$k$-colouring $(m, n)$-mixed graphs with switching

Richard C. Brewster, Arnott Kidner, Gary MacGillivray

March 16, 2022

Abstract

A mixed graph is a set of vertices together with an edge set and an arc set. An $(m, n)$-mixed graph $G$ is a mixed graph whose edges are each assigned one of $m$ colours, and whose arcs are each assigned one of $n$ colours. A switch at a vertex $v$ of $G$ permutes the edge colours, the arc colours, and the arc directions of edges and arcs incident with $v$. The group of all allowed switches is $\Gamma$.

Let $k \geq 1$ be a fixed integer and $\Gamma$ a fixed permutation group. We consider the problem that takes as input an $(m, n)$-mixed graph $G$ and asks if there a sequence of switches at vertices of $G$ with respect to $\Gamma$ so that the resulting $(m, n)$-mixed graph admits a homomorphism to an $(m, n)$-mixed graph on $k$ vertices. Our main result establishes this problem can be solved in polynomial time for $k \leq 2$, and is NP-hard for $k \geq 3$. This provides a step towards a general dichotomy theorem for the $\Gamma$-switchable homomorphism decision problem.

1 Introduction

Homomorphisms of graphs (and in general relational systems) are well studied generalizations of vertex colourings \cite{10}. Given a graph (or some generalization) $G$, the question of whether $G$ admits a $k$-colouring, can be equivalently rephrased as “does $G$ admit a homomorphism to a target on $k$ vertices?”. In this paper we study homomorphisms of $(m, n)$-mixed graphs endowed with a switching operation under some fixed permutation group. (Formal definitions and precise statements of our results are given below.) Our main result is that the 2-colouring problem under these homomorphisms can be solved in polynomial time. As $k$-colouring for classical graphs can be encoded within our framework, $k$-colouring in our setting is NP-hard for fixed $k \geq 3$. That is, $k$-colouring for $(m, n)$-mixed graphs with a switching operation exhibits a dichotomy analogous to $k$-colouring of classical graphs \cite{7}. Thus, our work maybe viewed as

a first step towards a dichotomy theorem for homomorphisms of \((m,n)\)-mixed graphs with a switching operation. We remark that the \(k\)-colouring problem in our setting is not obviously a Constraint Satisfaction Problem [4,6,19] nor is membership in NP clear. These ideas are explored further in a companion paper [3].

We begin with the key definitions to state our main result. In this paper, all graphs and all groups are finite.

A **mixed graph** is a triple \(G = (V(G), E(G), A(G))\) consisting of a set of vertices \(V(G)\), a set of edges \(E(G)\) of unordered pairs of vertices, and a set of arcs \(A(G)\) of ordered pairs of vertices. Given pair of vertices \(u \text{ and } v\), there is at most one edge, or one arc, but not both, joining them. Further we assume \(G\) is loop-free. We will use \(uv\) to denote an edge or an arc with end points \(u\) and \(v\) where in the latter case the arc is oriented from \(u\) to \(v\).

Mixed graphs were introduced by Nešetřil and Raspaud [15] as an attempt to unify the theories of homomorphisms of 2-edge coloured graphs and of oriented graphs. Numerous similarities between the two settings have been observed (see for example, [1,12,16]), whereas, Sen [17] provides examples highlighting key differences.

In this work we study edge and arc coloured generalizations of mixed graphs. Thus, our work may be viewed as a unification of homomorphisms of edge-coloured graphs and of arc-coloured graphs. Let \(m\) and \(n\) be non-negative integers. Denote by \([m]\) the set \(\{1,2,\ldots,m\}\). An \((m,n)\)-mixed graph is a mixed graph \(G = (V(G), E(G), A(G))\) together with functions \(c : E(G) \rightarrow [m]\) and \(d : A(G) \rightarrow [n]\) that assign to each edge one of \(m\) colours, and to each arc one of \(n\) colours respectively. (The colour sets for edges and arcs are disjoint.) The **underlying mixed graph** of \(G\) is \((V(G), E(G), A(G))\), i.e., the mixed graph obtained by ignoring edge and arc colours. The **underlying graph** of \(G\) is the graph obtained by ignoring edge and arc colours and arc directions. An \((m,n)\)-mixed graph is a cycle if its underlying graph is a cycle and similarly for other standard graph theoretic terms such as path, tree, bipartite, etc.

