Abstract  We derive analytical solutions for the uniaxial extension problem for the relaxed micromorphic continuum and other generalized continua. These solutions may help in the identification of material parameters of generalized continua which are able to disclose size effects.

Keywords  Generalized continua · Uniaxial extension · Uniaxial extension stiffness · Characteristic length · Size effect · Micromorphic continuum · Cosserat continuum · Couple stress model · Gradient elasticity · Micropolar · Relaxed micromorphic model · Micro-stretch model · Micro-strain model · Micro-void model · Bounded stiffness

1 Introduction

In this paper we continue our investigation of analytical solutions for the isotropic relaxed micromorphic model (and other isotropic generalized continuum models). It follows our recent exposition of analytical solutions for the simple shear [28], bending [25], and torsion problem [13, 27]. Here, we consider the uniaxial extension problem, which, in classical isotropic linear elasticity, allows to determine the size-independent longitudinal modulus $M_{\text{macro}} = \lambda_{\text{macro}} + 2\mu_{\text{macro}}$.

Here, we show the genealogy tree of the generalized continuum models:
In the case with arbitrary \( \nu \in \mathbb{R} \), we refer the reader to the introduction of [25, 27, 28, 32] concerning the inhomogeneous response is triggered by the boundary conditions for the additional kinematic fields which are coupling conditions as well greater than the classical linear elasticity. The solution is homogeneous and uniquely determines the longitudinal modulus \( M_{\text{macro}} = \lambda_{\text{macro}} + 2\mu_{\text{macro}} \). Then, we consider the isotropic relaxed micromorphic continuum. The boundary conditions for the additional nonsymmetric micro-distortion field \( P \) derive from the so-called consistent coupling conditions

\[
Du(x) \times \nu = P(x) \times \nu, \quad x \in \Gamma,
\]

where \( \nu \) is the normal unit vector to the upper and lower surface. It turns out that for zero Poisson modulus on the micro- and meso-scale, \( \nu_{\text{micro}} = \nu_{e} = 0 \), respectively, the solution remains homogeneous and no size effects are observed. In the case with arbitrary \( \nu_{\text{micro}}, \nu_{e} \in [-1, 1/2] \) the solution will be inhomogeneous and size effects appear. The limiting stiffness as the ratio between the thickness and the characteristic length tends to zero \( (h/L_{e} \to 0) \) is given by \( M = \frac{M_{e} M_{\text{macro}}}{M_{e} + M_{\text{macro}}} \), which is both smaller than \( M_{\text{micro}} = \lambda_{\text{micro}} + 2\mu_{\text{micro}} \) and \( M_{e} \) as well greater than \( M_{\text{macro}} = \lambda_{\text{macro}} + 2\mu_{\text{macro}} \).
1.1 Notation

We define the scalar product $\langle a, b \rangle := \sum_{i=1}^{n} a_i b_i \in \mathbb{R}$ for vectors $a, b \in \mathbb{R}^n$, the dyadic product $a \otimes b := (a_i b_j)_{i,j=1,...,n} \in \mathbb{R}^{n \times n}$ and the Euclidean norm $\|a\|^2 := \langle a, a \rangle$. We define the scalar product $\langle P, Q \rangle := \sum_{i,j=1}^{n} P_{ij} Q_{ij} \in \mathbb{R}$ and the Frobenius-norm $\|P\|^2 := \langle P, P \rangle$ for tensors $P, Q \in \mathbb{R}^{n \times n}$ in the same way. Moreover, $P^T := (P_{ij})_{i,j=1,...,n}$ denotes the transposition of the matrix $P = (P_{ij})_{i,j=1,...,n}$, which decomposes orthogonally into the skew-symmetric part skew $P := \frac{1}{2}(P - P^T)$ and the symmetric part sym $P := \frac{1}{2}(P + P^T)$. The identity matrix is denoted by $\mathbb{I}$, so that the trace of a matrix $P$ is given by tr $P := \langle P, 1 \rangle$, 1, while the deviatoric component of a matrix is given by dev $P := P - \frac{\text{tr}(P)}{3} \mathbb{I}$. Given this, the orthogonal decomposition possible for a matrix is $P = \text{dev sym} P + \text{skew} P + \frac{\text{tr}(P)}{3} \mathbb{I}$. The Lie-algebra of skew-symmetric matrices is denoted by $\mathfrak{so}(3) := \{ A \in \mathbb{R}^{3 \times 3} \mid A^T = -A \}$, while the vector space of symmetric matrices $\text{Sym}(3) := \{ S \in \mathbb{R}^{3 \times 3} \mid S^T = S \}$. The Jacobian matrix $Du$ and the curl for a vector field $u$ are defined as

$$Du = \begin{pmatrix} u_{1,1} & u_{1,2} & u_{1,3} \\ u_{2,1} & u_{2,2} & u_{2,3} \\ u_{3,1} & u_{3,2} & u_{3,3} \end{pmatrix}, \quad \text{curl } u = \nabla \times u = \begin{pmatrix} u_{3,2} - u_{2,3} \\ u_{1,3} - u_{3,1} \\ u_{2,1} - u_{1,2} \end{pmatrix}. \tag{2}$$

where $\times$ denotes the cross-product in $\mathbb{R}^3$. We also introduce the Curl and the Div operators of the $3 \times 3$ matrix field $P$ as

$$\text{Curl } P = \begin{pmatrix} (\text{curl } (P_{11}, P_{12}, P_{13})^T)^T \\ (\text{curl } (P_{21}, P_{22}, P_{23})^T)^T \\ (\text{curl } (P_{31}, P_{32}, P_{33})^T)^T \end{pmatrix}, \quad \text{Div } P = \begin{pmatrix} \text{div } (P_{11}, P_{12}, P_{13})^T \\ \text{div } (P_{21}, P_{22}, P_{23})^T \\ \text{div } (P_{31}, P_{32}, P_{33})^T \end{pmatrix}. \tag{3}$$

The cross-product between a second-order tensor and a vector is also needed and is defined row-wise as follows

$$m \times b = \begin{pmatrix} (b \times (m_{11}, m_{12}, m_{13})^T)^T \\ (b \times (m_{21}, m_{22}, m_{23})^T)^T \\ (b \times (m_{31}, m_{32}, m_{33})^T)^T \end{pmatrix} = m \cdot b = m_{ij} \epsilon_{ijk} b_k, \tag{4}$$

where $m \in \mathbb{R}^{3 \times 3}$, $b \in \mathbb{R}^3$, and $\boldsymbol{\epsilon}$ is the Levi-Civita tensor. Using the one-to-one map axl : $\mathfrak{so}(3) \rightarrow \mathbb{R}^3$ we have

$$A b = \text{axl}(A) \times b \quad \forall A \in \mathfrak{so}(3), \quad b \in \mathbb{R}^3. \tag{5}$$

The inverse of axl is denoted by Anti: $\mathbb{R}^3 \rightarrow \mathfrak{so}(3)$.

