Abstract

We propose an accurate tight-binding parametrization for the band structure of MoS$_2$ monolayers near the main energy gap. We introduce a generic and straightforward derivation for the band energies equations that could be employed for other monolayer dichalcogenides. A parametrization that includes spin–orbit coupling is also provided. The proposed set of model parameters reproduce both the correct orbital compositions and location of valence and conductance band in comparison with \textit{ab initio} calculations. The model gives a suitable starting point for realistic large-scale atomistic electronic transport calculations.

Keywords: MoS$_2$, band structure, tight-binding model, transition metal dichalcogenides

(Some figures may appear in colour only in the online journal)

1. Introduction

The synthesis of graphene in 2004 [1, 2], the first single-atom thick material, has boosted the research in atomically thin two-dimensional (2D) materials. The ability to manipulate isolated single atomic layers and reassemble them to form heterostructures layer-by-layer in a precise sequence, opens enormous possibilities for applications [3–6]. Along this approach, semiconducting dichalcogenides are promising compounds since they can be easily exfoliated and present a suitable small gap both in bulk and as a single layer. In this category of 2D dichalcogenides systems, monolayer molybdenum disulfide (MoS$_2$) has recently gained attention for combining an electron mobility comparable to that of graphene devices with a finite energy gap [7]. Unlike its bulk form, which is an indirect gap semiconductor, monolayer MoS$_2$ has a direct gap [3, 8], making it very interesting for optoelectronics. Another interesting feature is that the electronic properties appear to be highly sensitive to external pressure [9], strain [10–12], and temperature [13], which affect the gap and, under certain conditions, can also induce a insulator/metal transition. In addition, the lack of lattice inversion symmetry together with spin–orbit coupling (SOC) leads to coupled spin and valley physics in monolayers of MoS$_2$ and other group-VI dichalcogenides [14, 15], making it possible to control spin and valley in these materials [5, 16]. Due to their peculiar band structure, a variety of nanoelectronics applications [4, 5] including valleytronics, spintronics, optoelectronics, and room temperature transistor devices [7] have been suggested for monolayers of MoS$_2$.

In light of the growing interest in this material, an accurate and yet reasonably simple model describing the band structure and electronic properties of MoS$_2$ is highly desirable. So far the electronic properties of single-layer and few-layer dichalcogenides have been mainly investigated by means of \textit{ab initio} calculations, based on Density Functional Theory (DFT) [10, 16]. Such methods provide valuable information about electronic properties of pristine dichalcogenide crystals, but are computationally prohibitive to treat disordered systems with a large number of atoms. To address the latter, one needs to resort to a simple effective model, such as the \textit{kp} Hamiltonian (see, for instance, [17] for a review the \textit{kp} theory for two-dimensional transition metal dichalcogenides) or the tight-binding approximation. In this paper we choose the latter route, which provides a more accurate description for the entire band structure than the \textit{kp} method. From the computational point of view, tight-binding models are highly scalable and therefore suited to address large structures, both ordered and disordered. Hence, the tight-binding model applied to a single-layer MoS$_2$ as well as to similar transition metal dichalcogenides, constitutes a key tool for further studies of the low-energy electronic transport properties of these materials, such as the description of the conductivity in diffusive samples, as well as for evaluating the conductance of ballistic samples as a function of carrier concentration.

In recent years, a variety of tight-binding models have been proposed for MoS$_2$ monolayers [18–20]. Unfortunately, they
are neither practical nor sufficiently accurate for transport calculations. For that purpose, one needs a tight-binding model with a manageable number of parameters and interactions that accurately reproduces the *ab initio* electronic properties of the conduction band (CB) near its maximum points and the valence band (VB) near its minimal points. Before we present our results, let us now briefly review the main features of the tight-binding models for dichalcogenides found so far in the literature.

An ‘all orbital model’ was put forward by Zahid and collaborators [18]. The model includes non-orthogonal $sp^3d^5$ orbitals, considers only nearest-neighbour hopping matrix elements, and includes spin orbit coupling. The model has 96 fitting parameters. The optimization of the Slater–Koster energies [21] and overlap integrals used in the model are obtained by a fit to the DFT target band structure. The model shows good agreement with band structure calculations using the HSE06 functional [22, 23], but its computational cost and complexity make it impractical for studying disorder and electronic transport at large scales.

In contrast, Liu and collaborators [19] proposed a three-orbital tight-binding model. The authors consider a superposition of orbitals $d_{z^2}$, $d_{xy}$, and $d_{x^2−y^2}$ as orthogonal basis, targeting the main orbital composition around the $K$ point, which corresponds to the direct gap. Thus, the agreement between their first nearest-neighbour tight-binding model and the DFT predictions using both the local density approximation (LDA) [24, 25] and the generalized-gradient approximation (GGA) [26] is limited to features in the vicinity of the $K$ point, missing the local band minimal at the $Q$ point. By including up to the third-nearest neighbour hopping involving Mo–Mo terms, the agreement with the DFT-GGA band structure improves substantially. This is achieved at the expense of increasing the complexity of the model, as the number of fitting parameters goes from 8 to 19. In transport calculations, the inclusion of higher neighbour hopping terms implies in an increase in the size of the unit cell. Hence, trading a larger number of bands with nearest-neighbour hopping for a simpler model with longer range hopping is not necessarily advantageous. Moreover, the orbital composition in [19] is, by construction, restricted to Mo orbitals which limits the analysis of disorder effects. It is also worth noting that [19] fails to reproduce the orbital composition and energy spectrum around the $\Gamma$ point, which plays a significant role in transport for hole-doped monolayers.

A seven-orbitals tight-binding parametrization has been introduced by Rostami and collaborators [20]. The model considers a non-orthogonal basis and neglects the $s$ and $p_z$ orbitals of the S atoms and the $s$, $d_{xy}$, and $d_{xz}$ orbitals of the Mo atom by invoking arguments based on crystal symmetry and the range of energies of interest. The model reproduces the main features around the $K$ point, but two unrealistic flat bands appear in the gap region. We attribute this undesired feature to the fact that the $p_z$ orbital of the S atoms is not actually decoupled from other orbitals and can not be neglected. On the contrary, the $p_x$ orbital from S atoms plays a pivotal role in the transition from a direct to an indirect gap, when passing from a monolayer to a multilayer system. The basis set introduced in [20] does not distinguish between $p_z^S$ and $p_y^S$. $S$ orbitals at the top and bottom planes of the $S$–Mo–$S$ layers. Therefore, it can not correctly capture the symmetry under inversion of the $z$-axis.

As pointed out by Cappelluti and collaborators [27], the linear combination of $p_z^S$ and $p_y^S$ orbitals is necessary to produce $z$-symmetric and $z$-antisymmetric states. For this reason, [27, 28] propose a minimal model of 11 orbitals. This is also our choice. This model considers an orthogonal basis composed of all the 4$d$ Mo orbitals and the 3$p$ S orbitals, forming real symmetric (even) and antisymmetric (odd) combinations of $p_{x,y,z}$ orbitals [29, 30]. The tight-binding parameters found in [27, 28] yield two bands that look very similar to the conduction and the valence bands obtained by standard DFT calculations. However, in our treatment, by using analytical expressions for the valence and conductance bands at high-symmetry $k$-points, we observe that the tight-binding orbital compositions of [27, 28] have actually no relation with those calculated using DFT. Hence, a new tight-binding parametrization, reproducing both energies and orbital composition is badly needed. This is the main goal of this paper. We rederive the tight-binding equations of [27] in a more direct and transparent way, allowing us to more carefully consider the orbital composition in our parameter optimization procedure.

The paper is organized as follows. In section 2 we describe the atomic structure of a MoS$_2$ monolayer and discuss the DFT-HSE06 results for the the band structure that will be the reference for our tight-binding model. In section 3 we present the model. In section 4 we analyze the band equations for a few high-symmetry $k$-points, allowing us to obtain simple analytical expressions for the bands. These are used to find the best set of tight-binding parameters that fit the DFT band structure. In section 5 we present the optimized parameters and the corresponding band structure. In Section 6 we consider a simplified model with a reduced number of parameters. In section 7 we add spin–orbit interaction to the full model. Finally, in section 8 we draw our conclusions.

The main text is supplemented by a number of appendices containing technical aspects of the calculations. In appendix A we present in detail all the elements required to construct the tight-binding band equations. In appendix B we show how to implement the band equations in the unsymmetrized and symmetrized ones. Appendix C analyzes the band structure at symmetry points used in the optimization. Finally, in appendix D we present a comparison between our 11-band tight-binding formulation and that of [27, 28].

### 2. Crystal structure and *ab initio* electronic structure

Molybdenum disulfide is a layered transition metal dichalcogenide semiconductor. The layered structure is formed by a honeycomb arrangement of Mo and S atoms stacked together and forming S–Mo–S sandwiches coordinated in a triangular prismatic fashion. The S–Mo–S layers are bonded together by weak van der Waals forces.
The single-layer MoS$_2$ lattice structure is shown in figure 1, top and lateral views. It is a 2D rhombic lattice with a three-atom basis (one Mo and two S). The two Bravais primitive lattice vectors are

$$\mathbf{R}_1 = (a, 0, 0)$$

and

$$\mathbf{R}_2 = \left(\frac{a}{2}, \frac{\sqrt{3}}{2}a, 0\right).$$

where $a = 3.16$ Å is the lattice constant. The S atoms are located in planes 1.56 Å above and below the Mo plane. This yields a distance between neighboring Mo and S atoms of $d = 2.40$ Å. The angle between the Mo–S bond and the Mo plane is $\theta_0 = 40.6^\circ$. These values are obtained by the DFT calculation discussed below and are consistent with previous DFT calculations [10, 16, 18] and with experimental values [27, 29].

For the purpose of building the tight-binding model, we will follow the notation introduced figure 1. We denote by $t'$ (or $t^+$) and by $b'$ (or $t^-$) the S atoms at the top and bottom layers, respectively. The distance between the two S layers is $d \cos \theta_B = a/\sqrt{3}$. The nearest-neighbour vectors, connecting Mo and S atoms, are given by

$$\mathbf{\delta}_{1z} = d(0, \cos \theta_B, \pm \sin \theta_B),$$

$$\mathbf{\delta}_{2z} = d\left(-\frac{\sqrt{3}}{2} \cos \theta_B, -\frac{1}{2} \cos \theta_B, \pm \sin \theta_B\right),$$

and

$$\mathbf{\delta}_{3z} = d\left(\frac{\sqrt{3}}{2} \cos \theta_B, -\frac{1}{2} \cos \theta_B, \pm \sin \theta_B\right).$$

The MoS$_2$ Brillouin zone is hexagonal. The most important symmetry points and symmetry lines are indicated in figure 2, namely, $\Gamma = (0, 0)$, $K = \left(\frac{2\pi}{3a}, -\frac{2\pi}{3a}\right)$, and $M = \left(\frac{2\pi}{a}, \frac{2\pi}{\sqrt{3}a}\right)$. The reciprocal lattice basis vectors are

$$\mathbf{K}_1 = \frac{4\pi}{\sqrt{3}a} \left(\frac{\sqrt{3}}{2}, -\frac{1}{2}, 0\right)$$

and

$$\mathbf{K}_2 = \frac{4\pi}{\sqrt{3}a} (0, 1, 0).$$

Table 1 summarizes the experimental and theoretical values of the band gap of MoS$_2$. Early photoluminescence experiments [8, 31] had inferred a direct band gap of about 1.9 eV for MoS$_2$. More recently, it has been suggested that this value is actually the result of excitonic states and hence corresponds to the optical gap rather than the actual direct gap between the single-particle VB and CB [32]. Scanning Tunneling Spectroscopy (STS) measurements revealed that the band gap of MoS$_2$ is 2.15 eV [33]. Given the optical gap of about 1.9 eV, the latter value is quite consistent with both theoretical and experimental values of the exciton binding energy, which fall in the range 0.28–0.33 eV according to theory [34, 35] and are either 0.44 eV [36] or 0.22 eV [33] as deduced from experiments. Traditional DFT functionals based on the local density approximation (LDA) and on
the generalized gradient approximation (GGA), not surprisingly, underestimate this band gap [37–39], while the more advanced GW approach tends to overestimate it [32]. The HSE06 functional [22, 23], on the other hand, provides so far the best agreement [40] with the STS result for this gap [33].