Fundamental to our work is the following definition. An \((m,n)\)-mixed graph is **monochromatic of colour** \(i\) if either every edge is colour \(i\) and there are no arcs, or every arc is colour \(i\) and there are no edges. While a monochromatic mixed graph with only edges is naturally isomorphic to its underlying graph, we note that we still view the edges as having colour \(i\).

Let \(G\) and \(H\) be \((m,n)\)-mixed graphs. A **homomorphism** of \(G\) to \(H\) is a function \(h : V(G) \rightarrow V(H)\) such that if \(uv\) is an edge of colour \(i\) in \(G\), then \(h(u)h(v)\) is an edge of colour \(i\) of \(H\), and if \(uv\) is an arc of colour \(j\) in \(G\), then \(h(u)h(v)\) is an arc of colour \(j\) in \(H\). We denote the existence of a homomorphism of \(G\) to \(H\) by \(G \rightarrow H\) or \(h : G \rightarrow H\) when the name of the function is required.

We now turn our attention to the concept of switching an \((m,n)\)-mixed graph at a vertex \(v\). This generalizes the concept of switching edge colours or signs [2,18] (permuting the colour of edges incident at \(v\)) and pushing digraphs [11] (reversing the direction of arcs incident at \(v\)). Let \(\Gamma \leq S_m \times S_n \times S_n^2\) be a permutation group. An element of \(\Gamma\) will act on edge colours, arc colours, and arc directions. Specifically, the element is an ordered \((n+2)\)-tuple \(\pi =\)
Let $G$ be a $(m,n)$-mixed graph, and $\pi = (\alpha, \beta, \gamma_1, \gamma_2, \ldots, \gamma_n) \in \Gamma$. Define $G^{(v,\pi)}$ as the $(m,n)$-mixed graph arising from $G$ by switching at vertex $v$ with respect to $\pi$ as follows. Replace each edge $uv$ of colour $i$ by an edge $vw$ of colour $\alpha(i)$. Replace each arc $a$ of colour $i$ incident at $v$ (i.e., $a = vx$ or $a = xv$) with an arc of colour $\beta(i)$ and orientation $\gamma_i(a)$. Note, $\gamma_i(a) \in \{vx, xv\}$.

Given a sequence of ordered pairs from $V(G) \times \Gamma$, say $\Sigma = (v_1, \pi_1)(v_2, \pi_2)\ldots(v_k, \pi_k)$, we define switching $G$ with respect to the sequence $\Sigma$ as follows:

$$G^{\Sigma} = (G^{(v_1,\pi_1)}(v_2,\pi_2)\ldots(v_k,\pi_k)) = (G^{(v_1,\pi_1)}(v_2,\pi_2)(v_3,\pi_3)\ldots(v_k,\pi_k)).$$

Note if we let $\Sigma^{-1} = (v_k, \pi_k^{-1})\ldots(v_1, \pi_1^{-1})$, then $G^{\Sigma\Sigma^{-1}} = G^{\Sigma^{-1}\Sigma} = G$.

Given a subset of vertices, $X \subseteq V(G)$, we can switch at each vertex of $X$ with respect to a permutation $\pi \in \Gamma$, the result of which we denote by $G^{(X,\pi)}$. This operation is well defined independently of the order in which we switch. If $uv$ is an edge or arc with one end in $X$, say $u$, then we simply switch at $u$ with respect to $\pi$. Suppose both ends of $uw$ are in $X$. If $uv$ is an edge of colour $i$, then after switching at each vertex of $X$, the edge will have colour $\alpha^2(i)$. If $uv$ is an arc, then after switching the colour will be $\beta^2(i)$ and the direction will be $\gamma_{\beta(i)}^2 \gamma_i(uv)$.