2 Uniaxial extension problem for the isotropic Cauchy continuum

The strain energy density for an isotropic Cauchy continuum is

$$W(Du) = \mu_{\text{macro}} \|\text{sym}Du\|^2 + \frac{\lambda_{\text{macro}}}{2} \text{tr}^2(Du), \tag{6}$$

while the equilibrium equations without body forces are

$$\text{Div} \left[ 2 \mu_{\text{macro}} \text{sym}Du + \lambda_{\text{macro}} \text{tr}(Du) \mathbb{I} \right] = 0. \tag{7}$$

Since the uniaxial extensional problem is symmetric with respect to the $x_2$-axis, there will be no dependence of the solution on $x_1$ and $x_3$. The boundary conditions for the uniaxial extension problem are (see Fig. 1)

$$u_2(x_2 = \pm h/2) = \pm \frac{\gamma h}{2}. \tag{8}$$
The homogeneous displacement field solution \( u_2(x_2) \), the gradient of the displacement \( Du(x_2) \), and the strain energy \( W(\gamma) \) for the uniaxial extension problem are

\[
u_2(x_2) = \gamma x_2, \quad Du(x_2) = \begin{pmatrix} 0 & 0 & 0 \\ 0 & \gamma & 0 \\ 0 & 0 & 0 \end{pmatrix},
\]

\[
W(\gamma) = \int_{-h/2}^{h/2} W(Du) = \frac{1}{2} \left( \lambda_{\text{macro}} + 2 \mu_{\text{macro}} \right) h \gamma^2 = \frac{1}{2} M_{\text{macro}} h \gamma^2.
\]

where

\[
M_{\text{macro}} = \lambda_{\text{macro}} + 2 \mu_{\text{macro}}
\]

is the extensional stiffness (or pressure-wave modulus, longitudinal modulus).

Here and in the remainder of this work, the elastic coefficients \( \mu_i, \lambda_i \) are expressed in [MPa], the coefficients \( a_i \) and the intensity of the displacement \( \gamma \) are dimensionless, the characteristic lengths \( L_c \) and the height \( h \) are expressed in meter [m].

### 3 Uniaxial extension problem for the isotropic relaxed micromorphic model

The general expression of the strain energy for the isotropic relaxed micromorphic continuum is

\[
W(Du, P, \text{Curl } P) = \mu_e \| \text{sym } (Du - P) \|^2 + \frac{\lambda_e}{2} \text{tr}^2 (Du - P) + \mu_c \| \text{skew } (Du - P) \|^2
\]

\[
+ \mu_{\text{micro}} \| P \|^2 + \frac{\lambda_{\text{micro}}}{2} \text{tr}^2 (P)
\]

\[
+ \frac{\mu L_c^2}{2} \left( a_1 \| \text{dev sym } \text{Curl } P \|^2 + a_2 \| \text{skew } \text{Curl } P \|^2 + \frac{a_3}{3} \text{tr}^2 (\text{Curl } P) \right),
\]

and the strictly positive definiteness conditions are\(^1\)

\[
\mu_e > 0, \quad \kappa_e = \lambda_e + 2/3 \mu_e > 0, \quad \mu_{\text{micro}} > 0, \quad \kappa_{\text{micro}} = \lambda_{\text{micro}} + 2/3 \mu_{\text{micro}} > 0,
\]

\[
\mu_c > 0, \quad \kappa_c = \lambda_c + 2/3 \mu_c > 0, \quad \mu_{\text{micro}} > 0, \quad \kappa_{\text{micro}} = \lambda_{\text{micro}} + 2/3 \mu_{\text{micro}} > 0,
\]

where we have the parameters related to the meso-scale, the parameters related to the micro-scale, the Cosserat couple modulus, the proportionality stiffness parameter, the characteristic length and the three dimensionless general isotropic curvature parameters, respectively. This energy expression represents the most general isotropic form possible for the relaxed micromorphic model. In the absence of body forces, the equilibrium equations are then

\[
\begin{align*}
\text{Div} \left[ 2 \mu_e \text{sym } (Du - P) + \lambda_e \text{tr} (Du - P) \right] + 2 \mu_c \text{skew } (Du - P) &= 0, \\
\tilde{\sigma} - 2 \mu_{\text{micro}} \text{sym } P - \lambda_{\text{micro}} \text{tr } (P) &= 0 \quad \text{for } \tilde{\sigma} = \mu L_c^2 \text{Curl} (a_1 \| \text{dev sym } \text{Curl } P + a_2 \| \text{skew } \text{Curl } P + a_3 \| \text{tr} (\text{Curl } P)),
\end{align*}
\]

The ansatz for the micro-distortion \( P(x_2) \), the displacement \( u(x_2) \), and consequently the gradient of the displacement \( Du(x_2) \) is

\[
u(x_2) = \begin{pmatrix} u_2(x_2) \\ 0 \end{pmatrix}, \quad P(x_2) = \begin{pmatrix} P_{11}(x_2) & 0 & 0 \\ 0 & P_{22}(x_2) & 0 \\ 0 & 0 & P_{33}(x_2) \end{pmatrix},
\]

\[
Du(x_2) = \begin{pmatrix} 0 & 0 & 0 \\ 0 & u_{2,2}(x_2) & 0 \\ 0 & 0 & 0 \end{pmatrix}.
\]

\(^1\) Note that the model has a unique solution including the case of a Cosserat couple modulus \( \mu_c = 0 \).
It is important to underline that, given subsequent ansatz (14), it holds that \( \text{tr} (\text{Curl } P) = 0 \). This reduces immediately the number of curvature parameters appearing in the uniaxial extension solution.

The boundary conditions for the uniaxial extension are

\[
\begin{align*}
   u_2(x_2 = \pm h/2) &= \pm \frac{\gamma h}{2} , \\
   P_{11}(x_2 = \pm h/2) &= 0 , \\
   P_{33}(x_2 = \pm h/2) &= 0 .
\end{align*}
\]

Here, the constraint on the components of \( P \) is given by the consistent coupling boundary condition

\[
P \times v = Du \times v ,
\]

where \( v \) is the normal unit vector to the upper and lower surface.

After substituting ansatz (14) into equilibrium equation (13) we obtain the following four differential equations

\[
M_e \left( u_{2}''(x_2) - P_{22}''(x_2) \right) - \lambda_e \left( P_{11}'(x_2) + P_{33}'(x_2) \right) = 0 ,
\]

\[
\frac{1}{2} \mu L_c^2 \left( (a_1 + a_2) P_{11}''(x_2) + (a_2 - a_1) P_{33}''(x_2) \right)
\]

\[
-(M_e + M_{micro}) P_{11}(x_2) - (\lambda_e + \lambda_{micro})(P_{22}(x_2) + P_{33}(x_2)) + \lambda_e u_{2}'(x_2) = 0 ,
\]

\[
-(M_e + M_{micro}) P_{22}(x_2) + M_e u_{2}'(x_2) - (\lambda_e + \lambda_{micro})(P_{11}(x_2) + P_{33}(x_2)) = 0 ,
\]

\[
\frac{1}{2} \mu L_c^2 \left( (a_2 - a_1) P_{11}''(x_2) + (a_1 + a_2) P_{33}''(x_2) \right)
\]

\[
-(M_e + M_{micro}) P_{33}(x_2) - (\lambda_e + \lambda_{micro})(P_{11}(x_2) + P_{22}(x_2)) + \lambda_e u_{2}'(x_2) = 0 ,
\]

where \( M_e = \lambda_e + 2 \mu_e \) and \( M_{micro} = \lambda_{micro} + 2 \mu_{micro} \). Being careful of substituting the system of differential equation with one in which Eq. (17)\(_2\) and Eq. (17)\(_4\) are replaced with their sum and their difference, respectively, we have

\[
M_e \left( u_{2}''(x_2) - P_{22}''(x_2) \right) - \lambda_e f_p'(x_2) = 0 ,
\]

\[
a_2 \mu L_c^2 f_p''(x_2) - (M_e + \lambda_e + M_{micro} + \lambda_{micro}) f_p(x_2) - 2(\lambda_e + \lambda_{micro}) P_{22}(x_2) + 2 \lambda_e u_{2}'(x_2) = 0 ,
\]

\[
-(M_e + M_{micro}) P_{22}(x_2) + M_e u_{2}'(x_2) - (\lambda_e + \lambda_{micro}) f_p(x_2) = 0 ,
\]

\[
a_1 \mu L_c^2 f_m''(x_2) - (M_{micro} + M_e - \lambda_e - \lambda_{micro}) f_m(x_2) = 0 ,
\]

where \( f_p(x_2) := P_{11}(x_2) + P_{33}(x_2) \) and \( f_m(x_2) := P_{11}(x_2) - P_{33}(x_2) \). It is highlighted that Eq. (18)\(_4\) is a homogeneous second-order differential equation depending only on \( f_m(x_2) \) with homogeneous boundary conditions Eq. (15).

