(Dated: May 2, 2014)

Using density functional theory calculations including a Hubbard $U$ term we explore the effect of strain and confinement on the electronic ground state of superlattices containing the band insulator LaAlO$_3$ and the correlated metal LaNiO$_3$. Besides a suppression of holes at the apical oxygen, a central feature is the asymmetric response to strain in single unit cell superlattices: For tensile strain a band gap opens due to charge disproportionation at the Ni sites with two distinct magnetic moments of 1.45$\mu_B$ and 0.71$\mu_B$. Under compressive strain, charge disproportionation is nearly quenched and the band gap collapses due to overlap of $d_{3z^2-r^2}$ bands through a semimetallic state. This asymmetry in the electronic behavior is associated with the difference in octahedral distortions and rotations under tensile and compressive strain. The ligand hole density and the metallic state are quickly restored with increasing thickness of the (LaAlO$_3$)$_n$/LaNiO$_3$$_n$ superlattice from $n = 1$ to $n = 3$.

The ability to grow transition metal oxide heterostructures with atomic control of layer thickness opens an exciting realm to explore confinement effects and novel effectively two-dimensional electronic phases that are not accessible in the bulk compounds. To this end, Chaloupka and Khaliullin$^1$ recently proposed that a cuprate-like behavior may be stabilized in a La$_2$NiMO$_6$ superlattice (SL) where NiO$_2$ and MO$_2$ planes alternate along the $c$-axis of the ABO$_3$ perovskite lattice and M denotes a trivalent cation (M=Al, Ga, Ti). LaNiO$_3$ is a perovskite compound with rhombohedral symmetry ($R$$\bar{3}$c) that remains metallic at all temperatures due to degenerate $e_g$ orbitals at the Ni$^{3+}$-sites ($t_{2g}^{3/2}$, $g^{1/2}$, $S = 1/2$). In contrast to bulk LNO, all other representatives of the rare earth nickelates undergo a metal-to-insulator transition (MIT)$^2$ at low temperatures, driven by charge ordering (CO) rather than the Jahn-Teller effect.$^{56}$ Chaloupka and Khaliullin$^1$ proposed that the orbital degeneracy in LNO/LMO superlattices can be lifted and a selective $d_{3z^2-r^2}$ or $d_{2y^2-r^2}$ occupation at the Ni$^{3+}$ sites achieved by applying strain induced by the substrate. Subsequent density functional theory (DFT) calculations in the local density approximation (LDA) found a two sheet Fermi surface (FS) with strongly hybridized $d_{3z^2-r^2}$ and $d_{2y^2-r^2}$ orbitals.$^{56}$ A single-sheet FS could only be obtained by including correlation effects within the dynamical mean field approximation (DMFT) and/or by using Sc as counterion to Ni instead of Al.$^7$ Han et al.$^8$ showed that the choice of the counterion (Al, Ga, B, In) rather than strain can be used to control chemically the orbital polarization.

The DFT studies mentioned above have considered exclusively superlattices in a tetragonal setup. However, both LaNiO$_3$ (LNO) and LaAlO$_3$ (LAO) are rhombohedral in the bulk (space group $R$$\bar{3}$c). Here we explore the effect of confinement and strain on the octahedral distortions. DFT calculations with an on-site Coulomb repulsion term show that the lattice distortions have a significant influence on the bandwidth and thereby on the electronic ground state of the system. In particular, a charge disproportionated (CD) insulating state is obtained in LAO/LNO SLs under tensile strain. In a tetragonal cell such a state is reported only at higher $U$ values.$^7$ The tendency toward CD is vastly suppressed under compressive strain.

A metal-to-insulator transition as a function of LNO thickness has been observed experimentally for LaNiO$_3$/LaAlO$_3$$^9$ and LaNiO$_3$/SmMnO$_3$$^{11}$ superlattices as well as in thin LNO films grown on an STO(001) substrate.$^{12,13}$ The Ruddlesden-Popper compound La$_3$Ni$_2$O$_8$$^{14,15}$ is another example for an insulating state due to confinement. Here, we explore the effect of quantum confinement by varying the period of the (LAO)$_n$/LNO$_n$ superlattice from $n = 1$ to $n = 3$. The results show a quick convergence toward bulk metallic behavior within the LNO part of the superlattice with increasing thickness.