Two $(m,n)$-mixed graphs $G$ and $G'$ with the same underlying graph are $\Gamma$-switch equivalent if there exists a sequence of switches $\Sigma$ such that $G^{\Sigma} = G'$. We may simply say switch equivalent when $\Gamma$ is clear from context. Note since $V(G) = V(G')$, we are viewing both $(m,n)$-mixed graphs as labelled and thus are not considering equivalence under switching followed by an automorphism. Such an extension of equivalence is possible but unnecessary in this work. Since $\Gamma$ is a group, the following proposition is immediate.

**Proposition 1.1.** $\Gamma$-switch equivalence is an equivalence relation on the set of (labelled) $(m,n)$-mixed graphs.

We are now ready to define switching homomorphisms. Our definition naturally builds on homomorphisms of signed graphs \[8,14\] and push homomorphisms of digraphs [11]. Let $G$ and $H$ be $(m,n)$-mixed graphs. A $\Gamma$-switchable homomorphism of $G$ to $H$ is a sequence of switches $\Sigma$ together with a homomorphism $G^{\Sigma} \rightarrow H$. We denote the existence of such a homomorphism by $G \rightarrow_{\Gamma} H$, or $f : G \rightarrow_{\Gamma} H$ when we wish to name the mapping. Observe the notation $G \rightarrow H$ refers to a homomorphism of $(m,n)$-mixed graphs without switching, and $G \rightarrow_{\Gamma} H$ refers to switching $G$ followed by a homomorphism of (the resulting) $(m,n)$-mixed graphs.

A useful fact is the following. If $G \rightarrow_{\Gamma} H$, then $G \rightarrow_{\Gamma} H^{(v,\pi)}$ for any $v \in V(H)$ and any $\pi \in \Gamma$. To see this let $\Sigma$ be a sequence of switches such that $f : G^{\Sigma} \rightarrow H$. Let $X = f^{-1}(v) \subseteq V(G^{\Sigma})$. It is easy to see the same vertex mapping $f : V(G) \rightarrow V(H)$ defines a homomorphism $(G^{\Sigma})^{(X,\pi)} \rightarrow H^{(v,\pi)}$. As a result of this observation, we have two immediate corollaries. First, $\Gamma$-switchable
homomorphisms compose. Second, when studying the question “does $G$ admit a $\Gamma$-switchable homomorphism to $H$?”, we are free to replace $H$ with any $H'$ switch equivalent to $H$.

For (classical) graphs, $G$ is $k$-colourable if and only if it admits a homomorphism to a graph $H$ of order $k$. Analogously, we say an $(m,n)$-mixed graph $G$ is $\Gamma$-\textit{switchable} $k$-\textit{colourable}, if there is an $(m,n)$-mixed graph $H$ of order $k$ such that $G \twoheadrightarrow_{\Gamma} H$. The corresponding decision problem is defined as follows. Let $k \geq 1$ be a fixed integer and $\Gamma \leq S^m \times S^n \times S^2_n$ be a fixed group. We define the following decision problem.

\textbf{\textit{\Gamma-Switchable} $k$-\textit{Col}}

\textbf{Input:} An $(m,n)$-mixed graph $G$.

\textbf{Question:} Is $G$ $\Gamma$-switchable $k$-colourable?

Our main result is the following dichotomy result for $\Gamma$-\textit{Switchable} $k$-\textit{Col}.

\textbf{Theorem 1.2.} Let $k \geq 1$ be an integer and $\Gamma \leq S^m \times S^n \times S^2_n$ be a group. If $k \leq 2$, then $\Gamma$-\textit{Switchable} $k$-\textit{Col} is solvable in polynomial time. If $k \geq 3$, then $\Gamma$-\textit{Switchable} $k$-\textit{Col} is NP-hard.

The NP-hardness half of the dichotomy is immediate.

\textbf{Proposition 1.3.} For $k \geq 3$, $\Gamma$-\textit{Switchable} $k$-\textit{Col} is NP-hard.