The fact that Eq. (18)\(_4\) is an independent equation has its meaning in the symmetry constraint of the uniaxial extensional problem in the direction along the \( x_2 \)- and \( x_3 \)-axis, which requires that \( P_{11}(x_2) = P_{33}(x_2) \). From Eq. (18) it is possible to obtain the following relation between \( P_{22}(x_2) \) and \( u_2(x_2) \)

\[
P_{22}(x_2) = \frac{M_e u_{2}'(x_2) - (\lambda_e + \lambda_{micro}) f_p(x_2)}{M_e + M_{micro}} ,
\]

which, after substituting it back into Eq. (18), allows us to obtain the following system of three second-order differential equations in \( u_2(x_2), P_{22}(x_2), \) and \( f_p(x_2) \)

\[
z_1 f_p'(x_2) + z_2 u_{2}'(x_2) = 0 ,
\]

\[
a_2 \mu L_c^2 f_p''(x_2) - z_3 f_p(x_2) - 2z_1 u_{2}'(x_2) = 0 ,
\]

\[
a_1 \mu L_c^2 f_m''(x_2) - (M_e + M_{micro} - \lambda_e - \lambda_{micro}) f_m(x_2) = 0 ,
\]
where

\[
\begin{align*}
\zeta_1 &= \frac{M_0 \lambda_{\text{micro}} - \lambda_e M_{\text{micro}}}{M_e + M_{\text{micro}}}, \\
\zeta_2 &= \frac{M_e M_{\text{micro}}}{M_e + M_{\text{micro}}}, \\
\zeta_3 &= \frac{(M_e - \lambda_e + M_{\text{micro}} - \lambda_{\text{micro}})}{M_e + M_{\text{micro}}}. \\
\end{align*}
\]

(21)

It is highlighted that due to positive definiteness conditions (12), \((\zeta_2, \zeta_3) > 0\) and \(\zeta_1 = 0\) if and only if \(\lambda_{\text{micro}} = \lambda_e = 0\) (zero Poisson’s ratio case which is studied in Sect. 3.1) and \(\frac{M_{\text{micro}}}{M_e} = \frac{\kappa_{\text{micro}}}{\kappa_e}\). If \(\zeta_1\) is zero, Eq. (20) uncouples completely into three independent differential equations in \(u_2\), \(P_{11}\), and \(P_{33}\), respectively.

After applying boundary conditions Eq. (15), the solution in terms of \(u_2(x_2)\), \(P_{11}(x_2)\), \(P_{22}(x_2)\), and \(P_{33}(x_2)\) of system Eq. (20) is

\[
\begin{align*}
u_2(x_2) &= \frac{2z_2 - \frac{4z_1^2}{f_1 z_2}}{1 - \frac{4z_1^2}{f_1 z_2}} \frac{\text{sech} \left( \frac{f_1 h}{2z_2} \right) \sinh \left( \frac{f_1 x_2}{L_e} \right)}{L_e} y h, \\
P_{22}(x_2) &= \frac{M_e + M_{\text{micro}}}{M_e + M_{\text{micro}}} \left( 1 - \frac{4z_1^2}{f_1 z_2} \frac{\tanh \left( \frac{f_1 h}{2z_2} \right)}{L_e} \right) y, \\
P_{11}(x_2) &= \frac{z_1}{z_2} \frac{\text{sech} \left( \frac{f_1 h}{2z_2} \right) \cosh \left( \frac{f_1 x_2}{L_e} \right) - 1}{1 - \frac{4z_1^2}{f_1 z_2} \frac{\tanh \left( \frac{f_1 h}{2z_2} \right)}{L_e}} y, \\
f_1 &= \frac{2z_2 - 2z_1^2}{\mu a_2 z_2}. \\
\end{align*}
\]

(22)

In the above expressions all the quantities are real and well defined due to positive definiteness conditions Eq. (12). Indeed, since the coefficients \(z_1, z_2,\) and \(z_3\) may be rewritten in terms of the meso- and micro-bulk and shear modulus as

\[
\begin{align*}
z_1 &= \frac{6\kappa_{\text{micro}}\mu_e - 6\kappa_e \mu_{\text{micro}}}{3\kappa_e + 3\kappa_{\text{micro}} + 4(\mu_e + \mu_{\text{micro}})}, \\
z_2 &= \frac{(3\kappa_e + 4\mu_e)(3\kappa_{\text{micro}} + 4\mu_{\text{micro}})}{9\kappa_e + 9\kappa_{\text{micro}} + 12(\mu_e + \mu_{\text{micro}})}, \\
z_3 &= \frac{18(\kappa_e + \kappa_{\text{micro}})(\mu_e + \mu_{\text{micro}})}{3\kappa_e + 3\kappa_{\text{micro}} + 4(\mu_e + \mu_{\text{micro}})}. \\
\end{align*}
\]

we can write the expression of \(f_1\) as follows

\[
f_1 = \sqrt{\frac{6\kappa_{\text{micro}} \mu_e + \mu_{\text{micro}}(\mu_e + \mu_{\text{micro}}) + 8\mu_e \kappa_{\text{micro}} (\kappa_e + \kappa_{\text{micro}})}{\mu a_2 (\kappa_e + \frac{2\kappa_{\text{micro}}}{3})(\kappa_{\text{micro}} + \frac{4\mu_{\text{micro}}}{3})}},
\]

(23)

showing that the positive definiteness of energy (11) implies that \(f_1\) is a strictly positive real number. Moreover, the function \(g : (0, \infty) \to \mathbb{R}, \ g(x) := 1 - \frac{4z_1^2}{z_2 z_3} \frac{1}{x} \tanh \frac{x}{2}\) has the asymptotic behavior

\[
\lim_{x \to 0^+} g(x) = 1 - \frac{2z_1^2}{z_2 z_3} = f_1^2 > 0, \quad \lim_{x \to \infty} g(x) = 1
\]

(24)

and it is monotone increasing since its first derivative is given by

\[
g'(x) = \frac{4z_1^2}{z_2 z_3} \frac{\sinh x - x}{x (\cosh x + 1)}
\]

(25)

which it is positive for all \(x \in (0, \infty)\). Hence, it follows that due to the positive definiteness of the elastic energy

\[
g(x) > 0 \quad \forall x > 0,
\]

(26)

\(^2\text{sech}(x) = 1/cosh(x).\)
which implies that

\[ 1 - \frac{4c_i^2}{f_1}\frac{1}{2}\frac{f_1 h}{L_c} \tanh \left( \frac{f_1 h}{2L_c} \right) \frac{L_c}{h} > 0 \quad \forall \ L_c > 0 \]  

which completes our proof that all the quantities from (22) are real and well-defined.