In this work, we have therefore chosen the DFT-HSE06 band structure as reference for our fitting procedures. Our DFT-based electronic band structure calculations are carried with the HSE06 functional using the supercell method with a plane-wave basis set (cutoff energy of 500 eV) and the projector-augmented wave (PAW) technique [41, 42], as implemented in the Vienna ab initio Simulation Package (VASP) [43, 44]. We use a supercell consisting of a MoS2 layer with an experimental lattice parameter value of 3.16 Å at its center and a vacuum of 15 Å to minimize the interaction between normal periodical images. The structure is optimized using the GGA approximation with the Perdew-Burke-Ernzerhof (PBE) parametrization [26], between normal periodical images. The structure is optimized at its center and a vacuum of 15 Å to minimize the interaction between normal periodical images. The structure is optimized using the GGA approximation with the Perdew-Burke-Ernzerhof (PBE) parametrization [26], as implemented in the Vienna ab initio Simulation Package (VASP) [43, 44].

Figure 3. The DFT-HSE06 band structure of MoS2 near the gap region. See text for details.

- **Q point**—This point, signaling a local minimum in the CB band along the straight line connecting Γ and K points, has recently received increased attention due to its relevance for transport properties, since the energy minimum \( E_G \) is close to the bottom of the CB [16, 45]. From our DFT-HSE06 calculations, before including SOC, we estimate this energy difference to be \( \Delta E \approx 0.3 \) eV. It is noteworthy that the CB at the Q point moves down in energy in multilayer systems. As discussed in [28], phonon-limited mobility depends quite sensitively on this energy separation. At the Q point, the CB is characterized by a spin splitting of 91 meV and the effective mass has an ellipsoidal shape [16]. The Q point is located close to the mid point between Γ and K points.

- **Γ point**—This point lies close to the top of the valence band. According to our DFT-HSE06 calculations, before including SOC, its energy difference to the K point is very small, namely, \( \Delta E \approx 0.15 \) eV. Hence, in hole-doped samples states both the K and Γ points will contribute to the electronic transport.

The orbital composition is of fundamental importance for building of any tight-binding model. As already found in literature [27], \( d_{xy}, d_{x^2-y^2}, d_{z^2} \) and \( p_{z,\perp} \) are the most important orbitals to describe the valence and the conduction bands. It is worth to stress that \( d_{xy} \) and \( d_{z^2} \) have a dominant contribution at the Γ point, and \( p_{z,\perp} \) gives an important contribution to both Γ and Q points. Thus, for a comprehensive description of the CB and VB along the Brillouin zone, one needs to consider all these orbitals. Tables 2 and 3 show the relative contribution from each orbital at the points Γ and K, as provided by our

---

### Table 1. Summary of experimental and theoretical values of the band gap of MoS2.

| Method                  | Value (eV) | Note                  |
|-------------------------|------------|-----------------------|
| Photoluminescence       | 1.8–1.9    | Optical band gap      |
| Scanning tunneling      | 2.15       |                       |
| spectroscopy (STS)      |            |                       |
| DFT-LDA [38]            | 1.81       |                       |

DFT-HSE06 calculations. These results serve not only to justify the choice of the relevant orbitals of the atomistic model, but also help in finding the right constraints to optimize the tight-binding parameters.

### 3. Model

Let \( \mathbf{r}_i \) denote the Mo atom location in the \( i \)th unit cell. Following Cappelluti and collaborators [27, 28], we consider a tight-binding model with five \( d \) orbitals in the Mo atom, namely,

\[
|\mathbf{r}_i; d_0\rangle = |d_{z^2-r^2}\rangle, \quad |\mathbf{r}_i; d_1\rangle = |d_{x^2-y^2}\rangle,
\]

\[
|\mathbf{r}_i; d_2\rangle = |d_y\rangle, \quad |\mathbf{r}_i; d_3\rangle = |d_{x^2}\rangle, \quad |\mathbf{r}_i; d_4\rangle = |d_{z^2}\rangle,
\]

and six \( p \) orbitals for the S atoms, three for the top \( t \) (+) and three for the bottom \( b \) (−) layers,

\[
|\mathbf{r}_i + \delta_{tz}; p_1\rangle = |p_x^{+}\rangle, \quad |\mathbf{r}_i + \delta_{tz}; p_2\rangle = |p_y^{+}\rangle,
\]

\[
|\mathbf{r}_i + \delta_{tz}; p_3\rangle = |p_z^{+}\rangle.
\]

Starting with this basis we can define on-site energies and hopping amplitudes and write down a tight-binding Hamiltonian. Hereafter we assume that this basis is orthogonal.

The tight-binding Hamiltonian \( \mathcal{H} \) contains Mo–S and S–S nearest-neighbor hopping terms (in the same unit cell), as well as Mo–Mo and S–S next-to-nearest-neighbor ones (in adjacent cells). Each Mo has six S nearest neighbors. while the next-to-nearest neighbor hoppings connect 6 atoms of the same kind, see figure 1. Overall, there is a total of 25 hopping matrix elements inside the unit cell and between the unit cell and the adjacent cells.

The hopping amplitudes are written in terms of Slater–Koster (SK) parameters [21]. We incorporate the \( x \) and \( z \) reflection symmetries in the construction of the basis, when applicable, to reduce the number of terms. We refer to appendix A for a detailed description of the tight-binding Hamiltonian and the transfer integrals. There, we also provide expressions for the hopping amplitudes in terms of the SK integrals \( V_{pd}, V_{dd}, V_{dd}, V_{dd}, V_{pp}, \) and \( V_{pp} \). This allows for a significant reduction in the number of fitting parameters of the model.

To find the energy bands we solve the eigenvector equation that, in the Bloch momentum representation, reads

\[
\mathcal{H}\mathbf{k} = E_{\mathbf{k}}(\mathbf{k})\mathbf{k},
\]

where the eigenstates \( \mathbf{k} \) are expressed in terms of the three-atom basis, namely,

|Band number| Band energy (eV) | \( p_y \) | \( p_z \) | \( p_x \) | \( d_{y^2} \) | \( d_{z^2} \) | \( d_{x^2} \) | \( d_{x^2-y^2} \) |
|---|---|---|---|---|---|---|---|---|
|6| -7.571| 0.252| | | | | | |
|7| -4.105| 0.115| 0.127| 0.309| | | | |
|8| -4.105| 0.127| 0.115| 0.279| | | | |
|9| -3.303| 0.558| | | | | | |
|10| -2.753| 0.099| 0.313| 0.015| | | | |
|11| -2.753| 0.313| 0.009| 0.502| | | | |
|12 VB| -1.262| 0.141| | | | | | |
|13 CB| 2.457| 0.302| 0.045| 0.327| | | | |
|14| 2.457| 0.045| 0.303| 0.048| | | | |
|15| 2.678| 0.083| 0.390| 0.249| | | | |
|16| 2.678| 0.390| 0.083| 0.053| | | | |

Note: Absence of an entry indicates zero contribution.
\[ \mathbf{H}(k) = \sum_{\tau_1} e^{ik \cdot \tau_1} \left[ \sum_{\mu=0}^{4} \alpha_{k,\mu} |r_\mu; d_\mu\rangle + \sum_{\mu=1}^{3} (\beta_{k,\mu} |r_\mu + \delta_{1-}; p_{\mu}\rangle + \gamma_{k,\mu} |r_\mu + \delta_{1+}; p_{\mu}\rangle) \right]. \]  

(9)

For the purpose of implementing the eigenvalue equation we project the vector \( \mathcal{H}(k) \) onto the three-atom basis and write

\[
\begin{pmatrix}
 h^{Mo} + V & T^c & T^b \\
 T^c & h^S + U & S \\
 T^b & S & h^S + U
\end{pmatrix}
\begin{pmatrix}
 \alpha \\
 \tau \\
 \beta
\end{pmatrix} = E
\begin{pmatrix}
 \alpha \\
 \tau \\
 \beta
\end{pmatrix}.
\]

(10)

where have omitted, for the moment, the spin indices. Explicit expressions for the block matrices \( h^{Mo}, h^c, T^c, T^b, S, U, \) and \( V \) are given in appendix A. The matrices \( S, U \) and \( V \) are real and symmetric.

The secular equation (10) is sufficient for a numerical evaluation of the band structure. Nonetheless, it is convenient to use symmetry arguments to reduce the size of the matrices to be diagonalized, allowing us to express analytically the gap and other features of the band structure at \( k \) points of interests.

Let us introduce the symmetric and anti-symmetric components

\[
\begin{align*}
\alpha_{k,\nu} &= \frac{1}{\sqrt{2}} (\gamma_{k,\nu} + \beta_{k,\nu}) \\
\beta_{k,\nu} &= \frac{1}{\sqrt{2}} (\gamma_{k,\nu} - \beta_{k,\nu}),
\end{align*}
\]

(11)

(12)

that allow us to write the Hamiltonian in the matrix form

\[
\begin{pmatrix}
 h^{Mo} & T^c & T^b \\
 T^c & h^S + U & S \\
 T^b & S & h^S + U
\end{pmatrix}
\begin{pmatrix}
 \alpha \\
 \theta \\
 \phi
\end{pmatrix} = E
\begin{pmatrix}
 \alpha \\
 \theta \\
 \phi
\end{pmatrix}.
\]

(13)

The eigenvalue problem can be further simplified by rearranging rows and columns through the transformation \( \psi \rightarrow \bar{\psi} \), where

\[
\psi^T = (\alpha_0, \alpha_1, \alpha_2, \alpha_3, \alpha_4, \theta_1, \theta_2, \theta_3, \phi_1, \phi_2, \phi_3)
\]

(14)

and

\[
\bar{\psi}^T = (\alpha_0, \alpha_1, \alpha_2, \theta_1, \theta_2, \phi_1, \alpha_3, \alpha_4, \phi_1, \phi_2, \theta_3).
\]

(15)

Notice that the first six orbital basis functions are even \( (E) \) with respect to a \( z \)-axis inversion, while the last five are odd \( (O) \). Then, the problem is reduced to two decoupled eigenvalue/eigenvector problems, namely

\[
\begin{pmatrix}
 H^E & 0 \\
 0 & H^O
\end{pmatrix}\psi = E\psi.
\]

(16)

We refer to appendix B for explicit expressions of the matrix elements of \( H^E \) and \( H^O \).