\textit{Proof.} Let $G$ be an instance of $k$-colouring (for classical graphs). Let $G'$ be the $(m,n)$-mixed graph obtained from $G$ by assigning each edge colour 1. If $G$ is $k$-colourable, then clearly $G'$ is $k$-colourable. (Assign all edges in $G'$ and $K_k$ the colour 1 and use the same mapping.) Conversely, if $G'$ is $k$-colourable, then the $\Gamma$-switchable homomorphism induces a homomorphism of the underlying graphs showing $G$ is $k$-colourable. \hfill \Box

For an Abelian group we remark that if $G$ and $G'$ are switch equivalent, then there is a sequence of switches $\Sigma$ of length at most $|V(G)|$ so that $G^\Sigma = G'$. (This is discussed in more detail below.) Thus when $\Gamma$ is Abelian, $\Gamma$-\textit{Switchable} $k$-\textit{Col} is in NP, and we can conclude for $k \geq 3$, the problem is NP-complete. The situation for non-Abelian groups is more complicated and is studied further in \cite{3}.

It is trivial to decide if an $(m,n)$-mixed graph is 1-colourable. Thus to complete the proof we settle the case $k = 2$. Results are known when $\Gamma$ belongs to certain families of groups \cite{5,13}. The remainder of the paper establishes the problem is polynomial time solvable for all groups $\Gamma$.

We conclude the introduction with a remark on the general homomorphism problem. Let $H$ be a fixed $(m,n)$-mixed graph and $\Gamma$ a fixed permutation group.

\textbf{\textit{\Gamma-Hom-H}}

\textbf{Input:} An $(m,n)$-mixed graph $G$.

\textbf{Question:} Does $G$ admit a $\Gamma$-switchable homomorphism to $H$?

The complexity of $\Gamma$-\textit{Hom-H} has been investigated for the same families
of groups as Γ-switchable k-colouring in [5, 13]. The following theorem is an immediate corollary to our main result.

**Theorem 1.4.** Let \( H \) be a 2-colourable \((m, n)\)-mixed graph, then \( \Gamma \)-Hom-\( H \) is polynomial time solvable.

## 2 Restriction to \( m \)-edge coloured graphs

If a non-trivial \((m, n)\)-mixed graph \( G \) is 2-colourable, then the target of order 2 to which \( G \) maps must be a monochromatic \( K_2 \) or a monochromatic tournament \( T_2 \). In the former case \( G \) must have only edges and in the latter only arcs. Moreover, the underlying graph of \( G \) must be bipartite as a 2-colouring of \( G \) induces a 2-colouring of the underlying graph.

In this section we focus on the case where \( G \) has only edges and is bipartite. For ease of notation, and to align with the existing literature, we will refer to \( G \) as an \( m \)-edge coloured graph. Recall we use \([m]\) as the set of edge colours, and in this case we may restrict \( \Gamma \) to be a subgroup of \( S_m \). We let \( H \) be the \( m \)-edge coloured \( K_2 \) with its single edge of colour \( i \), and denote \( H \) by \( K^i_2 \).

We begin with some key observations. Let \( G \) be an \( m \)-edge coloured graph. If \( G \rightarrow_{\Gamma} K^i_2 \), then every colour appearing on an edge of \( G \) must belong to the orbit of \( i \) under \( \Gamma \); otherwise, \( G \) is a no instance. Therefore, we make the assumption that \( \Gamma \) acts transitively on \([m]\). Under this assumption \( K^i_2 \) is switch equivalent to \( K^j_2 \) for any \( j \in [m] \). Thus we have the following proposition.

**Proposition 2.1.** Fix \( i \in [m] \). Let \( G \) be a bipartite \( m \)-edge coloured graph. The following are equivalent.

1. \( G \rightarrow_{\Gamma} K^i_2 \),
2. \( G \rightarrow_{\Gamma} K^j_2 \) for any \( j \in [m] \),
3. \( G \) can be switched to be monochromatic of some colour \( j \).

**Proof.** The implication (1) \( \Rightarrow \) (2) follows from the fact that \( K^j_2 \rightarrow_{\Gamma} K^i_2 \) for any \( j \in [m] \) by the transitivity assumption. The implication (2) \( \Rightarrow \) (3) is trivial. Suppose \( G \) can be switched to be monochromatic of some colour \( j \). Let \( G \) have the bipartition \( X \cup Y \). Since \( \Gamma \) is transitive, there is \( \pi \in \Gamma \) such that \( \pi(j) = i \). Then \( G^{(X, \pi)} \) is monochromatic of colour \( i \) implying \( G \rightarrow_{\Gamma} K^i_2 \).