The strain energy associated with this solution is

\[
W(\gamma) = \int_{-h/2}^{h/2} W(\mathbf{Du}, \mathbf{P}, \text{Curl} \mathbf{P})
\]

\[
= \frac{1}{2} \left[ \frac{\mu a_2 (f_{1z}^2)}{f_{1z}^2} \left( \frac{1}{f_1} \sinh \left( \frac{f_1 h}{L_c} \right) \frac{L_c}{h} - 1 \right) \right. \\
\left. + \cosh^2 \left( \frac{f_1 h}{2L_c} \right) - \frac{c_i^2}{z^2} \sinh^2 \left( \frac{f_1 h}{L_c} \right) \frac{L_c}{h} - 1 \right] \\
\times \frac{2}{z^2} \left[ M_e + M_{\text{micro}} + \lambda_e + \lambda_{\text{micro}} - \frac{2\lambda_e}{M_e} - \frac{2\lambda_{\text{micro}}}{M_{\text{micro}}} \right] h \gamma^2 = \frac{1}{2} M_w \ h \gamma^2. 
\]

The plot of the extensional stiffness \( M_w \) while varying \( L_c \) is shown in Fig. 2.

The values of \( M_{\text{macro}} \) and \( M_{\text{micro}} \) are

\[
M_{\text{macro}} = \lim_{L_c \to 0} M_w = \frac{M_e^2 M_{\text{micro}} + M_e (\lambda_e + \lambda_{\text{micro}}) - 2\lambda_e^2 M_{\text{micro}}}{M_e M_{\text{micro}}} \\
= \frac{\kappa_{\text{micro}}}{\lambda_{\text{micro}}} + \frac{4}{3} \frac{\mu_e}{\mu_{\text{micro}}} = \kappa_{\text{macro}} + \frac{4}{3} \mu_{\text{macro}} = M_{\text{macro}},
\]

\[
M_{\text{micro}} = \lim_{L_c \to \infty} M_w = \frac{M_e M_{\text{micro}}}{M_e + M_{\text{micro}}},
\]

where \( M_i = \kappa_i + \frac{4}{3} \mu_i \) and \( \lambda_i = \kappa_i - \frac{2}{3} \mu_i \) with \( i = \{\text{macro}, \text{micro}, \text{e}\} \).

It is highlighted that the structure \((\bullet)_{\text{e}} + (\bullet)_{\text{micro}}\) is applicable to evaluate the \textit{macro} coefficients only for the shear and bulk modulus because of the orthogonal energy decomposition “sym dev/tr” of which they are related, and especially here it would be a mistake to use this structure for the coefficient \( M_{\text{macro}} \) since it will give the value at the \textit{micro}-scale. For more details about \( \lim_{L_c \to \infty} M_w \) see Appendix A.

---

3 For the sake of completeness are reported here also the relations between the Young’s modulus \( E_i \) and the Poisson’s ratio \( \nu_i \) in terms of \( \kappa_i \) and \( \mu_i \): \( E_i = \frac{\kappa_i}{\lambda_i + \mu_i} \) and \( \nu_i = \frac{\kappa_i - 2\mu_i}{2(\lambda_i + \mu_i)} \) with \( i = \{\text{macro}, \text{micro}, \text{e}\} \).
3.1 Uniaxial extension problem for the isotropic relaxed micromorphic model with $\nu_e = \nu_{\text{micro}} = 0$

A vanishing Poisson’s ratio at the meso- and micro-scale ($\nu_e = \nu_{\text{micro}} = 0$) corresponds to a vanishing first Lamé parameter ($\lambda_e = \lambda_{\text{micro}} = 0$). It is easy to see from Eqs. (21) and (22) that these conditions correspond to

$$\lambda_e = \lambda_{\text{micro}} = 0 \iff \begin{cases} z_1 = 0, \\ z_2 = \frac{M_e}{M_e + M_{\text{micro}}} = \frac{2\mu_e}{\mu_e + \mu_{\text{micro}}}, \\ z_3 = M_e + M_{\text{micro}} = 2(\mu_e + \mu_{\text{micro}}), \end{cases} \quad (30)$$

with $M_i = \lambda_i + 2\mu_i = 2\mu_i$ with $i \in \{\text{micro, e}\}$. Since the nonlinear terms in solution Eq. (22) vanish, we retrieve

$$u_2(x_2) = \gamma x_2, \quad P_{22}(x_2) = \frac{\mu_e}{\mu_e + \mu_{\text{micro}}} \gamma, \quad P_{11}(x_2) = P_{33}(x_2) = 0, \quad (31)$$

which is a homogeneous elastic solution satisfying the equilibrium equation in the case of a constant micro-distortion tensor $\bar{P}$ (see Appendix D of [27] for further details)

$$\bar{P} = \frac{\mu_e}{\mu_e + \mu_{\text{micro}}} \left( \frac{1}{|\Omega|} \int_\Omega \text{D} u \, dV \right). \quad (32)$$

The strain energy associated with this solution is

$$W(\gamma) = \int_{-h/2}^{h/2} W(\text{D} u) = \frac{1}{2} \frac{2\mu_e}{\mu_e + \mu_{\text{micro}}} h \gamma^2 = \frac{1}{2} M_{\text{macro}} h \gamma^2, \quad (33)$$

where $M_{\text{macro}} = 2\mu_{\text{macro}} + \lambda_{\text{macro}} = 2\mu_{\text{macro}} = \frac{2\mu_e \mu_{\text{macro}}}{\mu_e + \mu_{\text{micro}}}$ is the macro-extensional stiffness, since $\lambda_{\text{macro}} = \nu_{\text{macro}} = 0$.

4 Uniaxial extension problem for the isotropic micro-stretch model in dislocation format

In the micro-stretch model in dislocation format [5, 15, 20, 22, 30], the micro-distortion tensor $P$ is devoid from the deviatoric component $\text{dev sym} \, P = 0 \iff P = A + \omega \mathbb{1}$, $A \in \mathfrak{so}(3)$, $\omega \in \mathbb{R}$. The expression of the strain energy for this model in dislocation format can be written as [20]:

$$W(\text{D} u, A, \omega, \text{Curl} \, (A - \omega \mathbb{1})) = \mu_{\text{macro}} \|\text{dev sym} \, \text{D} u\|^2 + \frac{\kappa_e}{2} \text{tr}^2 (\text{D} u - \omega \mathbb{1}) + \mu_e \|\text{skew} \, (\text{D} u - A)\|^2 + \frac{9}{2} \kappa_{\text{macro}} \omega^2$$

$$+ \frac{\mu L_c^2}{2} \left( a_1 \|\text{dev sym} \, \text{Curl} \, A\|^2 + a_2 \|\text{skew} \, \text{Curl} \, (A + \omega \mathbb{1})\|^2 + \frac{a_3}{3} \text{tr}^2 (\text{Curl} \, A) \right), \quad (34)$$

since $\text{Curl} \, (\omega \mathbb{1}) \in \mathfrak{so}(3)$. The equilibrium equations, in the absence of body forces, are then

$$\text{Div} \left[ 2\mu_{\text{macro}} \text{dev sym} \, \text{D} u + \kappa_e \text{tr} \, (\text{D} u - \omega \mathbb{1}) + 2\mu_e \text{skew} \, (\text{D} u - A) \right] = 0,$$

$$2\mu_e \text{skew} \, (\text{D} u - A)$$

$$- \mu L_c^2 \text{skew} \, \text{Curl} \left( a_1 \text{dev sym} \, \text{Curl} \, A + a_2 \text{skew} \, \text{Curl} \, (A + \omega \mathbb{1}) + \frac{a_3}{3} \text{tr} \, (\text{Curl} \, A) \mathbb{1} \right) = 0,$$

$$\text{tr} \left[ 2\mu_{\text{macro}} \text{dev sym} \, \text{D} u$$

$$+ \kappa_e \text{tr} \, (\text{D} u - \omega \mathbb{1}) \mathbb{1} - \kappa_{\text{micro}} \text{tr} \, (\omega \mathbb{1}) \mathbb{1} - \mu L_c^2 a_2 \text{Curl} \, \text{skew} \, (\omega \mathbb{1} + A) \right] = 0. \quad (35)$$
According to the reference system shown in Fig. 1, the ansatz for the displacement and micro-distortion fields is

\[
\begin{align*}
    u(x_2) &= \begin{pmatrix} 0 \\ u_2(x_2) \\ 0 \end{pmatrix}, &
    A(x_2) &= \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}, \\
    D u(x_2) &= \begin{pmatrix} 0 & 0 & 0 \\ 0 & u_2,2(x_2) & 0 \\ 0 & 0 & 0 \end{pmatrix}, &
    \omega(x_2) 1 &= \begin{pmatrix} \omega(x_2) & 0 & 0 \\ 0 & \omega(x_2) & 0 \\ 0 & 0 & \omega(x_2) \end{pmatrix}.
\end{align*}
\] (36)