I. CALCULATIONAL DETAILS

To gain insight into the electronic behavior of (LAO)$_n$/LNO$_n$ ($n = 1, 3$) superlattices, we performed density functional theory calculations with the full potential linearized augmented plane wave method as implemented in the WIEN2k code.$^{16}$ An on-site Coulomb repulsion term is considered beyond the generalized gradient approximation$^7$ of the exchange correlation potential within the LDA/GGA$+U$ approach$^{15}$ using $U = 4$ eV and $J = 0.7$ eV for Ni and $U = 7$ and $J = 0$ eV for La. The muffin tin (MT) radii are 1.80 bohrs (Ni and Al), 2.30 bohrs (La) and 1.60 bohrs (oxygen). Inside the muffin tins, wave functions are expanded in spherical harmonics up to $l_{\text{max}}^{\text{ref}} = 10$ and nonspherical contributions to the electron density and potential are considered up to $l_{\text{max}}^{\text{pot}} = 6$. The energy cutoff for the plane wave representation in the interstitial is $E_{\text{max}}^{\text{ref}} = 25$ Ry for the wave functions and $E_{\text{max}}^{\text{pot}} = 144$ Ry for the potential. 76 $k$-points were used for the integration in the irreducible part of the Brillouin zone (BZ). To model the effect of substrate- induced strain, the in-plane lattice parameter of the superlattice was set to that of LAO ($a = 3.78\text{Å}$), STO ($a = 3.905\text{Å}$) or DyScO$_3$ (DSO) ($a = 3.94\text{Å}$), respectively. For the out-of-plane parameter we have used values obtained
from XRD measurements: 3.83 (STO) and 3.93 Å (LAO). Relaxations of the $c$ parameter for superlattices strained at $a_{DSO}$ rendered a $c$ value very similar to the one for the STO case. This implies a deviation from the volume conserving scenario for tensile strain, as also suggested from XRD measurements. While previous DFT studies have used a tetragonal setup, we explored the influence of strain on the octahedral rotations by optimizing the internal parameters in a monoclinic unit cell containing 20 atoms for LNO bulk and the 1/1 superlattice. In the present study parallel alignment of the Ni spins is considered. Calculations for antiferromagnetic configurations were unstable and higher in energy.

II. BULK LNO

Prior to studying the LAO/LNO superlattices we investigate here the electronic properties of LNO bulk. In order to facilitate comparison to the LNO/LAO superlattices the calculations are performed in a monoclinic unit cell containing 20 atoms. Figure 1(a) shows the projected density of states of the Ni 3$d$ character (black dotted line) obtained within GGA+$U$ ($U = 4$ eV and $J = 0.7$ eV). Positive (negative) values correspond to majority (minority) spin. Note that $d_{3z^2−r^2}$ (green line) and $d_{x^2−y^2}$ (orange dashed line) are degenerate in bulk LNO. (b) Electron density distribution of the unoccupied states integrated between $E_F$ and $E_F+2.5$ eV. La and O ions are denoted by purple and red spheres, respectively.

![Bulk LaNiO$_3$ projected density of states and electron density distribution](image)

FIG. 1: (Color online) Bulk LaNiO$_3$. (a) Projected density of states of Ni 3$d$ character (black dotted line) obtained within GGA+$U$ ($U = 4$ eV and $J = 0.7$ eV). Positive (negative) values correspond to majority (minority) spin. Note that $d_{3z^2−r^2}$ (green line) and $d_{x^2−y^2}$ (orange dashed line) are degenerate in bulk LNO. (b) Electron density distribution of the unoccupied states integrated between $E_F$ and $E_F+2.5$ eV. La and O ions are denoted by purple and red spheres, respectively.

The band structure of bulk LNO in Fig. 2 is plotted along the high-symmetry lines in the BZ of the 20-atom cell. We concentrate on the antibonding $e_g$ bands in the majority spin channel extending from -1 eV to 2 eV (in the minority spin channel these states are empty). At $\Gamma$ both $e_g$ bands are degenerate, $d_{3z^2−r^2}$ bands show a strong dispersion along $\Gamma−Z$, while $d_{x^2−y^2}$ bands are dispersive mainly along $Z−A−R−Z$. Both bands cross $E_F$ at $A$ and $d_{3z^2−r^2}$ also half-way along $R−Z$.