We have reduced the problem of determining whether an \( m \)-edge coloured graph \( G \) is 2-colourable to testing if \( G \) is bipartite and can be switched to be monochromatic of some colour \( j \).

In the case of signed graphs (2-edge colours), \( G \) can be switched to be monochromatic of colour \( j \) if and only if each cycle of \( G \) can be switched to be a monochromatic cycle of colour \( j \) [18]. We shall show the same result holds for bipartite \( m \)-edge coloured graphs. However, for our setting the question of when a cycle can be switched to be monochromatic is more complicated. Hence, we begin by characterizing when an \( m \)-edge coloured even cycle can be made...
monochromatic. To this end, let $G$ be a $m$-edge coloured cycle of length $2k$ on vertices $v_0, v_1, \ldots, v_{2k-1}, v_0$. By switching at $v_1$, the edge $v_0v_1$ can be made colour $i$. Next by switching at $v_2$, the edge $v_1v_2$ can be made colour $i$. Continuing, we see that $G$ can be switched so that all edges except $v_{2k-1}v_0$ are colour $i$. For $i, j \in [m]$, we say the cycle $G$ is nearly monochromatic of colours $(i, j)$ if $G$ has $2k-1$ edges of colour $i$ and 1 edge of colour $j$. Thus the problem of determining if an even cycle can be switched to be monochromatic is reduced to the problem of determining if a nearly monochromatic cycle of length $2k$ can be switched to be monochromatic.

Let $G$ be a cycle of length $2k$ that is nearly monochromatic of colours $(i, j)$. We define a relation on $[m]$ by $j \sim_{2k} i$ if $G$ is $\Gamma$-switchably equivalent to a monochromatic $C_{2k}$ of colour $i$ or equivalently $G \rightarrow^{\Gamma} K_2^i$.

As the definition suggests, the relation is an equivalence relation.

**Lemma 2.2.** The relation $\sim_{2k}$ is an equivalence relation.

**Proof.** The relation is trivially reflexive.

To see $\sim_{2k}$ is symmetric, assume $j \sim_{2k} i$. Let $G$ be a cycle of length $2k$ that is nearly monochromatic of colour $(j, i)$. Label the vertices of the cycle in the natural order as $v_0, v_1, \ldots, v_{2k-1}, v_0$ where $v_0v_{2k-1}$ is the unique edge of colour $i$. Suppose $\pi(j) = i$. Let $\Sigma = (v_1, \pi), (v_3, \pi), \ldots, (v_{2k-3}, \pi)$. Then $G\Sigma$ is nearly monochromatic of colour $(i, j)$, with edge $v_{2k-2}v_{2k-1}$ being the unique edge of colour $j$. By assumption there is a sequence of switches, say $\Sigma'$, so that $G\Sigma'\Sigma$ is monochromatic of colour $i$, giving $G \rightarrow^{\Gamma} K_2^i$. Thus, $G \rightarrow^{\Gamma} K_2^i$ by Proposition [2.1]. That is, $G$ can be made monochromatic of colour $j$ or $i \sim_{2k} j$.

To prove $\sim_{2k}$ is transitive, suppose $i \sim_{2k} j$ and $j \sim_{2k} l$. Let $G, G'$, and $G''$ be $m$-edge coloured cycles of length $2k$ each with the vertices $v_0, v_1, \ldots, v_{2k-1}$. (Technically, we are considering three distinct edge colourings of the same underlying graph.) Suppose $G, G'$, and $G''$ are nearly monochromatic of colours $(j, i)$, $(l, j)$, and $(l, i)$ respectively. There are $2k-1$ edges of colour $j$ in $G$ with edge $v_0v_{2k-1}$ of colour $i$ in $G$. Similarly there are $2k-1$ edges of colour $l$ in $G'$ with edge $v_0v_{2k-1}$ of colour $j$ in $G'$ and $2k-1$ edges of colour $l$ with edge $v_0v_{2k-1}$ of colour $i$ in $G''$. We shall show $G''$ can be switched to be monochromatic of colour $l$.

