PENROSE LIMITS OF HOMOGENEOUS SPACES

SIMON PHILIP

Abstract. We prove that the Penrose limit of a spacetime along a homogeneous geodesic is a homogeneous plane wave spacetime and that the Penrose limit of a reductive homogeneous spacetime along a homogeneous geodesic is a Cahen–Wallach space. We then consider several homogenous examples to show that these results are indeed sharp and conclude with a remark about the existence of null homogeneous geodesics.

1. Introduction

In [25] Penrose introduced a method for taking a continuous limit of any spacetime to a plane wave. The method effectively involves “zooming in” on a null geodesic in such a way that the metric stays nondegenerate. In [14] Güven extended the method to that of supergravity theories where it is a useful tool for generating new solutions to the supergravity equations from known ones. Since then several papers have investigated the properties of these Penrose limits, [3], [4], [5], [24].

Penrose limits have been used as evidence for the $AdS/CFT$ correspondence. The Penrose limits of the $AdS_5 \times S^5$ type $IIB$ superstring background were calculated in [5], one of which was shown to be the BFHP maximally supersymmetric plane wave background [4]. String theory in this background is exactly solvable [21], [22] giving rise to an explicit form of the $AdS/CFT$ correspondence [2] in which both the gauge theory and the gravity sides are weakly coupled, allowing many perturbative checks albeit for a restricted class of observables.

A more general class of background metrics on which string theory is exactly solvable are the homogeneous plane waves [8], [23]. Penrose limits onto homogeneous plane waves have been investigated, such as the Penrose limits of the Gödel-like spacetimes [6]. In [5] it was shown that the dimension of the isometry algebra never decreases under a Penrose limit. Hence it seemed a “natural” assumption that the Penrose limit of a homogeneous spacetime is always a homogeneous plane wave. However, in [24] it was shown that the cross product of the homogeneous Kaigorodov spacetime with a sphere has a Penrose limit which is not itself homogeneous. Consequently the aim of this paper is give necessary and sufficient conditions on a spacetime and the null geodesic that guarantee that the Penrose limit is homogeneous.

Section 2 gives the definition of the Penrose limit and proves that this definition is well–defined. We also give a proof of the covariance property of the Penrose limit stated in [5].

Section 3 gives some examples of known hereditary properties of the Penrose limit. Section 4 contains the background on homogeneous spaces needed for our results. This includes descriptions of reductive homogeneous spaces, naturally reductive homogeneous spaces, the Killing transport and homogeneous geodesics.

In section 5 we use the Killing transport to prove that the Penrose limit of a lorentzian spacetime along a homogeneous geodesic is a homogeneous plane wave. We then use a similar approach to prove that the Penrose limit of a reductive
homogeneous spacetime along a homogeneous geodesic is a reductive homogeneous plane wave.

In section 6 we use the classification of homogeneous plane waves that was given in [7] to prove that the Penrose limit of a reductive homogeneous spacetime along an absolutely homogeneous geodesic is a naturally reductive plane wave.

In section 7 we first show that the Penrose limit of a non–homogeneous spacetime can be homogeneous. Then we describe the Kaigorodov spacetime and its Penrose limits as calculated in [24]. We give an example of a Penrose limit of a reductive homogeneous space along a homogeneous geodesic for which the homogeneous structure "blows up" but the limiting spacetime is still homogeneous. We also give an example of a Penrose limit of a non–reductive homogeneous spacetime along a homogeneous geodesic which is still non–reductive homogeneous.

Finally in section 8 we show that while there must exist at least one homogeneous geodesic in any reductive homogeneous spacetime [18], [20], there may not exist any null absolutely homogeneous geodesics.

2. What is a Penrose limit?

Let \((M, g)\) be a smooth \((n+1)\)-manifold with a lorentzian metric. Let \(\gamma\) be a null geodesic of \((M, g)\). Then given a point \(x \in \gamma\) there exists a coordinate neighborhood \((U, \mu)\), \(\mu : U \rightarrow \mathbb{R}^{n+1}\), of \(x\) defining coordinates \(\mu(y) = (u(y), v(y), [y^k(y)])\), where \(u\) is a coordinate along \(\gamma\), such that in \(U\) the metric may be written as

\[
g = du dv + \alpha dv^2 + \sum_{i=1}^{n-1} \beta_i dy^i dv + \sum_{i,j=1}^{n-1} C_{ij} dy^i dy^j. \tag{1}
\]

Here \(\alpha, \beta_i, C_{ij}\) are functions of \((u, v, [y^k])\) and \((C_{ij})\) is positive definite.

To choose such coordinates one chooses a one-parameter family of hypersurfaces parameterized by \(v\) and foliated by null geodesics. The coordinate along the prescribed geodesics is given by \(u\) and \(\gamma\) is given by \((u, 0, 0)\).

In other words, one chooses a local extension of the null geodetic tangent vector-field \(\frac{\partial}{\partial u}\) of \(\gamma\) to a null geodetic vector field in a neighborhood of \(x\). Then one chooses \((n-1)\)-submanifolds on which the restricted metric is Riemannian and allows \(v\) to be the parameter labelling these submanifolds.

Let \(\Omega \in (0, \infty)\). Consider the map

\[
\psi_\Omega : \mathbb{R}^{n+1} \rightarrow \mathbb{R}^{n+1} \\
: (u, v, [y^k]) \mapsto (u, \Omega^2 v, [\Omega y^k]). \tag{2}
\]

This map induces the following change of coordinates:

\[
\phi_\Omega^U = \mu^{-1} \circ \psi_\Omega \circ \mu : U \rightarrow U. \tag{3}
\]

(If necessary, to make this well defined, we may need to shrink \(U\) so that it does not contain any “holes”.) By patching together such coordinate neighborhoods along \(\gamma\) we may think of \(\phi_\Omega\) as a diffeomorphism from a tubular neighborhood of \(\gamma\) to a tubular subneighborhood. Then we define the **Penrose limit** of \((M, g, \gamma)\) to be this tubular neighborhood together with the metric

\[
g_{Pl} = \lim_{\Omega \to 0} \Omega^{-2} (\phi_\Omega^{-1})^* g = du dv + \sum_{i,j=1}^{n-1} C_{ij}(u, 0, 0)dy^i dy^j. \tag{4}
\]
Notice that at $\Omega = 0$, $\phi_\Omega$ is no longer a diffeomorphism.