III. LAO/LNO SUPERLATTICES: ELECTRONIC PROPERTIES

A. (LaAlO$_3$)$_1$/ (LaNiO$_3$)$_1$ superlattices

We now turn to the (LaAlO$_3$)$_1$/ (LaNiO$_3$)$_1$ superlattices strained at the lateral lattice parameters of LAO, STO, and DSO. Their total density of states (DOS) are plotted in Fig. 3 together with the one for bulk LNO. For compressive strain (short-dashed cyan line) the system is (semi-)metallic with a dip of DOS at the Fermi level. Moreover, due to the stacking of insulating LAO and conducting LNO layers an enhanced resistivity is expected for (LaAlO$_3$)$_1$/ (LaNiO$_3$)$_1$ at $a_{STO}$. In contrast, for tensile strain a gap in the total density of states (Fig. 3) of 0.3 eV occurs above the Fermi level (solid line, gray area). Interestingly, the total DOS of (LaAlO$_3$)$_1$/ (LaNiO$_3$)$_1$ at $a_{DSO}$ almost coincides with the one for $a_{STO}$ around the Fermi level, implying a nonlinear dependence of the electronic properties on strain. Therefore, we concentrate in the following on the electronic properties of (LaAlO$_3$)$_1$/ (LaNiO$_3$)$_1$ strained at $a_{LAO}$ and $a_{STO}$.
Additionally, the orbital polarization of the occupied \( e_g \) states \( P = (n_{\sigma_{\gamma,\pi}} - n_{\sigma_{\gamma,\pi}}) / (n_{\sigma_{\gamma,\pi}} + n_{\sigma_{\gamma,\pi}}) \) and the magnetic moments are displayed. The last two columns give the number of holes \( \Delta p_{\sigma} \) (difference in occupation with respect to the fully occupied \( p_{\sigma} \) orbitals) of the apical (a) and basal (b) oxygen within the MT sphere.

In order to understand the origin of the distinct electronic behavior for tensile and compressive strain we analyze here the PDOS of the Ni 3d orbitals. Besides the filled \( t_{2g} \) orbitals there is a significant occupation of both \( e_g \) orbitals at the Ni sites (see Fig. 4) split into bonding (between -7 and -5 eV) and antibonding contributions (from -1 to 2 eV). The most striking effect for tensile strain is a charge disproportionation on the Ni sublattice, \( \text{Ni}^{3+} \rightarrow \text{Ni}^{3+} + \text{Ni}^{3-} \) where Ni1 has a stronger occupation of the \( e_g \) orbitals. The effect is most pronounced for the majority spin states with 0.87\( \epsilon \)/0.86\( \epsilon \) (Ni1) and 0.63\( \epsilon \)/0.71\( \epsilon \) (Ni2) in the \( d_{3z^2-r^2} \) orbitals, respectively. The reduced occupation in the majority spin channel at Ni2 is partially compensated by a stronger filling of minority states at -4.3 eV. Altogether, the total difference in \( e_g \) occupation at the Ni1 (\( \text{Ni}^{3-} \)) and Ni2 (\( \text{Ni}^{3+} \)) sites is \(-0.2\epsilon \), but there is a significant difference in the magnetic moments \( 1.45\mu_B \) (Ni1) and \( 0.71\mu_B \) (Ni2) (for comparison, the magnetic moment in LNO bulk is \( 1.12\mu_B \)). Without the octahedral tilts and rotations such a state is reported at \( U \approx 5 \) eV. A similar tendency for disproportionation was recently found in LNO films under tensile biaxial strain, but here as a result of confinement in the LAO/LNO superlattice the effect is strongly enhanced leading to the opening of a gap of \(-0.5 \) eV at the Fermi level. Concerning the orbital polarization, the two sites show opposite, largely compensating tendencies: a slightly higher occupation of \( d_{x^2-y^2} \) at Ni2 (+2.2\%)) and the reverse effect at Ni1 (-1.7\%).