By hypothesis, there is a sequence $\Sigma'$ such that $G\Sigma'\Sigma$ is monochromatic of colour $l$. In particular, under $\Sigma'$ all edges of colour $l$ remain colour $l$, and the edge $v_0v_{2k-1}$ changes from $j$ to $l$. Thus, if we apply $\Sigma'$ to $G''$ the edges of colour $l$ remain colour $l$ and the product of those switches at $v_0$ and $v_{2k-1}$ changes $v_0v_{2k-1}$ from colour $i$ to colour $\sigma(i)$ for some $\sigma \in \Gamma$. We observe by the fact that $G\Sigma'\Sigma$ is monochromatic, $\sigma(j) = l$.

We now construct a modified inverse of $\Sigma'$. Let $\Sigma''$ be the subsequence of $\Sigma'$ consisting of the switches only at $v_0$ or $v_{2k-1}$. That is, $\Sigma''$ is a subsequence $(v_{s_0}, \pi_0), (v_{s_1}, \pi_1), \ldots, (v_{s_r}, \pi_r)$ where each $v_{s_r} \in \{v_0, v_{2k-1}\}$. Let $X$ (respectively $Y$) be the vertices of $G''$ with even (respectively odd) subscripts. Starting with $G\Sigma''$ apply the following sequence of switches. For $r = t, t-1, \ldots, 0$, if $v_s = v_0$, then apply the switch $(X, \pi_r^{-1})$; otherwise, $v_s = v_{2k-1}$ and apply the switch $(Y, \pi_r^{-1})$. The net effect is to apply $\sigma^{-1}$ to each edge of $G\Sigma''$. Thus
each edge of colour $l$ switches to $j$ and the edge $v_0v_{2k-1}$ of colour $\sigma(i)$ becomes colour $i$. That is, we can switch $G''$ to be $G$. By hypothesis, $G$ can be switched to be monochromatic of colour $j$. By Proposition 2.1 the resulting $m$-edge coloured graph can be switched to be monochromatic of colour $l$, i.e., $i \sim 2k$ $l$, as required.

We denote the equivalence classes with respect to $\sim 2k$ by $[i]_{\Gamma}^{2k} = \{ j | j \sim 2k \ i \}$. We now show that these classes are independent of cycle length (for even length cycles).

**Theorem 2.3.** Let $\Gamma \leq S_m$ and $i \in [m]$. Then $[i]_{\Gamma}^{2l} = [i]_{\Gamma}^{2k}$ for all $l, k \in \{2, 3, \ldots \}$.

**Proof.** Let $i \in [m]$ and let $k$ be an integer $k \geq 2$. We show $[i]_{\Gamma}^4 = [i]_{\Gamma}^{2k}$ from which the result follows.

Suppose $j \in [i]_{\Gamma}^4$. Let $G$ be a cycle of length $2k$ and $H$ a cycle of length 4 where both are nearly monochromatic of colours $(i, j)$. Since $G \to H$ and by hypothesis, $H \to \Gamma K_{\frac{2k}{2}}$, we have $G \to H \to \Gamma K_{\frac{2k}{2}}$ and thus $j \in [i]_{\Gamma}^{2k}$.

Conversely, suppose $j \in [i]_{\Gamma}^{2k+2}$. We will show $j \in [i]_{\Gamma}^{2k}$ from which we can conclude by induction that $j \in [i]_{\Gamma}^4$. Let $G$ be the $m$-edge coloured graph constructed as follows. Let $v_1, v_2, \ldots, v_k; u_1, u_2, \ldots, u_k$; and $w_1, w_2, \ldots, w_k$ be three disjoint paths of length $k - 1$. Join $v_1$ to both $u_1$ and $w_1$, and $v_k$ to both $u_k$ and $w_k$. Each edge is colour $i$ with the exception of $v_1u_1$ which is colour $j$. (Thus, $G$ is the $\theta$-graph with path lengths $k + 1, k - 1, k + 1$.) Denoted the cycles $u_1, \ldots, u_k, v_k, \ldots, v_1, u_1$ and $w_1, \ldots, w_k, v_k, \ldots, v_1, w_1$ by $C_1$ and $C_2$ respectively. Observe both have length $2k$, $C_1$ is nearly monochromatic of colours $(i, j)$ and $C_2$ is monochromatic of colour $i$. Finally, let $C_3$ be the cycle $u_1, \ldots, u_k, v_k, w_k, \ldots, w_1, v_1, u_1$. The cycle $C_3$ has length $2k + 2$ and is nearly monochromatic of colours $(i, j)$. See Figure 1.