**Proposition 1.** $g_{Pl}$ is defined independently of choice of coordinates putting $g$ in the form $\mathbf{1}$.

**Proof.** Let $(r, s, [x^i])$ be a different choice of coordinates such that

$$g = drds + \rho ds^2 + \sum_{i=1}^{n-1} \psi_i dx^i ds + \sum_{i,j=1}^{n-1} \Theta_{ij} dx^i dx^j,$$

(5)

where $\rho, \psi, \Theta_{ij}$ are functions of $(r, s, [x^i])$ and $(\Theta_{ij})$ is positive definite. As both $u$ and $r$ are parameters along the geodesic $\gamma$ we may as well choose them equal $u = r$.

An easy check shows that the change of coordinates matrix must be of the form

$$
\begin{pmatrix}
  dr \\
  ds \\
  dx^i
\end{pmatrix} =
\begin{pmatrix}
  1 & 0 & 0 \\
  0 & 1 & 0 \\
  0 & c^i & e^i_k
\end{pmatrix}
\begin{pmatrix}
  du \\
  dv \\
  dy^k
\end{pmatrix},
$$

and that under this

$$\Theta_{ij} e^i_k e^j_l = C_{kl}. \quad (6)$$

In fact $c^i$ must also be zero because the second row in the matrix equation above shows that $s = v + K$, $K$ a constant, and the change of basis matrix for the dual basis to the one-forms above is the inverse transpose:

$$
\begin{pmatrix}
  \partial u \\
  \partial v \\
  \partial y^i
\end{pmatrix} =
\begin{pmatrix}
  1 & 0 & 0 \\
  0 & 1 & -c^i(e^{-1})^i_k \\
  0 & 0 & (e^{-1})^i_k
\end{pmatrix}
\begin{pmatrix}
  \partial r \\
  \partial s \\
  \partial x^k
\end{pmatrix}.
$$

As $e^i_k$ is nondegenerate we must have $c^i = 0$. Putting this into the Penrose limit metric $\mathbf{4}$

$$drds + \sum_{i,j=1}^{n-1} \Theta_{ij}(r, 0, 0) dx^i dx^j = du dv + \sum_{i,j,k,l=1}^{n-1} \Theta_{ij}(r, 0, 0) e^i_k e^j_l dy^k dy^l$$

(7)

$$= du dv + \sum_{k,l=1}^{n-1} C_{kl}(u, 0, 0) dy^k dy^l.$$

□

In the recent paper $\mathbf{3}$ a covariant description of the Penrose limit without reference to the adapted coordinates is given.

A sufficient condition for telling when two Penrose limits will be isometric is the following (the statement of this Theorem appeared in $\mathbf{5}$ although the proof did not).

**Theorem 2** (Covariance of the Penrose limit). Let $(M, g)$, $(M', g')$ be two lorentzian manifolds. Let $\gamma$ and $\gamma'$ be two null geodesics inside $M$ and $M'$ respectively. Let $f : M_\gamma \to M'_{\gamma'}$ be an isometry of tubular neighborhoods of $\gamma$ and $\gamma'$ which maps $\gamma$ onto $\gamma'$. Then the Penrose limits of $(M, g)$ and $(M', g')$ along $\gamma$ and $\gamma'$ respectively are isometric.

**Proof.** Let $(U, \mu = (u, v, [y^k]))$ be a coordinate neighborhood of a point $x$ on $\gamma$ such that the metric $g$ takes the form $\mathbf{1}$. Define a coordinate neighborhood $(f(U), \mu' = (u', v', [y'^k]))$ about $f(x)$ by

$$\mu'(f(x)) = \mu(x),$$

(8)

so that $u' = u \circ f^{-1}$ is a coordinate along $\gamma'$. As $g = f^*g'$, then $g'$ also takes the form of $\mathbf{1}$ in this neighborhood.
Now consider \( f \circ \phi_{\Omega}^{U} : U \to U' \). We have
\[
f \circ \phi_{\Omega}^{U} = f \circ \mu^{-1} \circ \psi_{\Omega} \circ \mu = f \circ (\mu' \circ f)^{-1} \circ \psi_{\Omega} \circ (\mu' \circ f) = \mu'^{-1} \circ \psi_{\Omega} \circ \mu' \circ f = \phi_{\Omega}^{U'} \circ f .
\]
Therefore
\[
g_{Pl} = \lim_{\Omega \to 0} \Omega^{-2}(\phi_{\Omega}^{U'})^{*} g = \lim_{\Omega \to 0} \Omega^{-2}(\phi_{\Omega}^{U})^{*} f^{*} g' = \lim_{\Omega \to 0} \Omega^{-2}(f \circ \phi_{\Omega}^{U'})^{*} g' = \lim_{\Omega \to 0} \Omega^{-2}(\phi_{\Omega}^{U'} \circ f)^{*} g' = \lim_{\Omega \to 0} \Omega^{-2} f^{*} \circ (\phi_{\Omega}^{U'})^{*} g' = f^{*} g'_{Pl} .
\]
\[
\Box
\]

3. HEREDITARY PROPERTIES

We say that a property of the metric \( g \) is **hereditary** if the Penrose limit \( g_{Pl} \) has the same property. For example,

**Proposition 3.** Suppose \((M, g)\) is locally symmetric/conformally flat. Then \((M_{\gamma}, g_{Pl})\) is locally symmetric/conformally flat. If \((M, g)\) is Einstein then \((M_{\gamma}, g_{Pl})\) is Ricci flat, in particular it is Einstein.

**Proof.** Let \( \nabla_{\Omega}, R_{\Omega} \) denote the connection and curvature of \( g_{\Omega} := \Omega^{-2}(\phi_{\Omega}^{-1})^{*} g \) respectively. As \( \phi_{\Omega} \) is a diffeomorphism if \( \nabla R = 0 \) then \( \nabla_{\Omega} R_{\Omega} = 0 \) for \( \Omega > 0 \). By a continuity argument we see that \( \nabla_{Pl} R_{Pl} = 0 \).

If \( Ric(g) = \lambda g \) then
\[
Ric(g_{\Omega}) = Ric(\Omega^{-2}(\phi_{\Omega}^{-1})^{*} g) = Ric((\phi_{\Omega}^{-1})^{*} g) = \lambda(\phi_{\Omega}^{-1})^{*} g .
\]
This gives
\[
Ric(g_{\Omega}) = \Omega^{2} \lambda g_{\Omega} ,
\]
and by continuity we see that \( Ric(g_{Pl}) = 0 \).

These hereditary properties can be used to easily compute the Penrose limits of anti de Sitter space \( AdS \). Anti de Sitter space is Einstein and conformally flat hence any Penrose limit is Ricci flat and conformally flat and thus flat.

In the case of \( AdS \times S \) is considered. It is a symmetric space and is shown to have two non-isometric null geodesics leading to two non-isometric Penrose limits which are flat space and a symmetric plane wave.

Another useful hereditary property is that of geodesic completeness:

**Theorem 4.** Suppose \((M, g)\) is a geodesically complete lorentzian manifold. Then the Penrose limit along any null geodesic is geodesically complete.