For compressive strain the charge disproportionation is noticeably reduced, reflected in a much smaller difference in the
magnetic moments ($1.22 \mu_B$ at Ni1 and $0.98 \mu_B$ at Ni2). We note that a non-disproportionated configuration lies only 12 meV/20-atom unit cell higher in energy. The broadening of the conduction band leads to an overlap with the valence band which closes the band gap with a dip in the PDOS at $E_F$. As a consequence of the distortion (elongation) of the NiO6 octahedra discussed below, there is a stronger splitting between the $d_{3z^2-r^2}$ and $d_{x^2-y^2}$ states around $E_F$ and an enhanced occupation of the $d_{3z^2-r^2}$ orbital in the majority spin channel [0.86e ($d_{3z^2-r^2}$) vs 0.76e ($d_{x^2-y^2}$) at Ni1 and 0.77e ($d_{3z^2-r^2}$) vs 0.72e ($d_{x^2-y^2}$) at Ni2]. Taking into account the occupation of the minority spin channel the total number of electrons within the MT sphere is 1.06 ($d_{3z^2-r^2}$) vs 0.98 ($d_{x^2-y^2}$) at Ni1 and 1.02 ($d_{3z^2-r^2}$ vs 0.98 ($d_{x^2-y^2}$) at Ni2, respectively. This results in an orbital polarization of $-3.8\%$ and $-1.6\%$. We note that much higher values were obtained by Han et al.\textsuperscript{3} by integrating only over the antibonding states from $\sim -1.5$ eV to $E_F$.

To gain more insight in the electronic structure of the (LaAlO$_3$)$_3$/(LaNiO$_3$)$_1$ superlattice, we have plotted in Fig. 5 the band structure in the majority spin channel for compressive ($a_{\text{LaO}}$) and tensile ($a_{\text{STO}}$) strain. As a consequence of confinement in the superlattice the $d_{3z^2-r^2}$-band has a reduced dispersion compared to bulk LaNiO3 (Fig. 2) and the degeneracy of the two $e_g$ states at $\Gamma$ is lifted with the $d_{3z^2-r^2}$ state being 0.3 ($a_{\text{LaO}}$)/0.7 ($a_{\text{STO}}$) above $E_F$. The band structure around $E_F$ is dominated by more localized $d_{3z^2-r^2}$ bands and strongly dispersive $d_{x^2-y^2}$ bands (especially for compressive strain) with dispersion of the latter mainly along $Z - A - R - Z$. As already mentioned in the discussion of the PDOS, there is a stronger splitting between $d_{3z^2-r^2}$ and $d_{x^2-y^2}$ states for $a_{\text{LaO}}$ compared to $a_{\text{STO}}$. In contrast to bulk LNO (Fig. 2) a gap opens at A both for tensile and compressive strain. However, for compressive strain ($a_{\text{LaO}}$) the $d_{3z^2-r^2}$ band lies at the Fermi level along $Z - A$ and halfway along $R - Z$ causing a finite DOS at $E_F$. The upward shift of this band by $\sim 0.5$ eV opens a band gap for $a_{\text{STO}}$. While the valence band maximum is mainly determined by $d_{3z^2-r^2}$ (and to a lesser extent $d_{x^2-y^2}$) states of Ni1 at A hybridized with $p_z$ orbitals of the apical oxygen, the conduction band minimum is dominated by $d_{3z^2-r^2}$ states of Ni2, admixed with $d_{x^2-y^2}$ and $p_z$ bands of the respective apical oxygen. This results in a stronger suppression of ligand holes of the apical oxygen of Ni1.

The charge disproportionation at the Ni sites for $a_{\text{STO}}$ is visible in the spatial distribution of holes shown in Fig. 7. In contrast to the three-dimensional network of holes on the basal and apical oxygens in bulk LNO (Fig. 1(b), a striking feature in (LaAlO$_3$)$_3$/(LaNiO$_3$)$_1$ is the two-dimensional character of hole distribution within the LNO part of the superlattice due to a reduced number of holes in the $p_z$ orbital of the apical oxygen for both tensile and compressive strain (see also PDOS of oxygen in Fig. 4). At the same time, the in-plane oxygen orbital occupancies are very similar to those in bulk LNO. As a measure of the number of holes in Table I we have determined the difference in filling between $p_r$ and the fully occupied $p_n$ orbitals. We note that we consider here only the occupation within the MT sphere, which contains 60-70% of the total charge of oxygen. In bulk LNO there are 0.19 less electrons in the $p_r$ than in the $p_n$ orbital within the MT. This number is reduced to 0.09 – 0.15$e$ for the apical oxygens in the superlattice. The suppression is strongest for the apical oxygen of Ni1 (Ni$^{3+}$) which simultaneously has a higher $d_{3z^2-r^2}$ occupation. Thus the suppression of holes due to the stronger ionicity of the Al$^{3+}$-O-bond across the interface and the charge disproportionation at the Ni sites with more ionic and more covalent contributions at the two distinct Ni-sites are the crucial mechanisms in achieving an insulating state in
FIG. 7: (Color online) Electron density distribution of the unoccupied states integrated between $E_F$ and $E_F + 2.5$ eV in (LAO)$_n$/LNO)$_1$ for (a) compressive (LAO) and (b) tensile (STO) strain. Note the reduction in hole density on the apical oxygen between Ni and Al, as well as the change in disproportionation at the Ni sites for tensile strain. La, O, and Al ions are shown in purple, red, and light gray, respectively.