By assumption there exists a sequence of switches $\Sigma$ (acting on the vertices of $C_3$) such that in $G^{\Sigma}$ the cycle $C_3$ is monochromatic of colour $i$. We note that
and $v_{k-1}v_k$ might not be of colour $i$ in $G^{\Sigma}$.

There is an automorphism $\varphi$ of the underlying graph $G$ that fixes each $v_l$, $l = 1, 2, \ldots, k$, and interchanges each $u_l$ with $w_l$. We apply $\Sigma^{-1}$ to $\varphi(G^{\Sigma})$ as follows. Let $\Sigma'$ be the sequence obtained from $\Sigma$ by reversing the order of the sequence, replacing each permutation with its inverse permutation and replacing all switches on vertices $u_l$ with switches on $w_l$ and vice versa. (Switches on $v_1$ and $v_k$ are applied to $v_1$ and $v_k$ respectively.) Then in $G^{\Sigma\Sigma'}$ we see that $C_1$ is monochromatic of colour $i$. Therefore $[i]_{\Gamma}^{2k} \supseteq [i]_{\Gamma}^{2k+2}$ for all $k \geq 2$. We conclude $[i]_{\Gamma}^4 = [i]_{\Gamma}^{2k}$ for all $k \geq 2$.

As the equivalence classes depends only on the group and not the length of the cycle, we henceforth denote these classes as $[i]_{\Gamma}$. If $j \in [i]_{\Gamma}$, we say $i$ can be $\Gamma$-substituted for $j$; that is, the single edge of colour $j$ in the cycle can be switched to colour $i$. We call $[i]_{\Gamma}$ the $\Gamma$-substitution class for $i$.

For a fixed $m$ and $\Gamma$, $[i]_{\Gamma}$ can be computed in constant time as there is a constant number of $m$-edge coloured 4-cycles, and a constant number of (single) switches that can be applied to these cycles, from which the equivalence classes can be computed using the transitive closure.

**Theorem 2.4.** Let $G$ be an $m$-edge coloured $C_{2k}$. It can be determined in polynomial time whether there is a $\Gamma$-switchable homomorphism of $G$ to $K_2^i$.

**Proof.** As described above, we can switch $G$ to be nearly monochromatic of colours $(i, j)$, for some $j$. Then $G \rightarrow_{\Gamma} K_2^i$ if and only if $j \in [i]_{\Gamma}$. Testing this condition can be done in constant time.

We now show the $\Gamma$-Hom-$K_2^i$ problem is polynomial time solvable. This is accomplished by showing the problem of determining whether a given $m$-edge coloured bipartite graph can be made monochromatic of colour $i$ is polynomial time solvable.

We begin with the following observation that trees can always be made monochromatic.

**Lemma 2.5.** Let $T$ be a $m$-edge coloured tree, then for any $\Gamma$, $T \rightarrow_{\Gamma} K_2^i$.

**Proof.** Let $T$ be a $m$-edge coloured tree. Let $v_1, v_2, \ldots, v_{|T|}$ be a depth first search ordering of $T$ rooted at $v_1$. For each $k \in 2, \ldots, |T|$, switch at $v_k$ so that the edge from $v_k$ to its parent in the depth first search ordering has colour $i$. We observe that if the subtree $T[v_1, \ldots, v_{k-1}]$ is monochromatic of colour $i$, then after switching at $v_k$, so is the subtree $T[v_1, \ldots, v_k]$.

Let $G$ and $H$ be $m$-edge coloured graphs such that $H$ is a subgraph of $G$. A retraction from $G$ to $H$, is a homomorphism $r : G \rightarrow H$ such that $r(x) = x$ for all $x \in V(H)$. We shall use the following result of Hell [9].

**Theorem 2.6.** Let $G$ be a bipartite graph. Suppose $P$ is a shortest path from $u$ to $v$ in $G$. Then $G$ admits a retraction to $P$. 