**Proof.** Let \( \gamma(t) \) be a geodesic with respect to \( \nabla_{Pl} \) for \( t \in [a, b] \). Without loss we may assume that \( \gamma \) is contained in a normal coordinate neighborhood of some point on \( \gamma \) so that there is a unique geodesic from \( \gamma(a) \) to \( \gamma(b) \) with respect to \( \nabla_{\Omega} \) for \( \Omega \in [0, 1] \) (which is possible because \( \nabla_{\Omega} \) varies continuously with respect to \( \Omega \) and \([0, 1]\) is compact.) . Let \( \gamma_{0} \) be the unique geodesic with respect to \( \nabla_{\Omega} \) between \( \gamma(a) \) and \( \gamma(b) \). Then \( \gamma_{\Omega}(t) \) may be extended to \( (-\infty, \infty) \) as \( \nabla_{1} \) is geodesically complete.
and \( \phi_\Omega \) is a diffeomorphism. Continuity implies that the sequence of geodesics \( \gamma(\Omega) \) for \( \Omega = \frac{1}{k} \) “converges” to \( \gamma \) in the following sense. Any neighborhood of any point on \( \gamma \) intersects all but a finite number of geodesics of the sequence. Therefore, by continuity of the geodesic equation with respect to \( \Omega \), we have that \( \gamma \) may be extended beyond \((a, b)\).

One last hereditary property, as noted in the introduction, is the following:

**Proposition 5.** The dimension of the isometry algebra of \( g_{PL} \) is no less than the dimension of the isometry algebra of \( g \).

**Proof.** See [13] or [5].

---

4. Homogeneous spaces and homogeneous structures

In this section we will give the definitions and results we need in relation to homogeneous spaces.

**Definition 6.** A connected lorentzian manifold \((M, g)\) is **homogeneous** if its group of isometries acts transitively on \( M \).

When this is the case then \( M \) can be written \( M = G/H \) where \( G \) is the group of isometries and \( H \) is a closed subgroup.

**Definition 7.** A homogeneous space \( M = G/H \) is **reductive** when there exists a subspace \( m \cong T_oM \subset g \) such that

1. \( g = h \oplus m \),
2. \([h, m] \subset m\).

It is **symmetric** if it also satisfies

\[
[m, m] \subset h.
\]

(13)

(In fact, strictly speaking this is the definition of weakly reductive. However for the rest of this paper we shall assume that \( H \) is connected, in which case they are the same thing.)

**Definition 8.** Let \( o \) denote the coset of \( H \) in \( M \) and fix a frame \( u_0 : \mathbb{R}^n \to T_oM \) of the frame bundle \( F \). Define the **linear isometry representation** \( \lambda : H \to GL(n, \mathbb{R}) \) by

\[
\lambda(h) := u_0^{-1} \circ h_* \circ u_o,
\]

where \( h \in H \), \( h_* : T_oM \to T_oM \) denotes the differential of \( h \) at \( o \).

**Theorem 9.** Let \( F \) be the frame bundle of \( M = G/H \) a reductive homogeneous space of dimension \( n \) with decomposition \( g = h \oplus m \). Then there is a one-to-one correspondence between the set of \( G \)-invariant connections in \( F \) and the set of linear maps \( \Lambda_m : m \to gl(n, \mathbb{R}) \) such that

\[
\Lambda_m(\text{ad}(h)(X)) = \text{ad}(\lambda(h))(\Lambda_m(X)),
\]

for \( X \in m \) and \( h \in H \).

The correspondence is given by

\[
\omega_{u_o}(\tilde{X}) = \begin{cases} 
\lambda(X) & \text{if } X \in h, \\
\Lambda_m(X) & \text{if } X \in m,
\end{cases}
\]

(16)

where \( \omega \) is the connection one-form, \( \tilde{X} \) is the natural lift of \( X \in g \) to \( F \) and \( \lambda \) is not only as above \( H \to GL(n, \mathbb{R}) \) but also the induced Lie algebra homomorphism \( h \to gl(n, \mathbb{R}) \).
Definition 10. The connection obtained by taking $\Lambda_m = 0$ is called the canonical connection.

The canonical connection can also be described in the following way. Let $\theta$ be the left-invariant Maurer–Cartan form of $G$

$$\theta_g(X) := (L_g)^*(X), \quad (17)$$

where $L_g$ denotes left multiplication by $g$ and $*$ denotes differentiation. Let $\sigma : U \to G$ be a local coset representative. Then the pull back of $\theta$ by $\sigma$ splits as

$$\sigma^*(\theta) = \theta^h + \theta^m, \quad (18)$$

where $\theta^h(X) \in h, \theta^m(X) \in m$. The one-form $\theta^h$ defines the connection one-form for the canonical connection.

The geodesics of the canonical connection are curves $\gamma(t)$ of the form

$$\exp(tX), \quad t \in \mathbb{R}, \quad X \in g. \quad (19)$$

If $(M, g)$ is symmetric then the canonical connection coincides with the Levi–Civita connection.

Theorem 11. The canonical connection of a reductive homogeneous space is complete.

Proof. See chapter X, Corollary 2 in [15]. □

Theorem 12 (([1], [17], [12]). Let $(M, g)$ be a reductive lorentzian homogeneous manifold with Levi–Civita connection $\nabla$. Then there exists a $(2, 1)$ tensor $T$ defining a metric connection $\tilde{\nabla} := \nabla - T$ with curvature $R$ such that $\tilde{\nabla} T = \tilde{\nabla} R = 0$.

Proof. Write $M = G/H$, with decomposition $g = h \oplus m$. Let $\nabla$ be the canonical connection of $M$. Let $T = \nabla - \tilde{\nabla}$. As $G$ acts by isometries, $\nabla$ is also $G$-invariant. Hence $T$ and $R$ are $G$-invariant. Therefore, see [15], they are both parallel with respect to $\nabla$. □

(The first version of this Theorem for riemannian signature appeared in [1]. This was re-interpreted in terms of the canonical connection in [17] and extended to the pseudo-riemannian case in [12].)