$\text{(LaAlO}_3)_1/\text{(LaNiO}_3)_1$

B. $\text{(LaAlO}_3)_3/\text{(LaNiO}_3)_3$ superlattices

We turn now to the effect of LNO thickness on the electronic properties of the superlattice. The projected density of states (PDOS) at the Ni sites in (LAO)$_3$/LNO$_3$ at $\alpha_{STO}$ is displayed in Fig. 8. Unlike the (LaAlO)$_3$/LNO$_3$ system, there is a finite DOS at $E_F$ at the Ni sites both in the IF and IF-1 layer and no evidence for charge disproportionation. The $\epsilon_g$ states are nearly degenerate with a similar width as in the bulk and a small peak at $E_F$. Its character is predominantly $d_{3z^2-r^2}$ in the interface layer (IF) and Ni $d_{x^2-y^2}$ in IF-1 layer. As shown in the majority spin band structure in Fig. 9, these bands cross $E_F$ at $A$ [note that in (LaAlO)$_3$/LNO$_3$ a band gap opens at $A$]. The $d_{3z^2-r^2}$ bands of the two distinct layers (IF and IF-1) are split, with the IF band being narrower and lying lower in energy. In contrast to recent soft x-ray reflectivity measurements on (LaAlO)$_3$/LNO$_3$, we find only a small orbital polarization both in the interface (0.8%) and IF-1 (-0.3%) layers.

Figure 8(b) shows the hole density distribution integrated between $E_F$ and $E_F + 2.5$ eV. Besides the similar hole density at the Ni sites independent of their position with respect to the interface, we observe again a reduced hole density at the apical oxygen at the interface. However, the O$_{2p_z}$ hole density is quickly restored to nearly bulk LNO behavior already in the next layer. This quick recovery of bulk LNO behavior at the apical oxygen away from the interface and the metallic state at the Ni sites with no evidence for charge disproportionation are instrumental for the insulator-to-metal transition in the (LNO)$_n$/LAO)$_n$ SLs with increasing $n$, consistent with recent experiments.$^{9,10}$

FIG. 8: (Color online) (a) Projected density of states (PDOS) of 3$d$ states for Ni at interface (IF) and in the central layer (IF-1) in (LaAlO)$_3$/LNO$_3$ for tensile (STO) strain. Total 3$d$, $d_{3z^2-r^2}$ and $d_{x^2-y^2}$ character are denoted by black dotted, green, and orange dashed line, respectively. (b) Electron density distribution of unoccupied states (yellow) integrated between $E_F$ and $E_F + 2.5$ eV. Note that only half of the simulation cell is shown. For color coding see Fig. 7.

FIG. 9: (Color online) Majority spin band structure of (LaAlO)$_3$/LNO$_3$ for tensile (STO) strain. Note the splitting of $d_{3z^2-r^2}$ bands (green triangles) of Ni in the interface (IF) and (IF-1) layer, respectively. $d_{x^2-y^2}$ bands are emphasized by orange circles.
IV. STRAIN AND CONFINEMENT INDUCED LATTICE DEFORMATIONS

Not only the electronic but also the structural properties of the superlattice show a strongly asymmetric response to strain. The bond lengths and angles of the superlattices in comparison to bulk LNO and LAO are displayed in Table II and Fig. 10. For compressive strain the in-plane Ni-O bond length (1.92 Å) in (LaAlO$_3$)$_3$/(LaNiO$_3$)$_1$ is significantly shorter than the out-of-plane distance (2.01 Å), which is consistent with a volume-conserving tetragonal distortion and a crystal-field splitting between the $d_{3z^2-r^2}$ and $d_{2x^2-y^2}$ orbitals observed in Fig. 4(a). In contrast, the charge disproportionation for tensile strain goes hand in hand with bond disproportionation driven by a breathing mode with two nearly regular octahedra with in-/out-of-plane cation-anion distances of 2.02/1.99 Å and 1.93/1.93 Å at the Ni1 and Ni2 sites at $a_{\text{STO}}$, respectively.