4. Optimization of model parameters

Our tight-binding model Hamiltonian has \( N_p = 12 \) fitting parameters, namely, five on-site orbital energies \( (D_0, D_1, D_2, D_3, D_4) \) and seven Sk parameters related to hopping \( (V_{dd}, V_{dd}, V_{dd}, V_{dd}, V_{dd}, V_{dd}, V_{dd}) \). These parameters are optimized to reproduce the main characteristics of the low-energy bands we obtained from DFT-HSE06 calculations.

Our main goal is to reproduce the energies, orbital composition, and effective masses of the conduction and valance bands at the \( K, Q, \) and \( \Gamma \) points. For that purpose we choose a number of representative \( k \)-points, shown in figure 4, and collect the corresponding band energies \( E_n(k) \), where \( n \) is the band index, to build the data set to be fitted. To better describe the conduction and valance energy bands, we give a larger weight to points \( (k, E_n(k)) \) near the main band gap. In addition, we take a larger concentration of points around \( K, Q, \) and \( \Gamma \) to reproduce the electron effective mass around these high symmetry-points.

We find the optimal tight-binding parameters using the method of least squares. The data set is built from the band energies \( E_j^{DFT} \), where \( j \) labels both the \( k \)-point and band index (see figure 4), with \( j = 1, \cdots, N_p \). The corresponding \( \chi^2 \)-squared function is just a sum of weighted squared residuals, namely,

\[
S(P) = \sum_{j=1}^{N_p} \frac{(E_j^{\text{th}}(P) - E_j^{\text{DFT}})^2}{\sigma_j^2}.
\]

(17)
Table 4. Identification of the tight-binding $2 \times 2$ block structures and their orbital contributions at the $K$ point with the band numbers and their corresponding DFT-HSE06 energies, given in table 3.

| Block structure orbitals | Orbital composition | $(E_+, E_-)$ (eV) | Band numbers |
|-------------------------|--------------------|-------------------|--------------|
| $H_E$: $\alpha_0 - \phi_3$ | $d_{x^2-y^2}, p_x, p_y$ | (1.120, −6.427) | (13CB, 7) |
| $H_E$: $\alpha_2 - \phi_3$ | $d_{x^2-y^2}, d_{xy}, p_x, p_y$ | (−1.111, −5.742) | (12VB, 8) |
| $H_O$: $\alpha_3 - \phi_3$ | $d_{x^2-y^2}, d_{xy}, p_z$ | (3.284, −5.524) | (15, 9) |
| $H_D$: $\alpha_3 - \phi_3$ | $d_{x^2-y^2}, d_{xy}, p_z$ | (2.457, −2.753) | (14, 6) |
| $H_O$: $\phi_3$ | $p_x, p_y$ | (4.899, −3.734) | (16, 11) |
| $H_O$: $\phi_3$ | $d_{x^2-y^2}, p_x, p_y$ | −4.466 | 10 |

Table 5. Identification of the tight-binding $2 \times 2$ block structures and their orbital contributions at the $\Gamma$ point with the band numbers and their corresponding DFT-HSE06 energies, given in table 2.

| Block structure orbitals | Orbital composition | $(E_+, E_-)$ (eV) | Band numbers |
|-------------------------|--------------------|-------------------|--------------|
| $H_E$: $\alpha_0 - \phi_3$ | $d_{x^2-y^2}, p_x, p_y$ | (−1.262, −7.571) | (12VB, 6) |
| $H_E$: $\alpha_2 - \phi_3$ | $d_{x^2-y^2}, p_x, p_y$ | (2.678, −4.105) | (15-16, 7-8) |
| $H_E$: $\alpha_3 - \phi_3$ | $p_x, p_y$ | (2.678, −4.105) | (15-16, 7-8) |
| $H_D$: $\alpha_3 - \phi_3$ | $d_{x^2-y^2}, p_x, p_y$ | (2.457, −2.753) | (13CB-14, 10-11) |
| $H_D$: $\alpha_3 - \phi_3$ | $d_{x^2-y^2}, p_x, p_y$ | (2.457, −2.753) | (13CB-14, 10-11) |
| $H_D$: $\theta_3$ | $p_x, p_y$ | −3.303 | 9 |

Note: In the last column, cases where the bands $n_i$ and $n_j$ have the same energy at the $\Gamma$-point are denoted by $n_i - n_j$.

where $\sigma_j$ is the weight given to the $j$th data set fitting point, $E_j^P(P)$ is the tight-binding energy corresponding to the $j$th data set fitting point. The vector array $P$ of dimension $N_P$ contains the tight-binding parameters to be minimized. We minimize $S$ with respect to $P$ using the Powell method [48], that is an efficient method to find the minimum of a function of several variables without requiring the computation of its derivatives.

Let us briefly describe the route we follow to approximate the low-energy band structure by progressively adding data points.

(i) We compare the results obtained at the $K$ and $\Gamma$ points using the analytical expressions derived in appendix C to the DFT-HSE06 energy values and their orbital compositions.

(ii) We consider $k$ points in the vicinity of $K$ and $\Gamma$. The weights $\sigma$ are adjusted to decrease the importance of these $k$ points as the further away they are from the gap region.

(iii) We consider additional data points to correctly reproduce other features of the CB and VB. In particular, we add $k$ points at and around the $M$ and $Q$ points, to obtain a correct band energy behavior around the main gap over the entire Brillouin zone.

The tight-binding decouples into ‘even’ bands (associated to $H_E$) and ‘odd’ bands (associated to $H_O$). The identification of the parity of the bands at the $K$ and $\Gamma$ points allows us to follow all the bands over the entire Brillouin zone. Notice that around the main energy gap, bands are mostly even (except for the CB at the $\Gamma$ point). Let us now explain how we match DFT-HSE06 band energies with the tight-binding eigenvalues at the $K$ and $\Gamma$-points.

4.1. $K$ point

At the $K$ point, the matrices $H_E$ and $H_O$ in equation (16) can be written in block diagonal form, namely, we can break $H_E$ into three $2 \times 2$ diagonal blocks and $H_O$ into two $2 \times 2$ blocks and one $1 \times 1$ block. The explicit expressions are presented in appendix C.

The inspection of the orbital composition given by the DFT-HSE06 calculations (see table 3) allows us to establish a unique correspondence between pairs of bands and the $2 \times 2$ blocks mentioned above. The correspondence is summarized in table 5.

The identification of the highest $E_+$ (lowest $E_-$) eigenvalue of a given block with the highest (lowest) energy value of the band with corresponding orbital composition and parity severely constrains our model parameters. By applying this methodology to all diagonal blocks, we find analytical expressions for the band energies at the $K$ point, presented in appendix C.

4.2. $\Gamma$ point

At the $\Gamma$ point we can also express the $H$ matrix of equation (16) in block block diagonal form, breaking it into five $2 \times 2$ blocks and one $1 \times 1$ block.

Here we follow the procedure described in the previous subsection, section 4.1. The differences are due to the distinct point-group symmetries of the $K$ and $\Gamma$ points. As a consequence, the orbital compositions of the tight-binding $2 \times 2$ blocks considered in this case are not the same as for the $K$ point. This issue is discussed in appendix C, where we also present the analytical derivation of eigenvalues and eigenstates at the $\Gamma$-point.

7
Table 6. Tight-binding model parameters obtained by optimization using $a = 3.16 \text{ Å}, b_y = 0.710$, and $d = 2.406 \text{ Å}$. 

| Parameters | CB–VB optimization (eV) | VB optimization (eV) |
|------------|-------------------------|---------------------|
| $D_0$      | 0.201                   | 0.191               |
| $D_1$      | $-1.563$                | $-1.599$            |
| $D_2$      | $-0.352$                | 0.081               |
| $D_3$      | $-54.839$               | $-48.934$           |
| $D_4$      | $-39.275$               | $-37.981$           |
| $V_{pdx}$  | 4.196                   | 4.115               |
| $V_{pdy}$  | $-9.880$                | $-8.963$            |
| $V_{pdy}$  | 12.734                  | 10.707              |
| $V_{pdx}$  | $-2.175$                | $-4.084$            |
| $V_{ddx}$  | $-1.153$                | $-1.154$            |
| $V_{ddx}$  | 0.612                   | 0.964               |
| $V_{ddx}$  | 0.086                   | 0.117               |

Note: The second column gives the best parameter set we obtain to fit both the valence (VB) and the conduction (CB) bands, while the third column focuses the optimization on the valence band.

Table 5 presents the identification of the tight-binding symmetry split $2 \times 2$ blocks with their corresponding DFT-HSE06 bands. It is also noteworthy that, as presented in table 2, the *ad initio* calculations show that several band energies coincide at the $\Gamma$ point, namely, 7 and 8, 10 and 11, 13CB and 14, and 15 and 16.

5. Eleven-band model: parameters and results

In this section we present the main results of our study, namely, the tight-binding 11-band parametrization and the corresponding band structure for MoS$_2$. Table 6 presents the best fitting parameters we obtained using the the optimization procedure described in section 4.

Before discussing the results, it worth mentioning that the even-odd parity symmetry of our tight-binding model prevents a perfect match with *ab initio* calculations. For instance, DFT-HSE06 calculations indicate that the CB and VB are mainly ‘even’, but around the $\Gamma$ point they gain a significant odd contribution. Despite this proviso, we show that the tight-binding model reproduces the *ab initio* band structure close Fermi energy with very good accuracy.

Although our tight-binding model contains many adjustable parameters, the optimization procedure presented in the section 4 imposes several implicit constraints. In practise, we find very difficult to obtain a parameter set that reproduces with high accuracy the position of the energy bands, their orbital compositions, and effective masses at the $K$, $\Gamma$, and $Q$ points for both CB and VB. For this reason, in table 6 we present two parameter sets: one that reproduces most features of both VB and CB, but does not yield accurate masses for the VB, and the other that focuses on the VB.

Figure 5 shows the tight-binding band structure calculated with the VB-CB optimized parameter set given in table 6 superposed with the DFT-HSE06 result. We find a very good agreement for the conductance and valence bands energies. The accuracy of the tight-binding results becomes increasingly poorer for band energies further away from the gap region, which is expected given that they were attributed a small weight in the fitting procedure.

For completeness, in table 7 we also include a comparison of the main orbital composition obtained from DFT-HSE06 and the tight-binding result. The orbital compositions at the high symmetry points $\Gamma$, $K$, and $Q$ are not equal to those obtained with the DFT-HSE06, but they show the correct leading $d$ and $p$ orbitals for both CB and VB. We point out that this is not the case in the tight-binding parametrization of [27], where several bands near the main energy gap have incorrect compositions. In particular, at the $K$ point, the correct composition of the VB appears at a high-energy band, far from the gap. In our parametrization, out of the 18 points used in the optimization where analytically expressions where employed, only four yield incorrect compositions and they are located away from the main gap, at low energies.