Remarks:

(1) $T$ is not necessarily the torsion of $\nabla$ (and not necessarily skew-symmetric in it lower indices.) If $\tilde{\Gamma}^{i}_{jk}$ are the Christofel symbols of $\nabla$ and $\Gamma^{i}_{jk}$ of $\nabla$ and $\tau$ is the torsion of $\nabla$ then

$$\tau^{i}_{jk} = \tilde{\Gamma}^{i}_{jk} - \tilde{\Gamma}^{i}_{kj} = \tilde{\Gamma}^{i}_{jk} - \Gamma^{i}_{jk} + \Gamma^{i}_{kj} - \tilde{\Gamma}^{i}_{kj} = -T^{i}_{jk} + T^{i}_{kj}. \quad (20)$$

i.e. $\tau$ is the skew-symmetrization of $T$. In fact $\tau(X, Y)|_m = -[X, Y]_m$, the component of $[X, Y]$ lying in $m$ where $X, Y \in m$ (see chapter X, Theorem 2.6 in [15].) Also the restriction of $T$ to $m$ is given by

$$T(X, Y)|_m = \frac{1}{2} [X, Y]_m + U(X, Y), \quad (21)$$

where $U$ is the symmetric bilinear mapping of $m \times m$ into $m$ defined by

$$2g_o(U(X, Y), Z) = g_o([X, Z]_m) + g_o([Z, X]_m, Y), \quad (22)$$

where $X, Y, Z \in m$ (see chapter X, Theorem 3.3 in [15].)
(2) If \((M,g)\) is symmetric then \(\nabla R = 0\) and we can take \(T = 0\).

Such a \(T\)-tensor is called a **homogeneous structure**. A given homogeneous manifold \(M\) may have many different homogeneous structures. Each corresponding to a different choice of groups \(G\) and \(H\). For example, the 7-sphere \(S^7 = SO(8)/SO(7) = Spin(7)/G_2 = Sp(2)/Sp(1)\). (For a review of Penrose limits from the point of view of homogeneous structures see [13].)

**Definition 13.** \((M,g)\) is called **naturally reductive** if there exists a homogeneous structure \(T\) with \(U = 0\), i.e. if \(\tau = T\).

While reductivity is a property of the isotropy representation, natural reductivity is also a property of the metric.

**Proposition 14.** Let \((M,g)\) be naturally reductive. Then the geodesics of the Levi–Civita connection coincide with the geodesics of the canonical connection.

**Proof.** Let \(\nabla\) denote the Levi–Civita connection and \(\tilde{\nabla}\) the canonical connection corresponding to the homogeneous structure \(T\) with \(U = 0\). Then \(T\) will be skew-symmetric in its lower indices and consequently
\[
\nabla_X X = \tilde{\nabla}_X X + T(X,X) = \tilde{\nabla}_X X.
\] (23)

Hence the geodesic equations for the two connections are the same. □

Theorem 12 can be rewritten and then a converse constructed:

**Theorem 15.** Let \((M,g)\) be a connected, simply connected, lorentzian manifold. Then \((M,g)\) is reductive homogeneous if and only if there exists a complete affine metric connection \(\tilde{\nabla}\) with torsion \(\tau\) and curvature \(R\) such that \(\tilde{\nabla}\tau = \tilde{\nabla}R = 0\).

**Proof.** See chapter X, Theorems 2.6–2.8 in [15]. □

Above we have Theorems 12 and 15 which describe the reductive homogeneous property in terms of a metric connection on the tangent bundle. In fact we can describe the Killing vectors of an arbitrary pseudo-riemannian manifold as parallel vector fields of a covariant derivative on an extended bundle.

Let \(X\) be a vector field on a lorentzian manifold \((M,g)\). Let \(A_X : Y \mapsto -\nabla_Y X\). Then \(X\) is a Killing vector if and only if \(A_X\) is skew-symmetric with respect to \(g\).

As a consequence of the Killing identity we also have the equation:
\[
\nabla_X A_\zeta = -R(X,\zeta)
\]

Now consider the bundle \(\mathcal{E} = TM \oplus \mathfrak{so}(TM)\). If we define a covariant derivative \(D\) on \(\mathcal{E}\) by
\[
D_X (\zeta,A) := (\nabla_X \zeta + A(X), \nabla_X A + R(X,\zeta)).
\]
Then the parallel sections of \(\mathcal{E}\) with respect to \(D\) are precisely the Killing vectors of \(g\). Thus a Killing vector is completely determined by
\[
(\zeta(p), A_\zeta(p))
\]
at any point \(p\) and by parallel translation by the covariant derivative \(D\).

Finally we make the

**Definition 16.** A geodesic \(\gamma\) is called homogeneous if it is the orbit of a 1-parameter subgroup of isometries.

**Note:** on a riemannian space this definition is equivalent to writing the geodesic in the form \(\gamma(t) = exp(tX)_o\) for some \(X \in \mathfrak{g}\) (see [19]). However, if the geodesic \(\gamma(t)\) is null one may have to change its parameterization in order to write it in the form \(exp(sX)_o\). We call a geodesic of the form \(\gamma(t) = exp(tX)_o\) an **absolutely homogeneous geodesic**. Also notice that a homogeneous geodesic is not necessarily

---

**PENROSE LIMITS OF HOMOGENEOUS SPACES 7**
a geodesic of the canonical connection as a geodesic of the canonical connection is of the form \( \exp(tX) \) with \( X \in \mathfrak{m} \). We shall call a homogeneous geodesic which is a geodesic of the canonical connection a **canonical homogeneous geodesic**.

These will be the geodesics of interest when deciding whether a Penrose limit is homogeneous or not. A useful criteria for distinguishing homogeneous geodesics is the following,

**Proposition 17.** Suppose \( M \) is a lorentzian reductive homogeneous space. The geodesic \( \gamma(t) \) with \( \gamma(0) = o \) and \( \gamma'(0) = X \in \mathfrak{g} \) is a homogeneous geodesic if and only if

\[
B(X_m, [Z, X]_m) = \lambda B(X_m, Z_m)
\]

for all \( Z \in \mathfrak{g} \) and some \( \lambda \in \mathbb{R} \). It is absolutely homogeneous if and only if \( \lambda = 0 \).

**Proof.** This is a slight generalization of the proof given in [19].

**Definition 18.** A vector \( X \in \mathfrak{g} \) which satisfies \( (24) \) is called a **geodesic vector**.

**Note:** by putting \( Z = X \) in \( (24) \), we see that if \( B \) has riemannian signature then we must have \( \lambda = 0 \).

**Remark:** Suppose \( \gamma \) is a geodesic parameterized by \( u \). If \( \gamma \) is homogeneous then there is a Killing vector \( \zeta \) such that \( \zeta_p = \gamma'_p \) at all points \( p \in \gamma \). But the geodesic vector field \( \frac{\partial}{\partial u} \) is not necessarily a Killing vector field. If the Killing vector field \( \zeta \) is given by \( \frac{\partial}{\partial t^1} \), then \( t^1 \) may not be part of a **twist–free coordinate system**; that is a coordinate system \( (t^1, \ldots, t^n) \), in which we can write the metric in the form \( g_{ij} dt^i dt^j \) such that \( d(g_{11} dt^1) = 0 \). In particular, if \( \gamma \) is a null homogeneous geodesic then we may not be able to write \( g \) in the form of (1) with \( \frac{\partial}{\partial u} \) a Killing vector.