As mentioned previously, in the bulk both LAO and LNO attain a rhombohedral structure with rotations of the octahedra around all three pseudocubic axes by $\alpha = \beta = \gamma = 3.04^\circ$ (LAO) and 5.4$^\circ$ (LNO). This corresponds to Glazer’s notation $^{26}$ ($a^+,-, a^-,-$). Recent DFT calculations$^{27}$ have found that under compressive strain the in-plane rotations of LAO are suppressed and the rotation pattern changes to ($a^0,+ , a^-,$). Vice versa for tensile strain the rotations are around the [101] direction ($a^-,-, a^-,-, e^0$). In contrast, an ($a^+,-, a^-,-, e^-$) pattern was reported in a combined XRD and DFT study$^{27}$ on strained LNO films with a strong reduction of $\gamma = 0.3 \pm 0.7^\circ$ and enhanced $\alpha = 7.1 \pm 0.2^\circ$ for tensile ($a_{\text{STO}}$) and an opposite trend for compressive ($a_{\text{STO}}$) strain ($\alpha = 1.7 \pm 0.2^\circ$ and $\gamma = 7.9 \pm 0.9^\circ$). While the general pattern of octahedral rotations is preserved in the (LaAlO$_3$)$_3$/(LaNiO$_3$)$_1$ superlattice, the presence of the interface and the different strain state in the LAO and LNO part imposed by the substrate lead to significant changes of the absolute values of rotation angles compared to the individual phases described above. The rotational angle of the NiO$_6$ octahedra around [100] increases with strain from $\alpha \sim 4.7^\circ$ ($a_{\text{STO}}$) to $\sim 6.1^\circ$ ($a_{\text{STO}}$) and $\sim 7.2^\circ$ ($a_{\text{DSO}}$), whereas $\gamma$ remains constant $\sim 6.2^\circ$. On the other hand, for the AlO$_6$ octahedra the rotational angle around [001] changes from $\gamma = 4.4^\circ$ (compressive) to $\sim 2.5^\circ$ (tensile strain).

The cation-oxygen-cation bond angles have a direct influence on the band width. In bulk LNO the Ni-O-Ni angle is $164.8^\circ$. In LAO, the deviation of the Al-O-Al angle from $180^\circ$ is smaller ($171.4^\circ$). For compressive strain: the out-of-plane Ni-O-Al angle in (LaAlO$_3$)$_3$/(LaNiO$_3$)$_1$ is increased to $\sim 166 - 167^\circ$, while the in-plane Ni-O-Ni angle decreases to $163^\circ$ (the in-plane Al-O-Al angle, $165.6^\circ$, is also reduced w.r.t. the bulk value). In contrast, for tensile strain both the in- (Ni-O-Ni) and out-of-plane (Ni-O-Al) bond angles are significantly reduced to $\sim 162^\circ$ for $a_{\text{STO}}$ and $\sim 161 - 162^\circ$ for $a_{\text{DSO}}$. The Al-O-Al is $167.3^\circ$, again smaller than the corresponding angle in bulk LAO ($171.4^\circ$). The decrease of bond angles reduces the bandwidth of $d_{3z^2-r^2}$ and $d_{2x^2-y^2}$ bands between $E_F$ and $E_F+4$ eV, as can be seen in the PDOS in Fig. 4b). The Ni-O-Ni angle has been previously identified as the control parameter of the MIT in rare earth nickelates, where a smaller deviation from $180^\circ$ favors Ni 3d-$O_2p$ hybridization and a metallic state, while a strong deviation leads to a MIT$^3$. Indeed, the values we obtain for tensile strain ($160 - 162^\circ$) are close to the Ni-O-Ni angles in PrNiO$_3$ ($158.7^\circ$) and NdNiO$_3$ ($157.1^\circ$) that undergo a MIT.