The boundary conditions at the free surface are then

\[
\begin{align*}
    u_2(x_2 = \pm h/2) &= \pm \gamma h/2, &
    \omega(x_2 = \pm h/2) &= 0.
\end{align*}
\] (37)

Since the ansatz requires \( A = 0 \), the micro-stretch model coincides with the micro-void model which will be presented in Sect. 6.

### 5 Uniaxial extension problem for the isotropic Cosserat continuum

The strain energy for the isotropic Cosserat continuum in dislocation tensor format (curvature energy expressed in terms of \( \text{Curl} A \)) can be written as \([3,8,13,14,18,21,25,28,29]\)

\[
W(Du, A, \text{Curl} A) = \mu_{\text{macro}} \| \text{sym} Du \|^2 + \frac{\lambda_{\text{macro}}}{2} \text{tr}^2(Du) + \mu_{c} \| \text{skew}(Du - A) \|^2 + \frac{\mu L_c^2}{2} \left( a_1 \| \text{dev} \text{sym} \text{Curl} A \|^2 + a_2 \| \text{skew} \text{Curl} A \|^2 + \frac{a_3}{3} \text{tr}^2(\text{Curl} A) \right),
\] (38)

where \( A \in \mathfrak{so}(3) \). The equilibrium equations, in the absence of body forces, are therefore the following

\[
\begin{align*}
    \text{Div} \left[ 2\mu_{\text{macro}} \text{sym} Du + \lambda_{\text{macro}} \text{tr} (Du) 1 + 2\mu_{c} \text{skew} (Du - A) \right] &= 0, \\
    2\mu_{c} \text{skew} (Du - A) - \mu L_c^2 \text{skew} \text{Curl} \left( a_1 \text{dev} \text{sym} \text{Curl} A + \frac{a_3}{3} \text{tr} (\text{Curl} A) 1 \right) &= 0.
\end{align*}
\] (39)

According to the reference system shown in Fig. 1 and ansatz (14), which has to be particularized as \( A = \text{skew} P \in \mathfrak{so}(3) \), the ansatz for the displacement field and the micro-rotation for the Cosserat model is

\[
\begin{align*}
    u(x_2) &= \begin{pmatrix} 0 \\ u_2(x_2) \\ 0 \end{pmatrix}, &
    D u(x_2) &= \begin{pmatrix} 0 & 0 & 0 \\ 0 & u_2,2(x_2) & 0 \\ 0 & 0 & 0 \end{pmatrix}, &
    A(x_2) &= \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}.
\end{align*}
\] (40)

Since \( A = 0 \), the Cosserat model is not able to catch any nonhomogeneous response for the uniaxial extension problem and classical solution (9) is retrieved.

The couple stress model \([10,11,16,19,23]\), which appears by constraining \( A = \text{skew} Du \in \mathfrak{so}(3) \) in the Cosserat model, is also not able to catch a nonhomogeneous response for the uniaxial extension problem since, due to the ansatz, we would have \( \text{skew} Du = 0 \) as it can be seen in Eq. (40).

### 6 Uniaxial extension problem for the isotropic micro-void model in dislocation tensor format

The strain energy for the isotropic micro-void continuum in dislocation tensor format can be obtained from the relaxed micromorphic model by formally letting \( \mu_{\text{micro}} \rightarrow \infty \) (while keeping \( \kappa_{\text{micro}} \) finite) and can be written as \([4,28]\)
\[ W(Du, \omega, \text{Curl} (\omega \mathbb{I})) = \mu_{\text{macro}} \| \text{dev sym} Du \|^2 + \frac{\kappa_e}{2} \text{tr}^2 (Du - \omega 1) + \frac{\kappa_{\text{micro}}}{2} \text{tr}^2 (\omega 1) \\
+ \frac{\mu}{2} \frac{L_c^2}{a_2} \| \text{Curl} (\omega 1) \|^2. \]  

(41)

Here, \( \omega : \mathbb{R}^3 \rightarrow \mathbb{R} \) is the additional scalar micro-void degree of freedom [4]. The equilibrium equations, in the absence of body forces, are

\[ \text{Div} \left[ 2\mu_{\text{macro}} \text{dev sym} Du + \kappa_e \text{tr} (Du - \omega 1) \right] = 0, \]

\[ \frac{1}{3} \text{tr} \left[ \tilde{\sigma} - \kappa_{\text{micro}} \text{tr} (\omega 1) \right] = 0. \]

(42)

and the positive definiteness conditions are

\[ \mu_{\text{macro}} > 0, \quad \kappa_e > 0, \quad \kappa_{\text{micro}} > 0, \quad \mu > 0, \quad L_c > 0, \quad a_2 > 0. \]

(43)

According to the reference system shown in Fig. 1, the ansatz for the displacement field and the function \( \omega(x_2) \) have to be

\[ u(x_1, x_2) = \begin{pmatrix} -x_2 x_3 \\ x_1 x_3 \\ 0 \end{pmatrix}, \quad \omega(x_2) 1 = \begin{pmatrix} \omega(x_2) & 0 & 0 \\ 0 & \omega(x_2) & 0 \\ 0 & 0 & \omega(x_2) \end{pmatrix}, \]

\[ Du(x_2) = \begin{pmatrix} 0 & 0 & 0 \\ 0 & u_{2,2}(x_2) & 0 \\ 0 & 0 & 0 \end{pmatrix}. \]

(44)

The boundary conditions for the uniaxial extension are

\[ u_2(x_2 = \pm h/2) = \pm \frac{\gamma h}{2}, \quad \omega(x_2 = \pm h/2) = 0. \]

(45)

After substituting ansatz (44) into equilibrium equations (42) we obtain the following two differential equations

\[ \frac{2}{3} a_2 \mu L_c^2 \omega''(x_2) + 3 \kappa_e \omega'(x_2) - 3(\kappa_e + \kappa_{\text{micro}}) \omega(x_2) = 0. \]

(46)