As shown in table 8, the effective masses are also reasonably well described by the CB–VB parametrization for all three special $k$ points, except for the hole effective mass at the $\Gamma$ point. We try to circumvent this limitation by performing another optimization (named VB) with a heavier weight given to the $k$ values near symmetry points at the VB band. The resulting parametrization describes much more accurately the VB alone, imposing only few distortions on the CB, as figure 6 reveals. This procedure yields
the VB optimization parameters given in table 6 and the orbital compositions and effective masses presented in tables 9 and 8, respectively. Most parameter values are close to those of the global optimization (table 6), while a few differ by more than 25%. The orbital compositions are nearly identical to those obtained in the global optimization. The most striking change is in the hole band mass at the $\Gamma$ point, which becomes essentially identical to the DFT-HSE06 value.

6. Simplified model

The tight-binding model we have developed provides an accurate description of the main features of the CB and VB at the expense of involving a relatively large number of orbitals and fitting parameters. It has already been shown by Liu and coworkers [19] that using just three orbitals for the Mo atom and including only the hopping amplitudes between Mo atoms in plane up to first neighbours is sufficient to open a band gap. With this in mind, we explored whether it is possible to neglect some hopping amplitudes in our tight-binding model and still obtain a reasonable description of the electronic structure near the band gap region. Keeping only the hopping amplitudes between Mo atoms turns out to be insufficient, as it preserves a large amount of degeneracy in the bands. Adding the hopping amplitudes between Mo and neighboring S atoms, without including the hopping amplitudes between S atoms, yields reasonable results. On the other hand, keeping exclusively the Mo–S hoppings does not yield a band gap. In matrix format, this simplified tight-binding model yields the eigenvalue/eigenvector problem

$$
\begin{pmatrix}
th_{Mo} + V + T^{\sigma} + T^{\beta} & \alpha \\
(T^{\gamma}) & \frac{h}{\tau} & \frac{h}{\beta} & E
\end{pmatrix}
\begin{pmatrix}
a \\
\tau \\
\beta \\
E
\end{pmatrix} = 0
$$

(18)

The number of fitting parameters is reduced to from 12 to 10. Symmetries can be fully exploited to break the diagonalization problem into smaller ones, as done previously. After optimization against the DFT-HSE06 band structure, we obtain the values for the fitting parameters listed in

Table 7. Top: contribution from each orbital at the $\Gamma$ point using the CB–VB optimization. Bottom: same but at the $K$ point.

| Band number (\Gamma point) | $p_y$ | $p_x$ | $p_z$ | $d_{yz}$ | $d_{xz}$ | $d_{z^2}$ |
|---------------------------|------|------|------|--------|--------|---------|
| DFT-HSE06 12 VB           | 0.141| 0.045| 0.327| 0.596  |        |         |
| DFT-HSE06 13 CB           | 0.302| 1.4 $\cdot 10^{-2}$ | 0.049 |         |         |
| t-b 12 VB                 | 0.11 | 6.6 $\cdot 10^{-6}$ | 0.889 | 5.4 $\cdot 10^{-5}$ |
| t-b 13 CB                 |      |      |      |        |        |         |

Table 8. Effective masses (in units of the free electron mass) at the $\Gamma$ and $K$ points resulting from the CB–VB and the VB optimization.

| HSE06 | CB–VB | VB |
|-------|-------|----|
| $\Gamma$ point $m_e$ | 0.76 | 0.35 |
| $\Gamma$ point $m_h$ | -2.47 | -0.62 | -2.47 |
| $K$ point $m_e$ | 0.42 | 0.58 |
| $K$ point $m_h$ | -0.47 | -0.61 | -0.62 |
| $Q$ point $m_e$ | 0.59 | 0.59 |

Note: Omitted orbitals have negligible or null contribution. t-b stands for tight-binding model.
The resulting band structure is shown in figure 7 superposed with the DFT-HSE06 band structure. We note that we were able to reproduce quite well the the entire VB, while the CB is well reproduced just around the $K$ point, missing the correct behaviour around the $Q$ and $\Gamma$ points. Therefore, the simplified model is somewhat limited in its applicability. It is suitable for the hole-doped region when the Fermi energy is brought to the top of the VB. It also provides a good description of the system when there is weak electron doping.

### 7. The effect of spin–orbit interaction

Due to the broken lattice inversion symmetry, strong spin–orbit interactions split the spin-degenerate valence bands in MoS$_2$ monolayers as well as in other group VI dichalcogenides. The spin–orbit coupling in this case is due to the Dresselhaus mechanism. Interestingly, the spin splitting in inequivalent valleys must be opposite, as imposed by time-reversal symmetry. As mentioned in section 1, these features open interesting possibilities for the control of spins and valleys in these 2D materials [3–5, 7].

Let us focus on the large spin-splitting at the $K$ point of the VB. Its origin is qualitatively well understood: the valence band states are mostly made of $d_{xy}$ and $d_{x^2-y^2}$ orbitals with $l = 2$ and $m = \pm 2$. Therefore, the $L^z_{\text{Mo}}S^z_{\text{Mo}}$ component of the SOC naturally gives a valley-dependent splitting of the bands. In contrast, the dominant contribution of the CB lowest energy state comes from the $d_z^2$ orbital with $l = 2$ and $m = 0$, which cancels the spin–orbit splitting. These arguments agree with the quantitative analysis presented in [46].

A complete tight-binding model that accounts for the effect of SOC over the entire Brillouin zone, including explicitly the $p$-orbitals of the chalcogen atoms, and taking into account the correct orbital composition of the main bands, is lacking.

In this section, we present an extension of our tight-binding model that includes the effect of an atomic spin–orbit coupling on all the atoms. For that purpose, we follow the formulation presented in [28]. Our starting point is the 11-band tight-binding spinless model derived earlier, with the Hamiltonian expressed in the appropriate symmetrized form, namely, where the block Hamiltonians $H_E$ and $H_O$ appear explicitly. The spin–orbit coupling term is inserted in the Hamiltonian by means of a pure intra-atomic spin–orbit interaction acting on all the atoms, explicitly given by

$$H_{\text{SO}} = \sum_a \frac{\lambda_a}{\hbar} L_a \cdot S_a,$$

(19)

where $\lambda_a$ is the intrinsic effective SOC constant for an $a$ atom (Mo or S), $L_a$ is the atomic orbital angular momentum operator, and $S_a$ is the electronic spin operator. Hence,
A better result is obtained by adopting the SOC parameters of Cappelluti et al [28], namely, $\lambda_{\text{Mo}} = 75$ meV and $\lambda_z = 0.52$ meV. Inserting these values into our tight-binding formulation results instead in $\Delta^V = 151$ meV, which is in good agreement with the experimental value. Thus we present in figure 8 our results for the spin-resolved band structure based on this choice of SOC parameters.

8. Conclusions

In conclusion, in this paper we provide a suitable and straightforward tight-binding model for monolayer dichalcogenides, focusing our attention on MoS$_2$. We show that this model reproduces rather well the structure near the main energy gap provided by an accurate DFT band structure calculation based on the HSE06 functional. It also reproduces the correct orbital composition of the bands. A fundamental ingredient in obtaining this result is the use of an optimization process that makes use of analytical expressions of the energy bands at symmetry points. In constructing of our model we exploited the decoupling that exists between even and odd bands upon $z$ inversion. Around the main gap, the bands are primarily even. Overall, the model yields 11 bands in the absence of spin–orbit coupling and involves 12 fitting parameters. We provide two parametrizations for this case: one that is suitable for both conduction and valence bands (but less accurate for the valence band), and another that gives a very accurate description of important features of the valence band, such as the effective mass. When spin–orbit coupling is added, the number of fitting parameters jumps to 14. Our choice of parameters in this case yields a spin splitting of the valence band in good agreement with experimental values.

We also investigate the possibility of turning off some hopping amplitudes in our model to reduce the number of parameters to 10 in the absence of spin–orbit coupling. The simplified model is suitable for describing the hole-doped region or when one is only interested in the region around the $K$ point.

It is important to note that our tight-binding model parameters were based on a DFT calculation of a fully relaxed lattice structure. Experimental [11, 12] and theoretical [10, 50] studies show that the electronic structure of monolayer dichalcogenides can show significative changes under an applied strain. Strain in the context of the DFT calculations implies forcing a different lattice constant and/or lattice deformations. In principle, one could follow the changes in the band structure as a function of the strain and then use those changes to obtain tight-binding parameters for a range of bond deformations. Developing a formulation that could take into account the effect of strain would be an important contribution, but beyond the scope of this work.

In summary, the present work provides a sound starting point for any further investigation of electronic transport properties of single-layer semiconductor transition-metal dichalcogenides, or any other investigation that relies heavily on an accurate energy level positioning and wave function composition.

Appendix A. Tight-binding model and Slater–Koster parameters

The tight-binding model is defined by the following second-quantized Hamiltonian (spin indices have been omitted):

\[
\mathcal{H} = \sum_{\mathbf{r}} \sum_{\mu} E^\text{Mo}_\mu d^\dagger_\mu d_\mu + \sum_{\mathbf{r}} \sum_{\mu, \nu} \epsilon_{\mu, \nu} \left[ \left( \frac{d^\dagger_{\mu, \nu}}{p^b_{\mu, \nu}} \right) p^b_{\mu, \nu} + \left( \frac{d^\dagger_{\nu, \mu}}{p^b_{\nu, \mu}} \right) p^b_{\nu, \mu} \right] + \sum_{\mathbf{r}, \mathbf{r}'} \sum_{\mu, \nu} t_{\mu, \nu}^b d^\dagger_{\mu, \nu} p^b_{\mu, \nu} + t_{\mu, \nu}^b d^\dagger_{\mu, \nu} p^b_{\mu, \nu} + \text{H.c.} + \sum_{\mathbf{r}, \mathbf{r}'} \sum_{\mu, \nu} t_{\mu, \nu}^b d^\dagger_{\mu, \nu} p^b_{\mu, \nu} + t_{\mu, \nu}^b d^\dagger_{\mu, \nu} p^b_{\mu, \nu} + \text{H.c.} + \sum_{\mathbf{r}, \mathbf{r}'} \sum_{\mu, \nu} \left[ s_{\mu, \nu} \left( \frac{p^b_{\mu, \nu}}{p^b_{\mu, \nu}} \right) + \text{H.c.} \right] + \sum_{\mathbf{r}, \mathbf{r}'} \sum_{\mu, \nu} v_{\mu, \nu} d^\dagger_{\mu, \nu} d_{\mu, \nu} + \text{H.c.} + \sum_{\mathbf{r}, \mathbf{r}'} \sum_{\mu, \nu} \left[ u_{\mu, \nu} \left( \frac{p^b_{\mu, \nu}}{p^b_{\mu, \nu}} \right) + \text{H.c.} \right],
\]

where \((ij)\) denotes a sum over pairs of nearest-neighbour cells. The operators \(d_{\mu, \nu}(d^\dagger_{\mu, \nu})\) annihilate (create) an electron on the Mo in the unit cell \(i\) and orbital \(\mu\). Similarly, the operators \(p^b_{\mu, \nu}(d^\dagger_{\mu, \nu})\) annihilate (create) electrons at the bottom \(b\) and top \(t\) S sites of the unit cell \(i\), respectively. We assume that the top and bottom S layers are symmetric (\(z\) inversion symmetry).