In the (LaAlO$_3$)$_3$/(LaNiO$_3$)$_1$ superlattice under tensile strain ($a_{\text{STO}}$) the octahedra are nearly regular with an in-/out-of-plane Ni-O bond length of 1.97/1.95 Å (IF) and 1.97/1.97 Å (IF-1), respectively. The pattern of octahedral rotations is preserved with almost identical absolute values of rotation angles compared to the (LaAlO$_3$)$_3$/(LaNiO$_3$)$_1$ at $a_{\text{STO}}$. The out-of-plane Ni-O-Al (164$^\circ$) and Ni-O-Ni (162$^\circ$) and in-plane Ni-O-Ni ~ 162$^\circ$ (IF)/163$^\circ$ (IF-1) are slightly higher than the ones for the (LaAlO$_3$)$_3$/(LaNiO$_3$)$_1$ superlattice in line with the metallicity of the system.

V. SUMMARY

While in the bulk LNO is metallic at all temperatures with degenerate $e_g$ orbitals, we find that quantum confinement together with tensile strain allows to stabilize an insulating state in a (LaAlO$_3$)$_3$/(LaNiO$_3$)$_1$ superlattice. The charge disproportionation at the Ni sublattice with one strongly and one weakly magnetic Ni ion is fostered by the lattice response to strain, expressed in decreasing bond angles and enhanced tilt and rotation angles that reduce the band width. The charge...
ordered state in the (LaAlO$_3$)$_3$/[LaNiO$_3$]$_1$ SL under tensile strain is characterized by two nearly regular octahedra with distinct bond lengths and hence a reduced crystal field splitting at the Ni-sites. On the other hand, under compressive strain bands broaden and close the band gap and CD is strongly inhibited. Expansion of the out-of-plane Ni-O bond length results in a crystal-field splitting between the $d_{x^2-y^2}$ and $d_{z^2}$ orbitals and an energy lowering of the latter [see Fig. 4(b)]. This is similar to previous results for LNO films under compressive strain.

LAO/LNO superlattices and strained LNO films show similar tilt patterns but different magnitude of octahedral rotations. This gives further evidence that the lattice response to strain in superlattices is very different from the one in thin films and thus provides a further possibility to tune the band width and electronic behavior in transition metal oxides, as recently reported for LNO/SMO SLs.\(^\text{28}\)

The large band width of the $e_g$ states precludes significant changes in the orbital occupation via strain. The lack of lifting of orbital degeneracy is similar to other nickelates, e.g., NdNiO$_3$ where the MIT is not associated with orbital ordering.\(^\text{29,30}\) Recently, Mazin empl et al.\(^\text{4}\) proposed that the CO state in rare-earth nickelates gets gradually suppressed under pressure due to overlap of bands. In the confined (LaAlO$_3$)$_3$/[LaNiO$_3$]$_1$ we observe an analogous “melting” of the CD state as a function of strain: The significant difference in magnetic moments at the two distinct sites Ni1 and Ni2 sites at $\theta_{\text{STO}}$ is gradually reduced for compressive strain.

The insulating state in the (LaAlO$_3$)$_3$/[LaNiO$_3$]$_1$ superlattice is achieved through a combination of charge disproportionation and a reduction of the hole density on the apical oxygens at the interface due to the ionic bonding to Al. The metallic behavior at the Ni sites and the hole density of the apical oxygen in inner layers is quickly restored in (LaAlO$_3$)$_3$/[LaNiO$_3$]$_3$ superlattices, in line with recent observations of a MIT with increasing LNO thickness.\(^\text{3,10}\) We note that due to the presence of a surface, the mechanism of MIT in single layer films\(^\text{12,13}\) may be different and requires further investigation.

---

**Table II**: Ni-oxygen out-of-plane ($d_{Ni-O}$) and in-plane ($d_{Ni-O^b}$) distances, out-of-plane bond angle $\theta_c$ (Al-O-Ni), and in-plane angle $\theta_{ab}$ (Ni-O-Ni). Additionally, the rotation $\theta$ and tilt $\phi$ angles, as well as Glazer’s rotation angles $\alpha$ and $\gamma$, are displayed.

|        | $d_{Ni-O^b}$ | $d_{Ni-O^b}$ | $\theta_c$ | $\theta_{ab}$ | $\theta$ | $\phi$ | $\alpha$ | $\gamma$ |
|--------|--------------|--------------|------------|---------------|----------|--------|----------|---------|

31 Although due to covalency the Ni 3d band occupation is a mixture of 3d<sup>7</sup> and 3d<sup>8</sup>L ground state, we use here for clarity the formal oxidation state of Ni.