After applying boundary conditions Eq. (45), the solution in terms of \( u_2(x_2) \) and \( \omega(x_2) \) of system Eq. (46) is

\[ u_2(x_2) = \frac{x_2 \frac{\sigma}{h} - \frac{1}{2} \sigma \sech \left( \frac{\gamma h}{2L_c} \right) \sinh \left( \frac{\sigma x_3}{L_c} \right)}{1 - \frac{2z_1}{f_1} \tanh \left( \frac{\gamma h}{2L_c} \right) \frac{L_c}{h}} h \gamma, \quad \omega(x_2) = \frac{z_2 \left( 1 - \sech \left( \frac{\gamma h}{2L_c} \right) \cosh \left( \frac{\sigma x_3}{L_c} \right) \right) \gamma}{1 - \frac{2z_1}{f_1} \tanh \left( \frac{\gamma h}{2L_c} \right) \frac{L_c}{h}}, \]

\[ f_1 := \frac{4 \mu_{\text{macro}} (\kappa_e + \kappa_{\text{micro}}) + 3 \kappa_e \kappa_{\text{micro}}}{2 \mu a_2 (3 \kappa_e + 4 \mu_{\text{macro}})}, \quad z_1 := \frac{3 \kappa_e^2}{(\kappa_e + \kappa_{\text{micro}})(3 \kappa_e + 4 \mu_{\text{macro}})}, \quad z_2 := \frac{3 \kappa_e}{3(\kappa_e + \kappa_{\text{micro}})}. \]

(47)

where \( f_1 > 0, \ z_1 > 0, \) and \( z_2 > 0 \) are strictly positive in order to match positive definiteness conditions Eq. (43), and the same reasoning applied in the relaxed micromorphic model sections still holds. The strain energy associated with this solution is

\[ W(\gamma) = \int_{-h/2}^{h/2} W(Du, \omega, \text{Curl} P) \\
= \frac{1}{2} \left[ \frac{\mu a_2 f_1 z_2 \left( \frac{\sigma}{h} \sinh \left( \frac{\gamma h}{2L_c} \right) \frac{L_c}{h} - 1 \right)}{\left( 1 - \frac{2z_1}{f_1} \tanh \left( \frac{\gamma h}{2L_c} \right) \frac{L_c}{h} \right)^2 \cosh^2 \left( \frac{\sigma x_3}{L_c} \right)} + \frac{1 + z_1 + \cosh \left( \frac{\gamma h}{2L_c} \right) - 3 \frac{\sigma}{h} \sinh \left( \frac{\gamma h}{2L_c} \right) \frac{L_c}{h}}{2 \left( 1 - \frac{2z_1}{f_1} \tanh \left( \frac{\gamma h}{2L_c} \right) \frac{L_c}{h} \right)^2 \cosh^2 \left( \frac{\gamma h}{2L_c} \right)} \left( \frac{\kappa_e \kappa_{\text{micro}}}{\kappa_e + \kappa_{\text{micro}}} + \frac{4 \mu_{\text{macro}}}{3} \right) \right] h \gamma^2 \\
= \frac{1}{2} \tilde{W} h \gamma^2. \]

(48)
The expression of the strain energy for the classical isotropic micromorphic continuum \[7, 17\] without mixed terms (like $\mu$ values of the parameters used are: $\mu = 1, \lambda = 1, M_e = 2, \kappa_{\text{micro}} = 3, a_2 = 1/5$.

The plot of the extensional stiffness $M_w$ while varying $L_c$ is shown in Fig. 3. The values of the extensional stiffness $M_w$ for $L_c \to 0$ and $L_c \to \infty$ are

$$
\lim_{L_c \to 0} M_w = \frac{\kappa_e \kappa_{\text{micro}}}{\kappa_e + \kappa_{\text{micro}}} + \frac{4}{3} \mu_{\text{macro}} = \kappa_{\text{macro}} + \frac{4}{3} \mu_{\text{macro}} = 2 \mu_{\text{macro}} + \lambda_{\text{macro}} = M_{\text{macro}},
$$

$$
\lim_{L_c \to \infty} M_w = \kappa_e + \frac{4}{5} \mu_{\text{macro}} = \kappa_e + \frac{4}{3} \mu_e = 2 \mu_e + \lambda_e = M_e,
$$

where $\mu_{\text{macro}} = \mu_e$ for $\mu_{\text{micro}} \to \infty$, according to Eq. (29). We note that the extensional stiffness remains bounded as $L_c \to \infty$ ($h \to 0$).

### 7 Uniaxial extension problem for the classical isotropic micromorphic continuum without mixed terms

The expression of the strain energy for the classical isotropic micromorphic continuum \[7, 17\] without mixed terms (like $(\text{sym} P, \text{sym} (D u - P))$, etc.) and simplified curvature expression \[25, 27\] can be written as:

$$
W(Du, P, DP) = \mu_e \|\text{sym} (Du - P)\|^2 + \frac{\lambda_e}{2} \text{tr}^2 (Du - P) + \mu_e \|\text{skew} (Du - P)\|^2
$$

$$
+ \mu_{\text{micro}} \|\text{sym} P\|^2 + \frac{\lambda_{\text{micro}}}{2} \text{tr}^2 (P)
$$

$$
+ \mu \frac{L_c^2}{2} \left( \tilde{a}_1 \|\text{D (dev sym} P)\|^2 + \tilde{a}_2 \|\text{D (skew} P)\|^2 + \frac{2}{9} \tilde{a}_3 \|\text{D (tr} P)\|\|^2 \right)
$$

while the equilibrium equations without body forces are the following:

$$
\text{Div} \left[ 2 \mu_e \text{sym} (Du - P) + \lambda_e \text{tr} (Du - P) \parallel + 2 \mu_e \text{skew} (Du - P) \right] = 0,
$$

$$
\tilde{\sigma} - 2 \mu_{\text{micro}} \text{sym} P - \lambda_{\text{micro}} \text{tr} (P) \parallel
$$

$$
+ \mu \frac{L_c^2}{2} \text{Div} \left[ \tilde{a}_1 \text{D (dev sym} P) + \tilde{a}_2 \text{D (skew} P) + \frac{2}{9} \tilde{a}_3 \text{D (tr} P) \parallel \right] = 0,
$$

where $(\mu_e, \kappa_e = \lambda_e + 2/3 \mu_e)$, $(\mu_{\text{micro}}, \kappa_{\text{micro}} = \lambda_{\text{micro}} + 2/3 \mu_{\text{micro}})$, $\mu_e, L_c > 0$, and $(\tilde{a}_1, \tilde{a}_2, \tilde{a}_3) > 0$ in order to guarantee the positive definiteness of the energy. According to the reference system shown in Fig. 1, the ansatz for the displacement field and the classical micromorphic model is

$$
u(x_2) = \begin{pmatrix} 0 \\ u_2(x_2) \\ 0 \end{pmatrix}, \quad P(x_2) = \begin{pmatrix} P_{11}(x_2) & 0 & 0 \\ 0 & P_{22}(x_2) & 0 \\ 0 & 0 & P_{33}(x_2) \end{pmatrix},
$$

$$
Du(x_2) = \begin{pmatrix} 0 & 0 \\ 0 & u_{2,2}(x_2) \\ 0 & 0 \end{pmatrix}.
$$

(52)
The boundary conditions for the uniaxial extension are assumed to be

\[ u_2(x_2) = \pm h/2 = \pm \frac{y h}{2}, \quad P(x_2) = 0. \]  (53)

The calculations are deferred to micro-strain model Sect. 8 since the ansatz, the equilibrium equations, and the boundary conditions are the same; therefore, the solution will also be the same.

8 Uniaxial extension problem for the micro-strain model without mixed terms

The micro-strain model [9,12,31] is the classical Mindlin–Eringen [7,17] model particular case in which it is assumed a priori that the micro-distortion remains symmetric, \( P = S \in \text{Sym}(3) \).

