber to 12% O2) in standard cages, and (4) hypoxic conditions with voluntary running on CRW. CRW (TSE Systems, Bad Homburg, Germany) is characterized by randomized missing bars as previously described.24,44,45 CRW (cFos−/tdTomato−) in CA1 of mice quantified in m, p Presentation of the small percentage of pre-existing neurons among cFos− neurons. Data given as mean ± SEM; two-tailed Student’s t-test (i & k) or two-way ANOVA; mouse n numbers in panels. Source data of graphs b, c, e, g–k, and m–p provided as Source Data File.

Golgi-Cox staining. Mice were anesthetized and decapitated. The brain was removed, shortly rinsed in PBS, and processed with the ND Rapid GolgiStain™ Kit (FDNeuroTechnologies, PK401) according to the manufacturer’s instructions. After impregnation, the brains were embedded in 2% Agar in PBS and cut in 100 μm coronal sections with a vibratome (Leica, VT 1000 S) and placed on gelatin-coated glass slides (FDNeoTechdoges, PO101). The slices were stained and dehydrated as described in the kit protocol. Slices were mounted with Permount (ThermoFisher).

Imaging and analysis. Pyramidal neurons: Imaging was performed using the Andor Eclipse TiE microscope system (Nikon, Tokyo, Japan) with a 40× objective (Plan APO λ 40×, NA = 0.95) to image the hippocampal layers. Ctip2+ cells among CA1 pyramidal neurons were manually counted. Ctip2+ cells were characterized as newly generated neurons. Quantifications are expressed as number of newly generated neurons divided by the total area of CA1 stratum pyramidale (mm²). For Ctip2+ staining, a total of 16 hippocampi with 8 sections per animal were used. Quadruple (tdTomato, Ctip2, cFos, and EdU) staining was acquired with a TCS SP8 II System (Leica) equipped with a 20× objective (NA = 0.70) and a 3.5× additional digital zoom to investigate the hippocampal layers. Ctip2−/tdTomato− cells were imaged. The tdTomato+ cells were characterized as neurons undergoing hypoxia and manually quantified. Quantifications are expressed as number of hypoxic neurons divided by the total area of CA1 stratum pyramidale (mm²). A total of ten hippocampi with five sections per animal were used. The cFos− cells were also analyzed as described above. For Map2+ dendritic density analysis, the stratum radiatum of the CA1 region was imaged using a laser scanning confocal microscope (Leica TCS SPE). Per animal, three dorsal hippocampal slices were selected starting at bregma −1.58 mm. Confocal z-stacks (0.38 μm intervals) of whole sections were taken using a 63× objective (NA = 1.40). Per hippocampus, three images were captured, and four fields of the dimension 36.67 μm × 36.67 μm were analyzed in each image (total 36 fields per animal). Images were processed using Fiji software and Map2+ principal apical dendrites were manually quantified. The quantifications are expressed as number of Map2+ dendrites divided by the area of each image (1344.7 μm²).

Dendritic spines: Images were captured using a 63x oil immersion objective (NA = 1.40) and a 3.5× additional digital zoom to investigate the first 200 μm of the principal apical dendrite in segments of 50 μm. Confocal z-stacks (0.38 μm
1.5 times the average length of the neck) and the total length of the protrusion was <1 μm and no neck is observed; (2) mushroom, when a clear morphological transition was observed between the does and the proximal three-quarters of the microvilli.

Integration of new neurons

Panels illustrate the suggested cellular mechanisms and effects of EPO/EPOR in CA1 (hypotheses and respective figure created by Hannelore Ehrenreich).

Fig. 5 Comprehensive working model of EPO function in the brain. Panels illustrate the suggested cellular mechanisms and effects of EPO/EPOR in CA1 (hypotheses and respective figure created by Hannelore Ehrenreich).

**a** Functional challenge of pyramidal neurons (blue) via, e.g., learning of new complex tasks provokes physiological hypoxia of the involved neurons. Hypoxia in turn induces neuronal production/release of EPO, which initiates differentiation of diverse non-proliferating precursors (red) with currently unknown identity to neurons. **b** Neuronal EPO binds in an auto/paracrine manner to EPOR on pyramidal neurons (blue), leading to an increase in dendritic spines. EPO simultaneously binds to EPOR on likely diverse neighboring cells (red), ready to differentiate into neurons on demand. Together, these integrative steps may explain the consistently found improvement of cognitive function under rhEPO treatment and, even more importantly, delineate physiological mechanisms, accomplishing lasting adaptation to challenge via the brain EPO system.

Dendritic spine quantification using the Golgi–Cox method: Images were acquired using the Nikon Ti2 using a 100× objective (NA = 1.45). Stretches of mid-apical dendrites in CA1 pyramidal neurons were recorded with a z-stack size of 0.3 μm. Per animal, ten dendrites of ten different cells were quantified for the number of spines (calculated as spines per μm dendrite).