We use the basis set defined in section 3 to express the on-site energies and the hopping integrals. The on-site energies are given by

\[
\epsilon^\text{Mo}_{\mu} = \langle \mathbf{r}; d^\dagger_{\mu} \mathcal{H} | \mathbf{r}; d_{\mu} \rangle
\]

and

\[
\epsilon^S_{\mu} = \langle \mathbf{r}; d^\dagger_{\mu} \mathcal{H} | \mathbf{r} + \delta_{1z}; p_{\mu} \rangle.
\]

The hopping matrix elements between Mo and S orbitals are

\[
t^b_{\mu, \nu} = \langle \mathbf{r}; d^\dagger_{\mu} \mathcal{H} | \mathbf{r} + \delta_{1z}; p_{\nu} \rangle, \quad t^b_{\mu, \nu} = \langle \mathbf{r}; d^\dagger_{\mu} \mathcal{H} | \mathbf{r} + \delta_{1z}; p_{\nu} \rangle, \quad t^b_{\mu, \nu} = \langle \mathbf{r}; d^\dagger_{\mu} \mathcal{H} | \mathbf{r} + \delta_{1z}; p_{\nu} \rangle, \quad t^b_{\mu, \nu} = \langle \mathbf{r}; d^\dagger_{\mu} \mathcal{H} | \mathbf{r} - \delta_{1z}; p_{\nu} \rangle.
\]

The hopping matrix elements between top and bottom S orbitals read

\[
s_{\mu, \nu} = \langle \mathbf{r} + \delta_{1z}; p_{\mu} | \mathcal{H} | \mathbf{r} + \delta_{1z}; p_{\nu} \rangle.
\]

while the nearest-neighbor Mo–Mo hopping integrals are

\[
v^E_{\mu, \nu} = \langle \mathbf{r}; d^\dagger_{\mu} \mathcal{H} | \mathbf{r} + \mathbf{R}_1; d_{\mu} \rangle, \quad v^N_{\mu, \nu} = \langle \mathbf{r}; d^\dagger_{\mu} \mathcal{H} | \mathbf{r} + \mathbf{R}_2; d_{\mu} \rangle, \quad v^{NW}_{\mu, \nu} = \langle \mathbf{r}; d^\dagger_{\mu} \mathcal{H} | \mathbf{r} + \mathbf{R}_3; d_{\mu} \rangle, \quad v^{SW}_{\mu, \nu} = \langle \mathbf{r}; d^\dagger_{\mu} \mathcal{H} | \mathbf{r} + \mathbf{R}_4; d_{\mu} \rangle.
\]

and the S–S next-nearest-neighbor hopping matrix elements read

\[
u^{F}_{\mu, \nu} = \langle \mathbf{r}; d^\dagger_{\mu} \mathcal{H} | \mathbf{r} + \mathbf{R}_1; d_{\mu} \rangle, \quad v^{NE}_{\mu, \nu} = \langle \mathbf{r}; d^\dagger_{\mu} \mathcal{H} | \mathbf{r} + \mathbf{R}_2; d_{\mu} \rangle, \quad v^{NW}_{\mu, \nu} = \langle \mathbf{r}; d^\dagger_{\mu} \mathcal{H} | \mathbf{r} + \mathbf{R}_3; d_{\mu} \rangle, \quad v^{SW}_{\mu, \nu} = \langle \mathbf{r}; d^\dagger_{\mu} \mathcal{H} | \mathbf{r} + \mathbf{R}_4; d_{\mu} \rangle.
\]

Notice that \(\mathcal{H}\) contains Mo–S and S–S nearest-neighbour (same unit cell) hopping amplitudes and Mo–Mo and S–S next-to-nearest-neighbour hopping amplitudes (adjacent cells). For the latter, each Mo and each S has six next-to-nearest neighbours. Overall, there is a total of 25 hopping amplitudes within the unit cell and between the unit cell and the adjacent cells. The hopping amplitudes are indicated in figure A1.

The following associations are made for the on-site energies of Mo atoms: 

\[
\epsilon^1_{\text{Mo}} \equiv \Delta_0, \quad \epsilon^2_{\text{Mo}} \equiv \Delta_2, \quad \epsilon^3_{\text{Mo}} \equiv \Delta_4.
\]

For on-site energies of the S atoms we define \(\epsilon^1_S \equiv \Delta_0\) and \(\epsilon^2_S \equiv \Delta_2\).

The hopping amplitudes can be written in terms of SK integrals. We can also incorporate the \(x\) and \(z\) reflection symmetries, when applicable, to reduce the number of terms. Here we provide expressions for the more relevant hopping amplitudes...
in terms of seven SK integrals. This allows us to substantially reduce the number of fitting parameters of the model. Below we list amplitudes that are not identically zero.

- Mo–S (Here we present the expressions for the $t^i$ hopping matrix elements. The $t^f$ ones follow similar expressions, with $\theta_b \leftrightarrow -\theta_b$.)

\[
t^i_{03} = \sin \theta_b \left( \sin^2 \theta_b - \frac{1}{2} \cos^2 \theta_b \right) V_{pde} + \sqrt{3} \sin \theta_b \cos^2 \theta_b V_{pdx},
\]

(A.33)

\[
t^i_{11} = -\frac{3}{8} \cos^3 \theta_b V_{pde} - \frac{\sqrt{3}}{2} \cos \theta_b \left( 1 - \frac{1}{2} \cos^2 \theta_b \right) V_{pdx},
\]

(A.34)

\[
t^i_{02} = \cos \theta_b \left( \sin^2 \theta_b - \frac{1}{2} \cos^2 \theta_b \right) V_{pde} - \sqrt{3} \cos \theta_b \sin \theta_b V_{pdx},
\]

(A.23)

\[
t^i_{12} = -\frac{\sqrt{3}}{8} \cos^3 \theta_b V_{pde} + \frac{1}{2} \cos \theta_b \left( 1 + \frac{1}{2} \cos^2 \theta_b \right) V_{pdx},
\]

(A.35)

\[
t^i_{03} = \sin \theta_b \left( \sin^2 \theta_b - \frac{1}{2} \cos^2 \theta_b \right) V_{pde} + \sqrt{3} \sin \theta_b \cos^2 \theta_b V_{pdx},
\]

(A.24)

\[
t^i_{13} = \frac{1}{2} \sin \theta_b \cos^2 \theta_b \left( \frac{\sqrt{3}}{2} V_{pde} - V_{pdx} \right),
\]

\]

(A.37)

\[
t^i_{21} = \frac{1}{2} \cos \theta_b V_{pde},
\]

(A.26)

\[
t^i_{22} = -\frac{3}{8} \cos^3 \theta_b V_{pde} - \frac{\sqrt{3}}{2} \cos \theta_b \left( 1 - \frac{1}{2} \cos^2 \theta_b \right) V_{pdx},
\]

(A.38)

\[
t^i_{21} = \frac{\sqrt{3}}{4} \sin \theta_b \cos^2 \theta_b \left( \frac{\sqrt{3}}{4} V_{pde} - 2 V_{pdx} \right),
\]

(A.39)

\[
t^i_{31} = \frac{1}{4} \cos \theta_b V_{pde} + \sin \theta_b V_{pdx} + \sin \theta_b (1 - 2 \cos^2 \theta_b) V_{pdx},
\]

(A.27)

\[
t^i_{31} = \frac{3}{4} \cos \theta_b \sin \theta_b V_{pde} + \frac{1}{2} \cos \theta_b \sin \theta_b V_{pdx},
\]

(A.40)

\[
t^i_{43} = \frac{3}{4} \sin \theta_b \cos \theta_b \left( \frac{\sqrt{3}}{4} V_{pde} - 2 V_{pdx} \right),
\]

(A.41)

\[
t^i_{43} = \frac{3}{2} \cos \theta_b \sin \theta_b V_{pde} + \frac{\sqrt{3}}{2} \cos \theta_b (1 - 2 \sin^2 \theta_b) V_{pdx},
\]

(A.30)

\[
t^i_{52} = -\frac{3}{4} \sin \theta_b \cos \theta_b \left( \frac{\sqrt{3}}{4} V_{pde} - 2 V_{pdx} \right),
\]

(A.42)

\[
t^i_{52} = \frac{3}{4} \sin \theta_b \cos \theta_b \left( \frac{\sqrt{3}}{4} V_{pde} - 2 V_{pdx} \right),
\]

(A.43)

\[
t^i_{41} = \frac{3}{4} \cos \theta_b \sin \theta_b V_{pde} + \sin \theta_b \left( 1 - \frac{1}{2} \cos^2 \theta_b \right) V_{pdx},
\]

(A.31)

\[
t^i_{41} = \frac{3}{4} \cos \theta_b \sin \theta_b V_{pde} + \sin \theta_b \left( 1 - \frac{1}{2} \cos^2 \theta_b \right) V_{pdx},
\]

(A.44)
\[ i'_{13} = -\frac{\sqrt{3}}{2} \sin^2 \theta_b \cos \theta_b V_{pd} - \frac{1}{2} \cos \theta_b (1 - 2 \sin^2 \theta_b) V_{pd}. \]  
\hspace{1cm} (A.45)

\[ s_{22} = V_{ppw}, \]  
\hspace{1cm} (A.60)

\[ s_{33} = V_{ppw}, \]  
\hspace{1cm} (A.61)

A general yet compact expression for all amplitudes is given by the matrices

\[ t^b = \begin{pmatrix} 0 & t'_{02} & -t'_{03} \\ 0 & t'_{12} & -t'_{13} \\ t'_{21} & 0 & 0 \end{pmatrix}, \]  
\hspace{1cm} (A.63)

\[ t^{1b} = \begin{pmatrix} t_{01} & t_{02} & -t_{03} \\ t_{11} & t_{12} & -t_{13} \\ t_{21} & t_{22} & t_{23} \end{pmatrix}, \]  
\hspace{1cm} (A.64)

\[ t^{l,b} = \begin{pmatrix} -t_{01} & -t_{02} & -t_{03} \\ -t_{11} & -t_{12} & -t_{13} \\ -t_{21} & -t_{22} & t_{23} \end{pmatrix}, \]  
\hspace{1cm} (A.65)

\[ t^{r,b} = \begin{pmatrix} -t_{01} & -t_{02} & -t_{03} \\ -t_{11} & -t_{12} & -t_{13} \\ t_{21} & t_{22} & t_{23} \end{pmatrix}, \]  
\hspace{1cm} (A.66)

\[ v^E = \begin{pmatrix} \bar{v}_{00} & v_{01}^E & 0 & 0 \\ v_{01}^E & \bar{v}_{11} & 0 & 0 \\ 0 & 0 & \bar{v}_{22}^E & 0 \\ 0 & 0 & 0 & \bar{v}_{33}^E \end{pmatrix}, \]  
\hspace{1cm} (A.68)

\[ v^{W} = \begin{pmatrix} \bar{v}_{00} & v_{01}^{W} & 0 & 0 \\ v_{01}^{W} & \bar{v}_{11} & 0 & 0 \\ 0 & 0 & \bar{v}_{22}^{W} & 0 \\ 0 & 0 & 0 & \bar{v}_{33}^{W} \end{pmatrix}, \]  
\hspace{1cm} (A.69)
where the Bloch vector is given by

\begin{equation}
\mathbf{v}^{NE} = \begin{pmatrix}
\frac{1}{2}v_0^E & -\frac{1}{2}v_0^E & v_0^NE \\
-\frac{1}{2}v_0^E & \frac{1}{2}v_1^E + \frac{3}{4}v_2^E & v_1^NE \\
v_0^NE & v_1^NE & \frac{1}{2}v_2^E + \frac{3}{4}v_1^E \\
0 & 0 & 0 \\
\end{pmatrix},
\end{equation}