The strain energy which we consider is [25,27]

\[
W(Du, S, DS) = \mu_e \| (\text{sym} Du - S) \|^2 + \frac{\lambda_e}{2} \text{tr}^2(Du - S) + \mu_{\text{micro}} \| S \|^2 + \frac{\lambda_{\text{micro}}}{2} u^2(S) \\
\quad + \frac{\mu L^2}{2} \left( \tilde{\alpha}_1 \| D(\text{dev} S) \|^2 + \frac{2}{9} \tilde{\alpha}_3 \| D(\text{tr}(S) 1) \|^2 \right). \]  (54)

The chosen 2-parameter curvature expression represents a simplified isotropic curvature (the full isotropic curvature for the micro-strain model would still count 8 parameters [2]).

The equilibrium equations, in the absence of body forces, are therefore the following

\[
\text{Div} \left[ 2\mu_e (\text{sym} Du - S) + \lambda_e \text{tr}(Du - S) \mathbb{1} \right] = 0, \\
2\mu_e (\text{sym} Du - S) + \lambda_e \text{tr}(Du - S) \mathbb{1} - 2\mu_{\text{micro}} S - \lambda_{\text{micro}} \text{tr}(S) \mathbb{1} \\
\quad + \mu L^2 \text{sym Div} \left[ \tilde{\alpha}_1 D(\text{dev} S) + \frac{2}{9} \tilde{\alpha}_3 D(\text{tr}(S) \mathbb{1}) \right] = 0, \]  (55)

where \((\lambda_e, \mu_e) = (\lambda_e + 2/3 \mu_e)\), \((\mu_{\text{micro}}, \lambda_{\text{micro}}) = (\lambda_{\text{micro}} + 2/3 \mu_{\text{micro}})\), \(L_e > 0\), and \((\tilde{\alpha}_1, \tilde{\alpha}_3) > 0\) in order to guarantee the positive definiteness of the energy. The boundary conditions for the uniaxial extension are assumed to be

\[ u_2(x_2) = \pm h/2 = \pm \frac{y h}{2}, \quad S(x_2) = \pm h/2 = 0. \]  (56)

According to the reference system shown in Fig. 1, the ansatz for the displacement field and the micro-distortion is (which coincides with classical micromorphic model Eq. (52))

\[
u(x_2) = \begin{pmatrix} 0 \\ u_2(x_2) \\ 0 \end{pmatrix}, \quad S(x_2) = \begin{pmatrix} S_{11}(x_2) & 0 & 0 \\ 0 & S_{22}(x_2) & 0 \\ 0 & 0 & S_{33}(x_2) \end{pmatrix},
\]

\[
Du(x_2) = \begin{pmatrix} 0 & 0 & 0 \\ 0 & u_{2,2}(x_2) & 0 \\ 0 & 0 & 0 \end{pmatrix}. \]  (57)

After substituting ansatz (57) into equilibrium equations (55) we obtain the following four differential equations

\[
M_e (u'_2(x_2) - P'_{12}(x_2)) - \lambda_e (P'_{11}(x_2) + P'_{33}(x_2)) = 0, \\
- \frac{2}{9} \mu L^2 (3\tilde{\alpha}_1 + \tilde{\alpha}_3) P'_{11}(x_2) + \frac{1}{9} \mu L^2 (3\tilde{\alpha}_1 - 2\tilde{\alpha}_3) (P'_{22}(x_2) + P'_{33}(x_2)) \\
\quad + (M_e + M_{\text{micro}}) P_{11}(x_2) + (\lambda_e + \lambda_{\text{micro}})(P_{22}(x_2) + P_{33}(x_2)) - \lambda_e u'_2(x_2) = 0, \\
\frac{1}{9} \mu L^2 (3\tilde{\alpha}_1 - 2\tilde{\alpha}_3) P'_{11}(x_2) - 2(3\tilde{\alpha}_1 + \tilde{\alpha}_3) P''_{22}(x_2) + (3\tilde{\alpha}_1 - 2\tilde{\alpha}_3) P''_{33}(x_2) \\
\quad + (M_e + M_{\text{micro}}) P_{22}(x_2) - M_e u'_2(x_2) + (\lambda_e + \lambda_{\text{micro}})(P_{11}(x_2) + P_{33}(x_2)) = 0, \]
The strain energy density for the isotropic second gradient with simplified curvature \([1,6,17,25,27]\) is

\[
W\left(Du, D^2u\right) = \mu_{\text{macro}} \left\|\text{sym } Du\right\|^2 + \frac{\lambda_{\text{macro}}}{2} u^2 \left(Du\right) + \frac{\mu}{2} \tilde{a}_1 \left\|D\left(\text{dev } Du\right)\right\|^2 + \tilde{a}_2 \left\|D\left(\text{skew } Du\right)\right\|^2 + \frac{2}{9} \tilde{a}_3 \left\|\text{tr} \left(Du\right) \right\|^2,
\]

where \(\mu\) and \(\lambda\) are the shear modulus and bulk modulus, respectively, \(u\) is the displacement, and \(\tilde{a}_1, \tilde{a}_2, \tilde{a}_3\) are the curvature coefficients. The terms \(D\left(\text{sym } Du\right)\), \(D\left(\text{dev } Du\right)\), and \(D\left(\text{skew } Du\right)\) represent the symmetric, deviatoric, and skew parts of the displacement gradient tensor, respectively. The trace of the displacement tensor \(\text{tr} \left(Du\right)\) is the total strain.

In the limit of small strain, the strain energy density reduces to

\[
W\left(Du, D^2u\right) \approx \frac{1}{2} \mu_{\text{macro}} \left\|Du\right\|^2 + \frac{1}{2} \lambda_{\text{macro}} \left\|\nabla u\right\|^2.
\]

This expression is similar to the classical linear elasticity energy density, with \(\mu_{\text{macro}}\) and \(\lambda_{\text{macro}}\) representing the macroscopic shear and bulk moduli, respectively.

### 9 Uniaxial extension problem for the second gradient continuum

The uniaxial extension problem is a fundamental problem in continuum mechanics, where a material is subjected to uniaxial tension along one direction. The problem is described by the equation

\[
\frac{\partial^2 u}{\partial x^2} = 0,
\]

with boundary conditions

\[
\frac{\partial u}{\partial x} = 0 \text{ at } x = 0, \quad u = u_0 \text{ at } x = L.
\]

The solution to this problem is

\[
u(x) = \frac{u_0}{L} x.
\]

Thus, the strain energy density for the uniaxial extension problem is

\[
W = \frac{1}{2} \mu_{\text{macro}} \left\|\frac{du}{dx}\right\|^2 = \frac{u_0^2}{2L} \mu_{\text{macro}}.
\]

For inhomogeneous and anisotropic media, the problem becomes more complex, and the solution may require numerical methods or approximations. The micro-strain model, as described in the text, provides a framework to analyze such problems by considering the effects of microstructure on the macroscopic behavior.
uniaxial extension problem symmetry the following structure of boundary conditions for the uniaxial extension are (see Fig. 1) assumed to be

\[ \mu \]