**Proposition 19.** A geodesic \( \gamma \) is homogeneous if and only if there exists a solution \((\gamma, A)\) to the Killing transport equations with \( A(\gamma') = 0 \).

5. **Penrose limits along homogeneous geodesics**

In this section we will give three Theorems which give sufficient conditions for homogeneity to be hereditary.

**Theorem 20.** The Penrose limit along a null geodesic \( \frac{\partial}{\partial u} \) which is a Killing vector is flat.

**Proof.**

\[
0 = 2 \frac{\partial}{\partial u} g = d(\frac{i}{\partial u} g) + i \frac{\partial}{\partial u} dg
\]

\[
= d(dv) + \frac{\partial \alpha}{\partial u} dv^2 + \frac{\partial \beta_i}{\partial u} dy^i dy^i + \frac{\partial C_{ij}}{\partial u} dy^i dy^j dy^j.
\]

Therefore \( C \) is independent of \( u \) and hence \( g_{\text{Pl}} \) is flat.

**Theorem 21.** The Penrose limit of a lorentzian metric along a homogeneous geodesic \( \gamma \) is homogeneous.

**Proof.** On a plane wave \( ds^2 = du dv + C_{ij} dy^i dy^j \), we have the Killing vectors

\[
\frac{\partial}{\partial v}, \frac{\partial}{\partial y^1}, \ldots, \frac{\partial}{\partial y^{n-1}}
\]

which are independent at each point \( p \). So to prove \( g_{\text{Pl}} \) is locally homogeneous it is enough to show it has a Killing vector which agrees with \( \frac{\partial}{\partial u} = \gamma' \) at \( p \).

Suppose that \( \zeta \) is a Killing vector such that \( \zeta|_\gamma = f \frac{\partial}{\partial u}|_\gamma \). Then \( \zeta|_\gamma \) is generated by Killing transport of \((\zeta(p), A_\zeta(p))\) along \( \gamma \). Now by definition,

\[
(A_\zeta f \gamma')|_\gamma = (A_\zeta \zeta)|_\gamma = 0,
\]
where by $|_{\gamma}$ we mean restriction to $\gamma \in M$, not restriction of the tangent bundle. Therefore, if we write $A_\zeta$ in components:

$$A_\zeta = \sum_{i,j} (A_\zeta)^{ij}_i \, dx^i \otimes \frac{\partial}{\partial x^j},$$

we see that

$$(A_\zeta)^{ij}_u \, |_{\gamma} = (A_\zeta)^{ij}_u \, |_{\gamma} = 0.$$ 

Also, as $\zeta$ is a Killing vector, we have

$$g \left( A_\zeta \frac{\partial}{\partial y^i}, \frac{\partial}{\partial y^j} \right) \, |_{\gamma} = -g \left( \frac{\partial}{\partial y^i}, A_\zeta \frac{\partial}{\partial u} \right) \, |_{\gamma} = 0 .$$

Therefore,

$$(A_\zeta)^{ij}_u \, |_{\gamma} = 0 .$$

Now consider the pull-back of the Killing transport covariant derivative under the Penrose limit map $\phi_\Omega$:

$$(\phi_\Omega^{-1})^* D_\zeta(X) \, |_{\gamma} = (\phi_\Omega^{-1})^* \nabla_\zeta(X) \, |_{\gamma} - (\phi_\Omega^{-1})^* A_\zeta(X) \, |_{\gamma} .$$

The components of $A_\zeta \, |_{\gamma}$ scale under the Penrose limit map in the following way:

$$(A_\zeta)^{ij}_u \, |_{\gamma} \to \Omega^{-1} (A_\zeta)^{ij}_u \, |_{\gamma}$$

$$(A_\zeta)^{ij}_u \, |_{\gamma} \to \Omega^{-2} (A_\zeta)^{ij}_u \, |_{\gamma}$$

$$(A_\zeta)^{ij}_u \, |_{\gamma} \to \Omega^{-1} (A_\zeta)^{ij}_u \, |_{\gamma}$$

and other components which either stay constant or tend to zero as $\Omega \to 0$. Taking the limit as $\Omega \to 0$ we see from above that the three components of $A_\zeta$ that could “blow up” are in fact zero. Therefore

$$(D_{Pl})_\zeta(X)(u, v, y) := \lim_{\Omega \to 0} [D_\zeta(X)(u, 0, 0)]$$

is well-defined and along with

$$(D_{Pl})_\zeta(A) := (\nabla_{Pl})_\zeta A - R_{Pl}(\zeta, X) ,$$

defines a Killing transport covariant derivative on along $\gamma$ with respect to $g_{Pl}$. Therefore, parallel translation by $D_{Pl}$ along $\gamma$ generates the remaining Killing vector needed.

**Corollary 22.** If $\gamma$ is an (absolutely) homogeneous geodesic of $g$ then it is also an (absolutely) homogeneous geodesic of the Penrose limit of $g$ along $\gamma$.

When $(M, g)$ is a reductive homogeneous manifold we can use the same strategy as above to construct a homogeneous structure on the Penrose limit:

**Proposition 23.** The Penrose limit of a reductive lorentzian homogeneous manifold along a canonical homogeneous geodesic is locally reductive homogeneous.

**Proof.** Let $(M, g)$ be a reductive homogeneous space with a null homogeneous geodesic $\gamma$. From the Ambrose–Singer Theorem we have a connection $\nabla$ such that $\nabla T = \nabla R = 0$. Let $M_{\gamma}$ be a tubular neighborhood of $\gamma$ as above and consider $\phi_\Omega(M_{\gamma})$. Now $\phi_\Omega$ is a diffeomorphism for $\Omega \neq 0$ so $\phi_\Omega(M_{\gamma})$ is reductive homogeneous for $\Omega > 0$. This defines the metric connection

$$\nabla_\Omega := (\phi_\Omega^{-1})^* \nabla = (\phi_\Omega^{-1})^* \nabla - (\phi_\Omega^{-1})^* T .$$

(25)

$\gamma$ is a homogeneous geodesic of $(M, g)$ so $T$ is a tensor of type $(2, 1)$

$$T = \nabla - \nabla = \sum_{i,j,k=1}^{n+1} T^k_{ij} \, dx^i \otimes dx^j \otimes \frac{\partial}{\partial x^k} .$$

(26)
Under the Penrose limit map $\phi_\Omega$ the coefficients scale in the following way

\[
T_{uv}^w \mapsto \Omega^{-1}T_{uv}^w|_\gamma \quad T_{uu}^v \mapsto \Omega^{-2}T_{uu}^v|_\gamma \quad T_{uy}^y \mapsto \Omega^{-1}T_{uy}^y|_\gamma ,
\]

and terms which either remain the same or tend to 0 in the limit $\Omega \to 0$.