**Drop sequencing.** In vitro dissociation: Juvenile male WT mice (P28; three mice/group) were injected i.p. with placebo or EPO and sacrificed 30 min later. The hippocampi were dissected into 600 μm thick sections using Mcllwain Tissue chopper (Cavey Laboratory Engineering Co. Ltd). The CA1 region was digested with a working solution of Papain/DNase in Earle’s Balanced Salt Solution, according to manufacturer’s instructions (Worthington Biochemical Corp.). The samples were then incubated at 37 °C for 40 min with constant agitation before gentle manual trituration. The samples were centrifuged for 10 min at 200 × g at 4 °C. After discarding the Papain/DNase supernatant, cells were resuspended in 1 mL of sterile DMEM/F12 (Sigma) without phenol-red containing 3% fetal bovine serum (FBS; Life Technologies) and the suspension was passed through a 40 μm strainer cap (Corning) to yield a uniform single-cell suspension.

Single-cell barcoding and library preparation: Barcoded single cells, or STAMPs (single-cell transcriptomes attached to microparticles), and cDNA libraries were generated following the protocol39. Briefly, single-cell suspensions (100 cells/μl), droplet generation oil (Bio-Rad), and barcoded microparticles (ChemGenes; 120 beads/μl) were co-flowed through a FlowEM aquapel-treated DropSeq microweaver generated for 15 min. Captured RNA on the bead surface was recovered by washing the beads in saline-sodium citrate buffer and perfluorocetanol solutions, and then reverse transcribed using Maxima H minus reverse transcriptase kit (ThermoFisher). Excess primer on the surface of the bead uncaptured by an RNA molecule was digested using Exonuclease I kit (ThermoFisher). A cDNA amplification PCR was performed using 10 μM SMART PCR primer and 2X Kapa HiFi HotStart ReadyMix (Kapa Biosystems) with 5000 beads per tube, and amplified for nine PCR cycles. The resulting samples were purified using AMPureXP beads (Beckman Coulter) and the quality and concentration of the cDNA was assessed using High-sensitivity DNA Bioanalyzer chip (Agilent Technologies). Library sizes were adjusted using the Nextera Balloon Tagmentation enzyme and DNA was amplified for 14 cycles using 10 μM New-P5 SMART PCR hybrid oligo, 10 μM Nextera Index, and the Nextera PCR mix (Nextera XT DNA Library Preparation kit; Illumina). Tagmented libraries were again purified (AMPureXP, quality controlled (high-sensitivity DNA Bioanalyzer), quantified (Qubit DNA HS assay kit; Life Technologies), and sequenced (Illumina Hi-seq 2500). All assays mentioned above have been performed according to manufacturer’s protocol.
Clustering, visualization, and differential expression: Clustering was performed using “FindClusters” function with default parameters with resolution set to 1 and first 20 CCA aligned dimensions were used in the construction of the shared-nearest-neighbor graph and to generate two-dimensional embeddings for data visualization using tSNE. Based on the visualization the glutamatergic cluster 0 and 1 were merged manually to represent a single cluster. The percentages of ‘immature glutamatergic cells’ for each mouse were: placebo 1.6%, 2.3%, and 4.3%; EPO 3.7%, 6.8%, and 7.0%. We used the ‘FindAllMarkers’ function with default parameters and tested genes with a detected threshold of minimum of 25% of cells in either of the two clusters. Genes with an adjusted p < 0.01 were considered to be differentially expressed (for a list of cluster markers see Source Data File). A heatmap showing the top ten marker genes, i.e., differentially expressed genes per cluster is provided in the Supplementary Fig. 2.

Cell trajectory (pseudo-time) analysis: Trajectory analysis of cells from the ‘Immature Glutamatergic’ and ‘Mature Glutamatergic’ clusters (n = 502) was performed in Monocle2. The trajectory was constructed according to the documentation of Monocle2. Prior to cell ordering, reclustering was performed to confirm robust detection of the immature cluster across methods, which revealed three clusters (one cluster largely corresponding to Seurat’s ‘Immature Glutamatergic’ cluster and two corresponding to Seurat’s ‘Mature Glutamatergic’ cluster; Supplementary Fig. 3a). Subsequently, dimension reduction using the ‘DDRTree’ method was performed. Differentially expressed genes (q < 0.01) between the three clusters obtained by reclustering in Monocle2 were used as input for pseudotime ordering.

Quantification and statistical analysis: All statistical analysis was performed using GraphPad Prism 5. For comparisons across multiple groups, a two-way analysis of variance (ANOVA) was used. For comparisons across two groups, an unpaired Student’s t-test was performed. A p < 0.05 is considered statistically significant. Variance was similar between compared groups for their respective experiments. All values represent mean ± SEM (standard error of the mean). All analysis and quantification were performed in a double-blinded fashion.