The second gradient model can be obtained from the micro-strain model by formally letting \( \mu \rightarrow \infty \). The values of the parameters used are: \( \mu = 1, \mu_{\text{macro}} = 1, \lambda_{\text{micro}} = 2, \tilde{\alpha}_3 = 4 \); (right) Displacement profile across the thickness of the dimensionless \( \bar{h} = u_2 / (\gamma h) \) for different values of \( L_c = \{0, 0.1, 0.2, 0.35, \infty\} \). The values of the other parameters used in order to maximize the nonhomogeneous behavior are \( \mu = 1, \lambda_{\text{micro}} = 1, M_{\text{micro}} = 1, \tilde{\alpha}_3 = 2 \)

while the equilibrium equations without body forces are the following:

\[
\text{Div} \left[ 2\mu_{\text{macro}} \text{sym} Du + \lambda_{\text{macro}} \text{tr} (Du) 1 \right] - \mu L_c^2 \left( \tilde{\alpha}_1 \text{dev sym} \Delta (Du) + \tilde{\alpha}_2 \text{skew} \Delta (Du) + \frac{2}{9} \tilde{\alpha}_3 \text{tr} (\Delta (Du)) 1 \right) = 0 ,
\]

where \( (\mu_{\text{macro}}, \kappa_{\text{macro}}, \mu, \tilde{\alpha}_1, \tilde{\alpha}_3) > 0 \) in order to guarantee the positive definiteness of the energy. Due to the uniaxial extension problem symmetry the following structure of \( u = (0, u_2(x_2), 0)^T \) has been chosen, which results in having only the component \( u_{2,2} \) different from zero in the gradient of the displacement \( Du \). The boundary conditions for the uniaxial extension are (see Fig. 1) assumed to be

\[
u_2(x_2) = \pm h/2 = \pm \frac{y h}{2}, \quad u_2'(x_2) = \pm h/2 = 0 .
\]

After substituting the expression of the displacement field in Eq. (61), the nontrivial equilibrium equation reduces to

\[
(\lambda_{\text{micro}} + 2\mu_{\text{micro}}) u_2''(x_2) - \frac{1}{3} \tilde{\alpha}_3 \mu L_c^2 u_2^{(4)} (x_2) = 0 .
\]

After applying the boundary conditions to the solution of Eq. (63), it results that \( u_2(x_2) \) is given by [24,26]

\[
u_2(x_2) = \frac{2x_2}{h} - \frac{2x_2}{f_1} \sinh \left( \frac{f_1 x_2}{T_c} \right) \sech \left( \frac{f_1 x_2}{T_c} \right) \frac{L_c}{T} \frac{y h}{2} , \quad f_1 := \sqrt{\frac{\lambda_{\text{micro}} + 2\mu_{\text{micro}}}{\mu \tilde{\alpha}_3/3}} .
\]

where \( f_1 > 0 \) is strictly positive in order to match the positive definiteness conditions and the same reasoning applied in the relaxed micromorphic model sections still holds. Strain energy (61) becomes then

\[
W(y) = \int_0^h W(Du, D^2u) = \frac{1}{2} \left[ \frac{M_{\text{macro}}}{\lambda_{\text{macro}} + 2\mu_{\text{macro}}} \frac{L_c}{T} \frac{h^2}{f_1^2} \right] h y^2 = \frac{1}{2} M_w h y^2 .
\]

The plot of the extensional stiffness \( M_w \) while varying \( L_c \) is shown in Fig. 5.
10 Conclusions

Only the second gradient formulation produces an unbounded apparent stiffness as $L_c \to \infty$ ($h \to 0$), while for the other models different bounded limit stiffnesses are observed. For the second gradient model, because of its unboundedness stiffness, it can be more likely to have an instability in the parameters’ fitting process on real structures; while being at a scale close to the singularity, a small changes in the geometrical or material properties of the sample may technically cause an arbitrarily large change in the values of the elastic coefficients. Therefore, the use of the second gradient model (or the classical micromorphic model in bending or torsional tests [25,27]) should be done with great care as regards the stable identification of parameters. These problems are avoided for the relaxed micromorphic model. The relaxed micromorphic model determines $\tilde{M} = \frac{M_c M_{\text{micro}}}{M_c + M_{\text{micro}}}$, which is less than $M_{\text{micro}}$ and $M_c$, while the micro-strain model determines $M_c$ as limit stiffness. The Cosserat model is not able to catch a nonhomogeneous solution and provides no size effect. The different limit stiffnesses for the relaxed micromorphic model versus the full micromorphic and micro-strain model approach, respectively, suggest that the meaning of classical experimental tests does not have an unambiguous deformation and micro-deformation solution field anymore, and this is due to the fact that we can have different boundary conditions on the components of the micro-distortion tensor depending on what each model requires to constrain. This allows the existence of different uniaxial extension-like problems and not just one like for a classical Cauchy material.

A The limit $L_c \to \infty$ for the relaxed micromorphic model

The limit of the energy, Eq. (11), for $L_c \to \infty$, requires that $\|\text{Curl } P\| = 0$, which implies that $P = D\xi$, for some $\xi : \Omega \to \mathbb{R}^3$. Energy Eq. (11) now becomes

$$ W(Du, D\xi) = \mu_e \|\text{sym}(Du - D\xi)\|^2 + \frac{\lambda_e}{2} \text{tr}^2(Du - P) + \mu_{\text{micro}} \|\text{sym} D\xi\|^2 + \frac{\lambda_{\text{micro}}}{2} \text{tr}^2(D\xi) \ , \quad (65) $$

and that Eq. (13) turns into

$$ \tilde{\sigma} = \text{Div} \left[ 2\mu_e \text{sym}(Du - D\xi) + \lambda_e \text{tr}(Du - D\xi) \right] = 0 \ , \quad (66) $$

with consistent coupling boundary condition $Du \cdot \tau = D\xi \cdot \tau$. Given Eq. (66), Eq. (66) reduces to be

$$ \text{Div} \left[ 2\mu_{\text{micro}} \text{sym} D\xi + \lambda_{\text{micro}} \text{tr} (D\xi) \right] = 0 \ , \quad (67) $$

which, for the uniaxial extension problem with boundary condition $u_2(x_2 = \pm h/2) = \pm \gamma h/2$, is equivalent to

$$ D\xi = \begin{pmatrix} 0 & 0 & 0 \\ 0 & a & 0 \\ 0 & 0 & 0 \end{pmatrix}, \quad Du = \begin{pmatrix} 0 & \gamma & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}, \quad (68) $$
where \( a \) is an arbitrary constant. This solution to Eq. (66) is therefore not unique. Inserting \( Du \) and \( D\xi \) from Eq. (68) in Eq. (65), the following energy expression is recovered

\[
I(a) = \frac{1}{2} \left( 2a^2M_{\text{micro}} + 2M_e(a - \gamma)^2 \right),
\]

which has to be minimized with respect to \( a \) in order to remove the nonuniqueness of equilibrium system Eq. (66), which means that the following relation

\[
\frac{\partial}{\partial a} \left( a^2M_{\text{micro}} + M_e(a - \gamma)^2 \right) = 2a(M_e + M_{\text{micro}}) - 2\gamma M_e = 0
\]

has to be satisfied. The solution of Eq. (70) is

\[
a_{\text{min}} = \frac{M_e}{M_e + M_{\text{micro}}},
\]

Finally it is possible to substitute \( a_{\text{min}} \) into Eq. (68) obtaining

\[
D\xi = \begin{pmatrix} 0 & 0 & 0 \\ 0 & \frac{M_e}{M_e + M_{\text{micro}}} \gamma & 0 \\ 0 & \frac{M_e}{M_e + M_{\text{micro}}} \gamma & 0 \end{pmatrix}, \quad Du = \begin{pmatrix} 0 & \gamma & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix} \tag{71}
\]

Solution Eq. (71) satisfies the equilibrium equations, the boundary conditions, and the minimum energy requirement. The expression of the energy now becomes

\[
W(\gamma) = \int_{-\frac{h}{2}}^{\frac{h}{2}} W(Du, D\xi) = \frac{1}{2} M_e M_{\text{micro}} h \gamma^2 = \frac{1}{2} \bar{M} h \gamma^2, \tag{72}
\]

with \( \bar{M} = \frac{M_e M_{\text{micro}}}{M_e + M_{\text{micro}}} \) the extensional stiffness for the relaxed micromorphic when \( L_c \to \infty \).