Suppose that $\gamma$ is a canonical homogeneous geodesic. Then there is a Killing vector $\zeta$ such that $\zeta|_\gamma = \int \frac{\zeta}{\mu}|_\gamma$. Then $\zeta|_\gamma$ is generated by parallel transport by the canonical connection of $\zeta(p)$ along $\gamma$. Now by definition,

\[(\nabla_{\gamma'} \gamma')|_\gamma = 0 \quad \text{and} \quad (\tilde{\nabla} \zeta)|_\gamma = 0\]

where by $|_\gamma$ we mean restriction to $\gamma \in M$ not restriction of the tangent bundle. Thus

\[0 = (\tilde{\nabla}_f \gamma)\gamma = (\nabla_{f \gamma'} f \gamma')|_\gamma - T(f \gamma', f \gamma')|_\gamma = f df(\gamma')|_\gamma - f^2 T(\gamma', \gamma')|_\gamma,\]

and therefore,

\[T_{uy}^y|_\gamma = T_{vu}^u|_\gamma = 0.\]

Also, as $\tilde{\nabla}$ is metric we have

\[0 = (\tilde{\nabla}_W g)(X,Y) = (\nabla_W g)(X,Y) + g(T_W X,Y) + g(X, T_W Y) + g(T_W X,Y) + g(X, T_W Y) , \tag{27}\]

as $\nabla$ is metric. Hence using (1) we see that

\[T_{uv}^u|_\gamma = 0. \tag{28}\]

The Levi–Civita connection of the Penrose limit along $\gamma$, $\nabla_{Pl}$, is equal to

\[\lim_{\Omega \to 0} (\phi_{\Omega}^{-1})^* \nabla. \tag{29}\]

Also above shows that the limit $T_{Pl}|_\gamma := \lim_{\Omega \to 0} (\phi_{\Omega}^{-1})^* T|_\gamma$ is well defined on $\gamma$. Thus, by (29), the limit $\tilde{\nabla}_{Pl}|_\gamma := \lim_{\Omega \to 0} \tilde{\nabla}_{\Omega}|_\gamma$ is well defined. Now

\[\{\tilde{\nabla}_{\Omega}|_\gamma g_{Pl}|_\gamma \mid \Omega \in [0, 1]\}\]

is a continuous path in the space of tensors of type $(3, 0)$ on $\gamma$. Therefore continuity shows $\tilde{\nabla}_{Pl}|_\gamma g_{Pl}|_\gamma = 0$. Similarly

\[\tilde{\nabla}_{Pl}|_\gamma g_{Pl}|_\gamma = \tilde{\nabla}_{Pl}|_\gamma T_{Pl}|_\gamma = \tilde{\nabla}_{Pl}|_\gamma R_{Pl}|_\gamma = 0. \tag{30}\]

Define $\tilde{\nabla}_{Pl}(u,v,y^i) := \tilde{\nabla}_{Pl}|_\gamma (u,0,0)$. We have $g_{Pl}$ is independent of $v,y^i$ so

\[\tilde{\nabla}_{Pl} g_{Pl} = \tilde{\nabla}_{Pl} T_{Pl} = \tilde{\nabla}_{Pl} R_{Pl} = 0. \tag{31}\]

Applying Theorem 15 gives the result. \hfill $\square$

**Corollary 24.** A homogeneous structure $T$ has a well–defined Penrose limit along a null geodesic $\gamma(t)$ if and only if $\gamma(t)$ can be re–parameterized to a geodesic of the canonical connection with respect to $T$.

**Proof.** $T$ has a well–defined limit if and only if $T_{uu}^u|_\gamma = T_{uu}^u|_\gamma = 0$. The proof of Proposition 23 shows that this is the case if and only if $\gamma$ can be re–parameterized to a geodesic of the canonical connection. \hfill $\square$
6. Homogeneous Plane Waves

We can learn more about the hereditary properties of homogeneity by studying the space of homogeneous plane waves. In [7], Blau and O’Loughlin have classified all homogeneous plane waves into two classes. The first class consists of complete metrics and the second class incomplete metrics:

**Theorem 25** (Blau–O’Loughlin [7]). There are two classes of homogeneous plane waves:

1. \( g = 2dx^+ dx^- + (e^{x^+} A_0 e^{-x^+} f)_{ij} z^i z^j (dx^+)^2 + \sum_i (dz^i)^2 \). Complete metrics.
2. \( g = 2dx^+ dx^- + (e^{f \log x^+} A_0 e^{-f \log x^+})_{ij} z^i z^j (dx^+)^2 + \sum_i (dz^i)^2 \). Incomplete metrics (singularity along \( x^+ \)).

The isometry algebra of the generic homogeneous plane wave is given by:

\[
[e_i, Y_j] = \delta_{ij} Z, \quad [e_i, X] = -Y_i, \\
[Y_i, Y_j] = 2cf_{ij} Z, \quad [X, Z] = aZ \\
[X, Y_i] = (a\delta_{ij} + 2f_{ij}) Y_j + (c(a + b)^2 (A_0)_{ij} - af_{ij} - f_{ik} f_{kj}) e_i
\]

Here \((A_0)_{ij}\) is symmetric and \(f_{ij}\) skew–symmetric. The isotropy is generated by the \(e_i\)’s. From this it is clear that homogeneous plane waves are reductive. The non–singular plane waves have an isometry algebra with \(b = c = 1\) and \(a = 0\), while the singular plane waves have an algebra with \(a = c = 1\) and \(b = 0\). By calculating the homogeneous structure associated to these reductive splittings we see that the non–singular plane waves are naturally reductive, while the singular plane waves are not.

Contained in the class of naturally reductive plane waves are the symmetric plane waves, also called the Cahen–Wallach spaces (see [9] for the original paper or [10].) These are given by taking \(f_{ij} = 0\) in (1) of Theorem 25 and can be diagonalised to the form:

\[ g = 2dx^+ dx^- + \sum_i A_i (z^i)^2 (dx^+)^2 + \sum_i (dz^i)^2 \]

with \(A_i\) constant.

Combining this classification with Corollary 22 we obtain the

**Theorem 26.** The Penrose limit of a lorentzian space along an absolutely homogeneous geodesic is a naturally reductive plane wave.

Also we have the

**Proposition 27.** The Penrose limit of a geodesically complete lorentzian metric \(g\) along a homogeneous geodesic is naturally reductive homogeneous.