(\text{A.70})

\begin{equation}
\mathbf{v}^{NW} = \begin{pmatrix}
\frac{1}{2}v_0^E & -\frac{1}{2}v_0^E & -v_0^NE \\
-\frac{1}{2}v_0^E & \frac{1}{2}v_1^E + \frac{3}{4}v_2^E & -v_1^NE \\
-v_0^NE & -v_1^NE & \frac{1}{2}v_2^E + \frac{3}{4}v_1^E \\
0 & 0 & 0 \\
\end{pmatrix},
\end{equation}

(\text{A.71})

\begin{equation}
u^E = \begin{pmatrix}
u_1^E & 0 & 0 \\
0 & \nu_2^E & 0 \\
0 & 0 & \nu_3^E \\
\end{pmatrix},
\end{equation}

(A.72)

Resorting to the orthogonal basis, we can rewrite the eigenvalue/eigenvector problem as a system of linear coupled equations,

\begin{equation}
[E(k) - \varepsilon_{\mu}^{Mo}]\mathbf{a}_{\nu\mu} = \sum_{\nu} \left\{ (r_{\nu\mu}^{vb} + z_{\nu\mu}^{vb} - z_{\nu\mu}^{vb})\mathbf{a}_{\nu\mu} + (t_{\nu\mu}^{vb} + z_{\nu\mu}^{vb} - \sum_{\gamma} z_{\nu\gamma}^{vb}t_{\nu\gamma}^{vb})\mathbf{b}_{\nu\mu}\right\} + 2\sum_{\nu} \left\{ (c_{\nu\mu}^{vb} + c_{\nu\mu}^{vb})\mathbf{a}_{\nu\mu} + c_{\nu\mu}^{vb}\mathbf{b}_{\nu\mu}\right\}.
\end{equation}

(B.3)

\begin{equation}
[E(k) - \varepsilon_{\mu}^{Me}]\mathbf{b}_{\nu\mu} = \sum_{\nu} \left\{ (r_{\nu\mu}^{vb} + z_{\nu\mu}^{vb} - z_{\nu\mu}^{vb})\mathbf{a}_{\nu\mu} + \sum_{\nu} \left\{ (c_{\nu\mu}^{vb} + c_{\nu\mu}^{vb})\mathbf{a}_{\nu\mu} + c_{\nu\mu}^{vb}\mathbf{b}_{\nu\mu}\right\}.
\end{equation}

(B.4)

and

\begin{equation}
[E(k) - \varepsilon_{\mu}^{Ne}]\mathbf{a}_{\nu\mu} = \sum_{\nu} \left\{ (r_{\nu\mu}^{vb} + z_{\nu\mu}^{vb} - z_{\nu\mu}^{vb})\mathbf{a}_{\nu\mu} + \sum_{\nu} \left\{ (c_{\nu\mu}^{vb} + c_{\nu\mu}^{vb})\mathbf{a}_{\nu\mu} + c_{\nu\mu}^{vb}\mathbf{b}_{\nu\mu}\right\}.
\end{equation}

(B.5)

and

\begin{equation}
[E(k) - \varepsilon_{\mu}^{Ne}]\mathbf{b}_{\nu\mu} = \sum_{\nu} \left\{ (r_{\nu\mu}^{vb} + z_{\nu\mu}^{vb} - z_{\nu\mu}^{vb})\mathbf{a}_{\nu\mu} + \sum_{\nu} \left\{ (c_{\nu\mu}^{vb} + c_{\nu\mu}^{vb})\mathbf{a}_{\nu\mu} + c_{\nu\mu}^{vb}\mathbf{b}_{\nu\mu}\right\}.
\end{equation}

(B.6)

and

\begin{equation}
[E(k) - \varepsilon_{\mu}^{Ne}]\mathbf{a}_{\nu\mu} = \sum_{\nu} \left\{ (r_{\nu\mu}^{vb} + z_{\nu\mu}^{vb} - z_{\nu\mu}^{vb})\mathbf{a}_{\nu\mu} + \sum_{\nu} \left\{ (c_{\nu\mu}^{vb} + c_{\nu\mu}^{vb})\mathbf{a}_{\nu\mu} + c_{\nu\mu}^{vb}\mathbf{b}_{\nu\mu}\right\}.
\end{equation}

Appendix B. Tight-binding energy bands

To find the energy bands we need to solve the the eigenvalue/eigenvector problem in the Bloch momentum representation,

\[ \mathcal{H}^{\text{B}}[\mathbf{k}] = E(k)[\mathbf{k}], \]

(B.1)

where the Bloch vector is given by

\[ \mathbf{k} = \sum_{\mathbf{k}} e^{i\mathbf{k} \cdot \mathbf{r}} \left[ \sum_{\mu=0}^{3} \alpha_{\mathbf{k},\mu} r_{\mu} + \sum_{\mu=1}^{3} (\beta_{\mathbf{k},\mu} r_{\mu} + \delta_{\mathbf{k},\mu} \hat{\mathbf{p}}_{\mu}) + \mathbf{a}_{\mathbf{k}} \right]. \]

(B.2)

where \( z_1 = e^{i\mathbf{k} \cdot \mathbf{R}_1} e^{i\mathbf{k} \cdot \mathbf{R}_2} = e^{i\mathbf{k} \cdot \mathbf{R}_1} / 2 e^{i\mathbf{k} \cdot \mathbf{R}_2} / 2 \), \( z_2 = e^{i\mathbf{k} \cdot \mathbf{R}_3} = e^{i\mathbf{k} \cdot \mathbf{R}_1} / 2 e^{i\mathbf{k} \cdot \mathbf{R}_2} / 2 \), \( z_3 = e^{i\mathbf{k} \cdot \mathbf{R}_3} = e^{i\mathbf{k} \cdot \mathbf{R}_1} / 2 e^{i\mathbf{k} \cdot \mathbf{R}_2} / 2 \).

(B.6-7)
and
\[ c_{12} \equiv \frac{z_1 z_2 + z_1^* z_2^*}{2} = \cos(k \cdot R_i - k \cdot R_j) \]
\[ = \cos\left(k_x a/2 - k_y \sqrt{3} a/2\right). \]  
(B.8)

In matrix form, we have
\[
\begin{pmatrix}
    h^{Mo} + V & T^E & T^O \\
    (T^E)^T & h^S + U & s \\
    (T^O)^T & s & h^S + U
\end{pmatrix}
\begin{pmatrix}
    \alpha \\
    \tau \\
    \beta
\end{pmatrix}
= E
\begin{pmatrix}
    \alpha \\
    \tau \\
    \beta
\end{pmatrix},
\]
(B.9)

where
\[
h^{Mo} = \begin{pmatrix}
    \Delta_0 & 0 & 0 & 0 \\
    0 & \Delta_2 & 0 & 0 \\
    0 & 0 & \Delta_3 & 0 \\
    0 & 0 & 0 & \Delta_4
\end{pmatrix},
\]
(B.10)
\[
h^S = \begin{pmatrix}
    \Delta_p & 0 & 0 \\
    0 & \Delta_p & 0 \\
    0 & 0 & \Delta_s
\end{pmatrix},
\]
(B.11)
\[
T^E = t^E + z_2(t^{1,E} + z_1 t^{2,E}),
\]
(B.12)
\[
T^b = t^b + z_2(t^{1,b} + z_1 t^{2,b}),
\]
(B.13)
\[
V = 2(c_1 v^E + c_2 v^{NE} + c_{12} v^{NW}),
\]
(B.14)
\[
U = 2(c_1 u^E + c_2 u^{NE} + c_{12} u^{NW}).
\]
(B.15)

This formulation suffices for a numerical evaluation of the bands. However, in order to obtain an analytical expression for the gap and other features of the band structure at the symmetry points, it is necessary to reduce the size of the matrices to be diagonalized. This can be done by exploring underlying symmetries in the equations.

Let us define the symmetric and anti-symmetric components
\[
\theta_{k,v} = \frac{1}{\sqrt{2}} (\kappa_{k,v} + \beta_{k,v}),
\]
(B.16)
\[
\phi_{k,v} = \frac{1}{\sqrt{2}} (\kappa_{k,v} - \beta_{k,v}).
\]
(B.17)

In terms of these components, the eigenproblem takes the form
\[
\begin{pmatrix}
    h^{Mo} + V & T^E & T^O \\
    (T^E)^T & h^S + U & s \\
    (T^O)^T & s & h^S + U - s
\end{pmatrix}
\begin{pmatrix}
    \alpha \\
    \theta \\
    \phi
\end{pmatrix}
= E
\begin{pmatrix}
    \alpha \\
    \theta \\
    \phi
\end{pmatrix},
\]
(B.18)

where we introduced new hopping matrices
\[
T^E = \frac{1}{\sqrt{2}} (T^E + T^b)
\]
(B.19)
\[
T^O = \frac{1}{\sqrt{2}} (T^E - T^b).
\]
(B.20)

We can further simplify the eigenproblem by rearranging amplitudes in the eigenvector, going from
\[
\psi^T = (a_0, a_1, a_2, a_3, a_4, \theta_1, \theta_2, \theta_3, \phi_1, \phi_2, \phi_3).
\]
(B.21)
to
\[
\tilde{\psi}^T = (a_0, a_1, a_2, \theta_1, \theta_2, \phi_1, a_3, a_4, \phi_2, \phi_3).
\]
(B.22)

This amounts to ordering the basis states such that the first six components in the eigenvector are even \((E)\) while the last five are odd \((O)\) with respect to \(z\) inversion. As a result, the eigenproblem can be recast in the decoupled form
\[
\begin{pmatrix}
    H^E & 0 \\
    0 & H^O
\end{pmatrix}\tilde{\psi} = E\tilde{\psi},
\]
(B.23)

where
\[
H^E = \left( \frac{h^{Mo,E} + T^{E,O}}{T^{E,O}} \right),
\]
(B.24)
\[
H^O = \left( \frac{h^{Mo,O} + T^{O,E}}{T^{O,E}} \right),
\]
(B.25)

We have introduced the following matrices:
\[
h^{Mo,E} = \begin{pmatrix}
    \Delta_0 & 0 & 0 \\
    0 & \Delta_2 & 0 \\
    0 & 0 & \Delta_3
\end{pmatrix} + V^E,
\]
(B.26)
\[
h^{Mo,O} = \begin{pmatrix}
    \Delta_0 & 0 \\
    0 & \Delta_2 & 0 \\
    0 & 0 & \Delta_3
\end{pmatrix} + V^O,
\]
(B.27)
\[
h^{S,O} = \begin{pmatrix}
    \Delta_p & 0 \\
    0 & \Delta_p & 0 \\
    0 & 0 & \Delta_s
\end{pmatrix} + U^{E,O} + S^O,
\]
(B.28)
\[
h^{S,E} = \begin{pmatrix}
    \Delta_p & 0 \\
    0 & \Delta_p & 0 \\
    0 & 0 & \Delta_s
\end{pmatrix} + U^{E,O} + S^E,
\]
(B.29)
\[
U^{E,O} = U,
\]
(B.30)
\[
T^{E,O} = \begin{pmatrix}
    T_{01}^E & T_{02}^E & T_{03}^O \\
    T_{11}^E & T_{12}^E & T_{13}^O \\
    T_{21}^E & T_{22}^E & T_{23}^O
\end{pmatrix}.
\]
(B.31)
Then, $V^E = \begin{pmatrix} V_{00} & V_{01} & V_{02} \\ V_{01} & V_{11} & V_{12} \\ V_{02} & V_{12} & V_{22} \end{pmatrix}$, (B.33)
\[ V^O = \begin{pmatrix} V_{33} & V_{34} \\ V_{34} & V_{44} \end{pmatrix}, \] (B.34)
\[ U^{E,O} = \begin{pmatrix} U_{11} & U_{12} & 0 \\ U_{12} & U_{22} & 0 \\ 0 & 0 & U_{33} \end{pmatrix}, \] (B.35)
\[ S^O = \begin{pmatrix} -s_{11} & 0 & 0 \\ 0 & -s_{22} & 0 \\ 0 & 0 & s_{33} \end{pmatrix}, \] (B.36)
\[ S^E = \begin{pmatrix} s_{11} & 0 & 0 \\ 0 & s_{22} & 0 \\ 0 & 0 & -s_{33} \end{pmatrix}, \] (B.37)
\[ t_{02} + 2 t_{03}^I = t_{13}' + 2 t_{13}^I = t_{43} + 2 t_{43}^I = 0 \] due to the SK decomposition. We can break $H^E$ into three $2 \times 2$ diagonal blocks and $H^O$ into two $2 \times 2$ blocks and one $1 \times 1$ block. All blocks can then be diagonalized analytically. Explicitly,
\[ \alpha_0 = \phi_3 \]
\[ \alpha_1 - \theta_2 \]
\[ \alpha_2 - \theta_1 \]
\[ \alpha_3 - \phi_1 \]
\[ \alpha_4 - \phi_2 \]
\[ \theta_3 \]
\[ \Delta_2 + 3(v_{11}^E + v_{22}^E) \]
\[ \Delta_6 + 6 u_{33}^S - s_{33} \]

**Appendix C. Expansion around symmetry points**

Expanding the hopping matrix elements around symmetry points in the Brillouin zone allows to obtain analytical expressions for bands energies and orbital composition.

**C.1. $\Gamma$ point**

At the $\Gamma$ point, $k_x = k_y = 0$, resulting in $z_1 = z_2 = 1$ and $c_1 = c_2 = c_{12} = 1$. Then,
\[ T^{E,O}_\Gamma = \sqrt{2} \begin{pmatrix} 0 & 0 & t_{03}^I + 2 t_{03}^I \\ 0 & t_{12}^I + t_{12}^I & 0 \\ t_{12}^I + t_{21}^I & 0 & 0 \end{pmatrix}, \] (C.1)
\[ T^{O,E}_\Gamma = \sqrt{2} \begin{pmatrix} t_{31}^I + 2 t_{32}^I & 0 & 0 \\ 0 & t_{42}^I + 2 t_{42}^I & 0 \\ 0 & 0 & 0 \end{pmatrix}, \] (C.2)
\[ V^{E}_\Gamma = 2 \begin{pmatrix} 3 v_{00}^E & 0 & 0 \\ 0 & 3(v_{11}^E + v_{22}^E) & 0 \\ 0 & 0 & 3(v_{11}^E + v_{22}^E) \end{pmatrix}, \] (C.3)
\[ V^{O}_\Gamma = \frac{3}{2} \begin{pmatrix} v_{33}^E + v_{44}^E & 0 \\ 0 & v_{33}^E + v_{44}^E \end{pmatrix}, \] (C.4)

The bands can be identified by matching their composition to the results of the DFT-HSE06 calculations, (see table 2). For instance, the valence band state at the $\Gamma$ point
is mostly composed by $d_z$ and $p_z$-orbitals. Another band state (band number 6, as defined in table 2) that has a similar orbital composition is lower in energy than the valence band state. Therefore, we associate the highest eigenvalue of (C.8) to the valence band energy, while the lowest eigenvalue is put in correspondence with the band number 6 energy. As a result, we find

$$E_{\text{valence}}(\Gamma) = \frac{\Delta_0 + 61_{00}^E + \Delta_z + 6 u_{33}^E - s_{33}}{2}$$
$$+ \sqrt{\frac{(\Delta_0 + 61_{00}^E + \Delta_z - 6 u_{33}^E + s_{33})^2}{4} + 2(t_{03}^E + 2 l_{03}^E)^2}$$

(C.14)

and

$$E_6(\Gamma) = \frac{\Delta_0 + 61_{00}^E + \Delta_z + 6 u_{33}^E - s_{33}}{2}$$
$$- \sqrt{\frac{(\Delta_0 + 61_{00}^E + \Delta_z - 6 u_{33}^E + s_{33})^2}{4} + 2(t_{03}^E + 2 l_{03}^E)^2}.$$  

(C.15)

Carrying out the same procedure for other blocks, we arrive at fully analytical expressions for all bands at the $\Gamma$ point. Thus each block correspond to a majority orbital composition and each eigenvalue (two for each block) is matched to a DFT value.

C.2. K point

At the $K$ point, $k_x = 2\pi/3a$ and $k_y = -2\pi/\sqrt{3}a$, resulting in $z_1 = e^{2\pi i/3}$ and $c_1 = e^{2\pi i/2}$. Then,

$$T_{K0}^{E,0} = \sqrt{2} \begin{pmatrix} i\sqrt{3} & t_{01}^t & t_{02}^t - t_{02}^l & 0 \\ i\sqrt{3} & t_{12}^t & t_{12}^l - t_{13}^t & 0 \\ t_{21}^l & t_{21}^t & i\sqrt{3} & t_{22}^t \\ t_{21}^l & t_{21}^t & i\sqrt{3} & t_{22}^t \end{pmatrix}.$$  

(C.16)

$$T_{K0}^{O,E} = \sqrt{2} \begin{pmatrix} t_{31}^t & t_{31}^t & i\sqrt{3} & t_{52}^t \\ i\sqrt{3} & t_{41}^t & t_{42}^l & t_{43}^l \\ t_{42}^l & t_{42}^t & i\sqrt{3} & t_{53}^t \\ t_{43}^l & t_{43}^t & i\sqrt{3} & t_{53}^t \end{pmatrix}.$$  

(C.17)

$$V_{K}^{E} = -\frac{3}{2} \begin{pmatrix} 21_{00}^E & 0 & 0 \\ 0 & v_{11}^E + v_{22}^E & 0 \\ 0 & 0 & v_{33}^E + v_{44}^E \end{pmatrix}.$$  

(C.18)

$$V_{K}^{O} = -\frac{3}{2} \begin{pmatrix} v_{33}^E + v_{44}^E & 0 \\ v_{44}^E + v_{33}^E & v_{44}^E + v_{33}^E \end{pmatrix}.$$  

(C.19)

where we have imposed $l_{03}^t = l_{03}^l$ and $s_{11} = s_{22}$.

The Hamiltonian matrix can be block diagonalized by a chiral transformation [27].

$$A_{R2, L2} = \frac{a_1 \pm ia_2}{\sqrt{2}}.$$  

(C.23)

$$A_{R1, L1} = \frac{a_1 \pm ia_4}{\sqrt{2}}.$$  

(C.24)

$$\theta_{R, L} = \frac{\theta_1 \pm i\theta_2}{\sqrt{2}}.$$  

(C.25)

$$\phi_{R, L} = \frac{\phi_1 \pm i\phi_3}{\sqrt{2}}.$$  

(C.26)

The other variables, $a_0$, $\phi_0$, and $\theta_0$, remain the same. Thus, we have the new state vector

$$\psi^T = (a_0, a_{L2}, a_{R2}, \theta_{L}, \theta_{R}, \phi_3, a_{L1}, a_{R1}, \phi_L, \phi_R, \theta_3).$$  

(C.27)

The result is

$$H = \begin{pmatrix} A & 0 \\ 0 & B \end{pmatrix}.$$  

(C.28)

where

$$A = \begin{pmatrix} \Delta_0 + V_{00}^E & 0 & 0 & 0 & 0 & \Delta_2 + V_{11}^E & 0 & \Delta_2 + V_{22}^E & \cdots \\ 0 & \Delta_2 + V_{11}^E & 0 & 0 & 0 & 0 & \Delta_2 + V_{22}^E & \cdots \\ 0 & 0 & \Delta_2 + V_{22}^E & \cdots & \cdots & \cdots & \cdots & \cdots \\ 0 & 0 & 0 & \Delta_2 + V_{11}^E & \cdots & \cdots & \cdots & \cdots \\ -i(K_{01} - K_{02}) & 0 & 0 & 0 & K_{31} - K_{32} & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & K_{32} - K_{33} & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & K_{31} - K_{32} & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & K_{31} - K_{32} & 0 & 0 \end{pmatrix}.$$  

(C.29)
and
\[
B = \begin{pmatrix}
\Delta_t + V_{00}^E & 0 & 0 & i(K_{01} - K_{02}) \\
0 & \Delta_t + V_{01}^E & 0 & 0 \\
0 & 0 & \frac{i}{2}(K_{01} - K_{04} - K_{02} - K_{12}) & 0 \\
0 & 0 & 0 & -i(K_{01} - K_{03})
\end{pmatrix}
\]
\[
\Delta_t + U_{11} - s_{11}
\]
\[
\Delta_t + U_{22} - s_{11}
\]
\[
\Delta_t + U_{33} + s_{11}
\]

The following elements have been introduced:
\[
K_{01} = \sqrt{3} \mathcal{f}_{11}^t, \quad K_{02} = t_{02}^t - t_{02}^l \\
K_{11} = \sqrt{3} \mathcal{f}_{12}^t, \quad K_{12} = t_{12}^t - t_{12}^l, \quad K_{13} = t_{13}^t - t_{13}^l, \quad K_{21} = t_{21}^t - t_{21}^l, \quad K_{22} = \sqrt{3} \mathcal{f}_{22}^t, \quad K_{23} = \sqrt{3} \mathcal{f}_{23}^t, \quad K_{31} = t_{31}^t - t_{31}^l, \quad K_{32} = \sqrt{3} \mathcal{f}_{32}^t, \quad K_{33} = \sqrt{3} \mathcal{f}_{33}^t, \quad K_{41} = \sqrt{3} \mathcal{f}_{41}^t, \quad K_{42} = t_{42}^t - t_{42}^l, \quad K_{43} = t_{43}^t - t_{43}^l
\]