**Proof.** If \(g\) is geodesically complete then the Penrose limit is complete. The classification of homogeneous plane-waves shows that a complete homogeneous plane-wave is naturally reductive. \(\Box\)

7. Examples

In this section we will give some examples to show that the above Theorems cannot be strengthened any further.

First we will show that the converse to Theorem 21 is not true, i.e. we give an example which shows that the Penrose limit of a non–homogeneous geodesic in a non–homogeneous space may be homogeneous. Consider the metric

\[ g = 2dudv + udv^2 + \sqrt{u} \sum_i (dx^i)^2. \]
This is an incomplete and non–homogeneous metric with no Killing vector in the \( \partial_\mu \) direction. Therefore the null geodesic given by \( \partial_\mu \) is not homogeneous. However the Penrose limit of \((g, \partial_\mu)\) is given by

\[
2dudv + \sqrt{u} \sum_i (dx^i)^2.
\]

This is a reductive plane wave [23].

Next we will consider non–homogeneous geodesics in a homogeneous space. In [24] Patricot calculated the Penrose limits of the Kaigorodov space \( K_{n+3} \) which is \( \mathbb{R}^{n+3} \) together with the metric:

\[
g_{n+3} = e^{-2nL_\rho dx^2} + e^{4L_\rho (2dxdt + \sum_{i=1}^n (dy^i)^2)} + d\rho^2,\]

where \( L = \frac{1}{2} \sqrt{-\Delta_{n+2}} \).

This is a homogeneous space whose isometries are generated by

\[
K_{(0)} = \frac{\partial}{\partial t}, \quad K_{(x)} = \frac{\partial}{\partial x}, \quad K_{(i)} = \frac{\partial}{\partial y^i}, \quad L_i = x^i \frac{\partial}{\partial y^i} - y^i \frac{\partial}{\partial t},
\]

\[
L_{ij} = y^i \frac{\partial}{\partial y^j} - y^j \frac{\partial}{\partial y^i}, \quad J = \frac{\partial}{\partial \rho} - at \frac{\partial}{\partial t} - bt \frac{\partial}{\partial x} - ct \frac{\partial}{\partial y^i},
\]

Here \( a = (n + 4)L, b = -nL \) and \( c = 2L \).

| \(|\.|\) | \(L_v\) | \(L_{uv}\) | \(K_0\) | \(K_x\) | \(K_i\) | \(J\) |
|---|---|---|---|---|---|---|
| \(L_v\) | 0 | 0 | 0 | 0 | 0 | 0 |
| \(L_{st}\) | \(\partial_{st}L_{tv} + \partial_{tv}L_{sv} - \partial_{sv}L_{stv}\) | \(L_{stuv}\) | 0 | \(\delta_{st}K_v - \delta_{tv}K_u\) | \(\delta_{st}K_i - \delta_{st}K_i\) | \(c - a\) \(L_v\) |
| \(K_0\) | 0 | 0 | 0 | 0 | 0 | 0 |
| \(K_x\) | 0 | 0 | 0 | 0 | 0 | 0 |
| \(K_i\) | \(\delta_{si}K_0\) | \(\delta_{si}K_v - \delta_{si}K_u\) | 0 | 0 | 0 | \(-cK_i\) |
| \(J\) | \((a - c)L_v\) | 0 | \(aK_0\) | \(bK_x\) | \(cK_i\) | 0 |

where \( L_{stuv} = -\delta_{su}L_{tv} + \delta_{tu}L_{sv} - \delta_{tv}L_{stv} + \delta_{tv}L_{stv} \). This isometry algebra is the semidirect product of an extended Heisenberg algebra and \( \mathfrak{so}(n) \) and has dimension \((2n + 3) + \frac{1}{2}n(n + 1)\). The homogeneous space as given by the full isometry group is non–reductive. However, the transitive subgroup which is generated by \( K_0, K_x, K_i \) and \( J \) gives \( K_{n+3} \) as a reductive homogeneous space.

\( K_{n+3} \) has 3 non–isometric Penrose limits. The first is along a Killing vector and is thus flat. The second along a homogeneous geodesic is a reductive homogeneous plane wave and the third is along a non–homogeneous geodesic is non–homogeneous.

Patricot also considered the space \( K_{n+3} \times S^d \) where \( S^d \) is sphere with round metric which is again a non–reductive homogeneous space. It has four non-isometric Penrose limits. Three along geodesics which are constant on the sphere and hence have the same Penrose limits as \( K_{n+3} \): the flat metric and a reductive plane wave and a non–homogeneous metric. The fourth Penrose limit is along a non-homogeneous geodesic which wraps around the sphere and \( K_{n+3} \) and is also a non-homogeneous plane wave.

Thus the Penrose limit of a non-reductive homogeneous space along a non-homogeneous geodesic is not necessarily homogeneous. The next example will illustrate the existence of non–canonical homogeneous geodesics and will show that the Penrose limit of a homogeneous structure along such a curve will blow up.

B. Komrakov Jr has compiled a complete classification of 4-dimensional pseudo-riemannian homogeneous spaces [19]. In his paper he considers the isotropy representation \( \rho: \mathfrak{h} \to \mathfrak{gl}(\mathfrak{g}/\mathfrak{h}) \) of a homogeneous space \( G/H \) and classifies first all the complex forms and then the real forms of the subalgebra \((\rho(\mathfrak{h}))^C \subset \mathfrak{so}(4, \mathbb{C})\).
The result is a list of the possible Lie algebras \( g \) and chosen subalgebras \( h \) and the associated isotropy representation given as a matrix.

We can then use the Maurer–Cartan form to recover the metric from \( B \). We summarize below some of the properties of this classification:

- Number of isotropy representations admitting Riemannian metrics: 6
- Number of isotropy representations admitting lorentzian metrics: 14
- Number of isotropy representations admitting metrics of \((2, 2)\) signature: 30
  (There is some overlap in these cases where a representation admits metrics of different signatures.)
- Number of symmetric/reductive algebras admitting a Riemannian metric: \( \frac{21}{29} \)
- Number of symmetric/reductive/nonreductive algebras admitting a lorentzian metric: \( \frac{35}{64} / 6 \)
- Number of symmetric/reductive/non-reductive algebras admitting a metric of \((2, 2)\) signature: \( \frac{57}{123} / 9 \)

By studying Komrakov’s list we see that there does not exist a 4–dimensional Lorentzian homogeneous space with a non–canonical homogeneous geodesic. However there do exist 5–dimensional examples as we will now show. Consider the algebra (Komrakov number 1.12.11 extended by a central element.)

\[
\begin{bmatrix}
1 & 0 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 & 0 \\
0 & 0 & 1 & 0 & 0 \\
0 & 0 & 0 & 1 & 0 \\
0 & 0 & 0 & 0 & -1
\end{bmatrix}
\]