Using the SK decomposition, one finds that several combinations of these coefficients yield zero. These simplifications have already been implemented in equations (C.29) and (C.30). The \( H \) matrix breaks up into five \( 2 \times 2 \) blocks and one \( 1 \times 1 \) block,

\[
E_{\text{conductance}}(K) = \frac{\Delta_0 + V_{00}^E + \Delta_p + U_{11}^E + s_{11}}{2} + \sqrt{\frac{(\Delta_0 + V_{00}^E - \Delta_p - U_{11}^E - s_{11})^2}{4} + (K_{01} - K_{02})^2}
\]

and

\[
E_{\text{valence}}(K) = \frac{\Delta_2 + V_{11}^E + \Delta_p + U_{22}^E + s_{11}}{2} + \sqrt{\frac{(\Delta_2 + V_{11}^E - \Delta_p - U_{22}^E - s_{11})^2}{4} + (K_{11} - K_{21} - K_{12} - K_{22})^2 \frac{2}{2}}
\]

- \( \alpha_{l2} - \theta_K \):
\[
\begin{pmatrix}
\Delta_2 + V_{11}^E & i(K_{11} - K_{21} + K_{12} + K_{22})/\sqrt{2} \\
-i(K_{11} - K_{31} + K_{12} + K_{22})/\sqrt{2} & \Delta_p + U_{22}^E + s_{11}
\end{pmatrix}
\]

- \( \alpha_{l1} - \theta_K \):
\[
\begin{pmatrix}
\Delta_1 + V_{22}^E & i(K_{13} - K_{23}) \\
-i(K_{13} - K_{43}) & \Delta_p + U_{22}^E + s_{11}
\end{pmatrix}
\]

According to the DFT-HSE06 calculations, at the \( K \) point, the conductance band is mainly composed by \( d_{x^2-y^2}, p_y \), and \( p_y \) orbitals, while the valence band is mainly formed by \( d_{xy}, d_{z^2}, p_x \), and \( p_y \) orbitals. Therefore, the conductance band can be obtained from \( \alpha_{l2} - \theta_K \) variables, while the valence band comes from the \( \alpha_{l2} - \theta_K \) combinations, resulting in the expressions

Following the same procedure for other blocks, we find analytical expressions for nearly all energies at the \( K \) point. Thus, each block corresponds to a majority orbital composition and each eigenvalue (two for each block \( 2 \times 2 \)) is matched to a DFT-HSE06 value.

**Appendix D. Alternative implementation of unsymmetrized band equations and comparison with the tight-binding model of Cappelluti et al**

The essential difference between our construction of the 11-orbital and that of Cappelluti et al \cite{27,28} comes from
their inclusion of two phase factors in the Bloch state equation, namely,

\[ |\mathbf{k}\rangle = \sum_{\mathbf{r}} e^{i\mathbf{k}\cdot\mathbf{r}} \left( \sum_{\mu=0}^{4} a_{\mathbf{k},\mu}|\mathbf{r}; d_{\mu}\rangle + \sum_{\mu=1}^{3} (\hat{h}_{\mathbf{k},\mu} e^{i\mathbf{k}\cdot\mathbf{r}_{\mu}}|\mathbf{r} + \delta_{1}\rangle|p_{\mu}\rangle) \right) \]

(D.1)

Comparing this equation with equation (B.2), we notice the extra phase factors in the amplitudes of the S atomic orbitals.

While the phase factors have no impact on the eigenvalue secular equation, they do change the matrices containing hopping amplitudes between Mo and S atoms. For instance, our \( T \) matrix of equation (B.12) would change to

\[ T' = [t' + z_{2} z_{1}(I' + z_{2} I')]e^{i\mathbf{k}\cdot\mathbf{r}_{s}}. \]

(D.2)

A second yet important difference between their work and ours is on the notation and organization of the hopping matrices.

To facilitate a direct comparison between our model and that of [27, 28], we begin by swapping the second and third rows and corresponding columns in equation (B.9).

\[
\begin{pmatrix}
 h^{2} + U & T^{y} \\
 T^{t} & h^{2} + U + V
\end{pmatrix}
\begin{pmatrix}
 \xi \\
 \beta
\end{pmatrix}
= E
\begin{pmatrix}
 \xi \\
 \beta
\end{pmatrix}
\]

(D.3)

Next we introduce our auxiliary quantities \( \xi = k_{y} a/2 \) and \( \eta = \sqrt{3} k_{x} a/2 \), which allows us to rewrite the coefficients in equations (B.6)–(B.8) as

\[ c_{1} = \cos(2\xi), \]

(D.4)

\[ c_{2} = \cos(\xi + \eta), \]

(D.5)

and

\[ c_{12} = \cos(\xi - \eta). \]

(D.6)

Also, \( z_{1} = e^{2i\xi}, z_{2} = e^{i\xi+\eta} \), and

\[ e^{i\mathbf{k}\cdot\mathbf{r}_{1}} = e^{2im/3} \]

(D.7)

\[ e^{i\mathbf{k}\cdot\mathbf{r}_{2}} = e^{-i(\xi+\eta)/3} \]

(D.8)

\[ e^{i\mathbf{k}\cdot\mathbf{r}_{3}} = e^{i(\xi-\eta)/3}. \]

(D.9)

The correspondence between our block matrices and theirs is the following (phase factors set to zero in the appropriate hopping amplitudes):

- \( S \leftrightarrow H_{pt, pb} \), with

\[ H_{pt, pb} = \begin{pmatrix}
 V_{pp} & 0 & 0 \\
 0 & V_{pp} & 0 \\
 0 & 0 & V_{pp}
\end{pmatrix} \]  

(D.11)

- \( h^{Mo} + V \leftrightarrow H_{d, dt} \), with

\[ H_{d, dt} = \begin{pmatrix}
 H_{\zeta_{x}, \zeta_{x}} & H_{\zeta_{x}, \zeta_{y}} & H_{\zeta_{x}, \zeta_{z}} \\
 H_{\zeta_{y}, \zeta_{x}} & H_{\zeta_{y}, \zeta_{y}} & H_{\zeta_{y}, \zeta_{z}} \\
 H_{\zeta_{z}, \zeta_{x}} & H_{\zeta_{z}, \zeta_{y}} & H_{\zeta_{z}, \zeta_{z}}
\end{pmatrix} \]  

(D.12)

- \( T^{\theta} \leftrightarrow H_{d, pt} \), with

\[ H_{d, pt} = \begin{pmatrix}
 H_{\zeta_{x}, \zeta_{x}} & H_{\zeta_{y}, \zeta_{y}} & H_{\zeta_{z}, \zeta_{z}} \\
 H_{\zeta_{y}, \zeta_{y}} & H_{\zeta_{z}, \zeta_{z}} & H_{\zeta_{z}, \zeta_{z}} \\
 H_{\zeta_{z}, \zeta_{z}} & H_{\zeta_{z}, \zeta_{z}} & H_{\zeta_{z}, \zeta_{z}}
\end{pmatrix} \]  

(D.13)

- \( T^{\theta} \leftrightarrow H_{d, pb} \), with

\[ H_{d, pb} = \begin{pmatrix}
 -H_{\zeta_{x}, \zeta_{x}} & H_{\zeta_{y}, \zeta_{y}} & H_{\zeta_{z}, \zeta_{z}} \\
 -H_{\zeta_{y}, \zeta_{y}} & H_{\zeta_{z}, \zeta_{z}} & H_{\zeta_{z}, \zeta_{z}} \\
 -H_{\zeta_{z}, \zeta_{z}} & H_{\zeta_{z}, \zeta_{z}} & H_{\zeta_{z}, \zeta_{z}}
\end{pmatrix} \]  

(D.14)

All matrix elements are identical to those of [27], except for the matrices \( H_{d, pt} \) and \( H_{d, pb} \), which are explicitly defined below:

\[ H_{\zeta_{x}, \zeta_{x}} = -2\sqrt{3} E_{1} \sin(\xi) d_{1} \]

(D.15)

\[ H_{\zeta_{y}, \zeta_{y}} = 2E_{1} C_{2} \]

(D.16)

\[ H_{\zeta_{z}, \zeta_{z}} = E_{2} C_{1} \]

(D.17)

\[ H_{\zeta_{x}, \zeta_{x}} = -2\sqrt{3} \left( \frac{1}{3} E_{5} - E_{3} \right) \sin(\xi) d_{1} \]

(D.18)

\[ H_{\zeta_{y}, \zeta_{y}} = H_{\zeta_{x}, \zeta_{x}} \]

(D.19)

\[ H_{\zeta_{z}, \zeta_{z}} = -2 \sqrt{3} E_{5} \sin(\xi) d_{1} \]

(D.20)

\[ H_{\zeta_{x}, \zeta_{x}} = H_{\zeta_{y}, \zeta_{y}} \]

(D.21)

\[ H_{\zeta_{z}, \zeta_{z}} = 2E_{6} C_{2} \]

(D.22)

\[ H_{\zeta_{y}, \zeta_{y}} = -2E_{3} C_{3} + 2iE_{5} \cos(\xi) d_{1} \]

(D.23)

\[ H_{\zeta_{z}, \zeta_{z}} = 2E_{2} C_{2} \]

(D.24)
\[ H_{y, z} = -\frac{2}{3} E_5 C_3 + 6i E_3 \cos(\xi) \, d_1 \]  
(D.25)
\[ H_{y, z} = -2\sqrt{3} E_4 \sin(\xi) d_1 \]  
(D.26)
\[ H_{z, y} = -2\sqrt{3} \left( \frac{1}{3} E_6 - E_7 \right) \sin(\xi) \, d_1 \]  
(D.27)
\[ H_{x, z} = -\frac{2}{3} E_6 C_3 + 6i E_3 \cos(\xi) \, d_1 \]  
(D.28)
\[ H_{x, z} = -2 E_7 C_3 + 2i E_6 \cos(\xi) \, d_1 \]  
(D.29)
In all these equations the quantities \( l_1, l_2 \) and \( l_3 \), as well \( E_i \), 
\( i = 1, \ldots, 8 \), follow the definitions of [27]; for instance,
\[ l_1 = \cos(2\xi) + 2 \cos(\xi) \cos(\eta) \]  
(D.30)
\[ l_2 = \cos(2\xi) - \cos(\xi) \cos(\eta) \]  
(D.31)
\[ l_3 = 2 \cos(2\xi) + \cos(\xi) \cos(\eta) \]  
(D.32)
The coefficients \( C_1, C_2, C_3, \) and \( d_1 \) become more compact 
without the inclusion of phases, namely,
\[ C_1 = -1 - 2 \cos(\xi) \cos(\eta) + 2i \cos(\xi) \sin(\eta) \]  
(D.33)
\[ C_2 = -1 + \cos(\xi) \cos(\eta) - i \cos(\xi) \sin(\eta) \]  
(D.34)
\[ C_3 = \cos(\xi) \cos(\eta) - i \cos(\xi) \sin(\eta) + 2 \]  
(D.35)
\[ d_1 = i \cos(\eta) + \sin(\eta). \]  
(D.36)