This defines a reductive homogeneous space \( G/H \) with \( m \) the span of \{\( u_1, u_2, u_3, u_4, u_5 \)\} and \( h \) spanned by \( e_1 \). The corresponding isotropy representation is skew–symmetric with respect to the bilinear form \( B \):

\[
\sigma = \exp(x_1 u_1) \exp(x_2 u_2) \exp(x_3 u_3) \exp(x_4 u_4) \exp(x_5 u_5) : M \to G ,
\]

and calculate the Maurer–Cartan form

\[
\sigma^{-1} d\sigma = \cosh(2x_3) dx_1 u_1 \\
+ (x_4 \sinh(2x_3) dx_1 + x_2 \cosh(x_3) dx_1 + \cosh(x_3) dx_2 + x_4 dx_3) u_2 \\
+ dx_3 u_3 \\
+ (-x_4 \cosh(2x_3) dx_1 - 2 \sinh(2x_3) dx_1 - x_3 \sinh(x_3) dx_1 - \sinh(x_3) dx_2 + dx_4) u_4 \\
+ dx_5 u_5 .
\]

The metric is given by \( B((\sigma^{-1} d\sigma)_m, (\sigma^{-1} d\sigma)_m) \). The non–zero components of the homogeneous structure \( T \) restricted to the subspace \( m \) are given by:
\[1 = T_{414} = T_{221} = T_{243} = T_{244} = T_{424},\]
\[-1 = T_{212} = T_{234} = T_{432} = T_{441}.\]

Now consider the vector \( U = u_2 + \frac{1}{\sqrt{2}} u_3 + \sqrt{2} u_5 + \sqrt{3} e_1. \) This is an absolutely geodetic vector and hence generates a homogeneous geodesic. However this geodesic is not a geodesic of the canonical connection and thus the Penrose limit of the homogeneous structure along \( \exp(tU)(p) \) will blow up:

\[T(U,U)|_m = u_1 - \frac{1}{2} u_4 \xrightarrow{p} \infty.\]  

(36)

However, the algebra \( \mathfrak{g} \) has the following transitive subalgebra:

| \([,]\)  | \(U\)  | \(u_1\)  | \(u_2\)  | \(u_4\)  | \(u_5\)  |
|-------|--------|--------|--------|--------|--------|
| \(U\) | 0      | 2\(U\) | 3\(u_2\) | \(\sqrt{2}u_4\) | 0      | 0      |
| \(u_1\) | \(-2U + 3u_2\) | 0 | \(u_2\) | \(-u_4\) | 0      | 0      |
| \(u_2\) | \(\sqrt{2}u_4\) | \(-u_2\) | 0 | 0 | 0      | 0      |
| \(u_4\) | 0 | \(u_4\) | 0 | 0 | 0      | 0      |
| \(u_5\) | 0 | 0 | 0 | 0 | 0      | 0      |

The non–zero components of the homogeneous structure are given by

\[-1 = T_{U12} = T_{141},\]
\[1 = T_{221} = T_{21U} = T_{412} = T_{414},\]
\[\frac{1}{\sqrt{2}} = T_{U24} = T_{24U}.\]

This homogeneous structure does not blow up under the Penrose limit along \( U \).

It is not clear that every homogeneous geodesic is canonical with respect to some reductive decomposition as in this case. However, this is true for all the null homogeneous geodesics of 4–dimensional lorentzian homogeneous spaces.

Finally we will show that we can not replace homogenous with reductive in the result on Penrose limits of lorentzian metrics along homogeneous geodesics. Consider the incomplete, nonreductive plane wave metric

\[dudv + u^{2\mu}(dy^i)^2.\]

This is part of Blau and O’Loughlin’s classification of homogeneous plane waves. It has a singularity at \( u = 0 \) for \( \mu \neq 0 \). The vector field

\[X = -u \frac{\partial}{\partial u} + v \frac{\partial}{\partial v} + 2\mu y^i \frac{\partial}{\partial y^i}\]

is a Killing vector and thus the geodesic defined by \( \partial_u \) is a homogeneous geodesic. The trivial Penrose limit along this geodesic gives the same metric and therefore shows that the Penrose limit of a non-reductive space along a homogeneous geodesic is not necessarily reductive.

8. THE EXISTENCE OF HOMOGENEOUS GEODESICS

Finally we would like to make a remark on the existence of null homogeneous geodesics. The following Theorem has been proven in [18], [20].

**Theorem 28** (Kowalski–Szenthe). Every homogeneous Riemannian manifold admits at least one homogeneous geodesic through every point.

Since every homogenous Riemannian manifold is reductive (see [20]) it appears that this Theorem is also true in the case of reductive lorentzian manifolds.
Proposition 29. Every reductive homogeneous lorentzian manifold admits at least one homogeneous geodesic through every point.

In fact all lorentzian homogeneous examples known to the author (and this includes all 4-dimensional homogeneous spaces appearing on Komrakov’s list,) contain at least one null homogeneous geodesic although not all of them contain an absolutely homogeneous one as the following example (Komrakov number 1.1²) shows: together with the bilinear form

\[
\begin{bmatrix}
0 & u_3 & 0 & -u_1 & 0 \\
-u_3 & 0 & 0 & -u_2 & u_1 \\
0 & 0 & 0 & 0 & 2u_2 \\
u_1 & u_2 & 0 & 0 & u_3 \\
0 & -u_1 & -2u_2 & -u_3 & 0
\end{bmatrix}
\]

This is a reductive algebra and so using Proposition [17] it can be shown that the homogeneous space derived from this algebra and bilinear form has no null absolutely homogeneous geodesics. (This is in fact effectively the only 4-dimensional lorentzian homogeneous space without any null absolutely homogeneous geodesics.) However it does have a family of null homogeneous geodesics.

\[
U = Au_4 \pm Au_2 + Be_1 \quad \text{and} \quad \lambda = -2A \quad \text{with} \quad A, B \in \mathbb{R}
\]

or

\[
U = Au_2 + Bu_3 + Cu_4 \quad \text{and} \quad \lambda = -C \quad \text{with} \quad A^2 + B^2 = C^2, \quad A, B, C \in \mathbb{R}.
\]

To the author’s knowledge there are no known results about the existence of homogeneous geodesics in the nonreductive case.

9. ACKNOWLEDGMENTS

We are very grateful to Jose Figueroa-O’Farrill for help and encouragement throughout the research and writing up of this paper. We would also like to thank Patrick Meesseen for his invaluable correspondence, Harry Braden for drawing our attention to [26] and to José Antonio Oubiña for early useful correspondence.

This research was funded by an EPSRC Postgraduate studentship.