We now show, for general \(m\)-edge coloured graphs \(G\), testing if \(G \to_{\Gamma} K_2^i\) comes down to testing if each cycle admits a \(\Gamma\)-switchable homomorphism to \(K_2^i\). To this end define \(C(G)\) to be the set of cycles in an \(m\)-edge coloured graphs \(G\), and \(\mathcal{F}_\Gamma\) to be the collection of cycles \(C\) such that \(C \not\to_{\Gamma} K_2^i\).

**Theorem 2.7.** Let \(G\) be a connected \(m\)-edge coloured graph and \(\Gamma\) a transitive group acting on \([m]\). Suppose \(i \in [m]\). The following are equivalent.

1. \(G \to_{\Gamma} K_2^i\).
2. For all cycles \(C \in C(G)\), \(C \to_{\Gamma} K_2^i\).
3. \(G\) is bipartite and for any spanning \(T\) of \(G\), there is a switching sequence \(\Sigma\) such that in \(G^\Sigma\), \(T\) is monochromatic of colour \(i\) and for each cotree edge the colour \(i\) can be \(\Gamma\)-substituted for the colour of the cotree edge.
4. For all cycles \(C \in \mathcal{F}_\Gamma\), \(C \not\to_{\Gamma} G\)

**Proof.** We first prove the equivalence of statements (1), (2), and (3).

(1) \(\Rightarrow\) (2) is trivially true.

(2) \(\Rightarrow\) (3). We first observe that \(G\) must be bipartite as all cycles in the underlying graph map to \(K_2\). Let \(T\) be a spanning tree in \(G\) and let \(\Sigma\) be the switching sequence constructed as in the proof of Lemma 2.5. Then \(T\) is monochromatic of colour \(i\) in \(G^\Sigma\). Let \(e\) be a cotree edge of colour \(j\). The fundamental cycle \(C_e\) in \(T + e\) is nearly monochromatic of colours \((i, j)\). By hypothesis \(C \to_{\Gamma} K_2^i\). Hence, \(i\) \(\Gamma\)-substitutes for \(j\).

(3) \(\Rightarrow\) (1). As above, let \(T\) be a spanning tree that is monochromatic of colour \(i\) in \(G^\Sigma\). Let \(e_1, e_2, \ldots, e_k\) be an enumeration of the cotree edges of \(T\). By hypothesis for each cotree edge \(e_i\), its colour, say \(j\) (in \(G^\Sigma\)) belongs to \([i]\Gamma\).

Let \(T + \{e_1, \ldots, e_t\}\) be the subgraph of \(G^\Sigma\) induced by the edges \(E(T) \cup \{e_1, \ldots, e_t\}\). Clearly \(T \to_{\Gamma} K_2^j\). Suppose \(T + \{e_1, \ldots, e_{t-1}\} \to_{\Gamma} K_2^j\). Let \(e_t = uv\) have colour \(j\). Let \(P\) be a shortest path from \(u\) to \(v\) in \(T + \{e_1, \ldots, e_{t-1}\}\). By [9], there is a retraction \(r : T + \{e_1, \ldots, e_{t-1}\} \to P\) with \(r(u) = u\) and \(r(v) = v\). Adding the edge \(e_t\) shows \(T + \{e_1, \ldots, e_t\} \to_{\Gamma} P + e_t\) where \(P + e_t\) is a nearly monochromatic cycle of colours \((i, j)\). By assumption \(i\) \(\Gamma\)-substitutes for \(j\), so \(P + e_t \to_{\Gamma} K_2^i\) and by composition \(T + \{e_1, \ldots, e_t\} \to_{\Gamma} K_2^i\). By induction, \(G \to_{\Gamma} K_2^i\).

Finally, we show (1) and (4) are equivalent. If there is \(C \in \mathcal{F}_\Gamma\) such that \(C \to_{\Gamma} G\), then \(G \not\to_{\Gamma} K_2^i\). Conversely, if \(G \not\to_{\Gamma} K_2^i\), then by (2), there is a cycle \(C\) in \(G\) such that \(C \not\to_{\Gamma} K_2^i\). In particular, \(C \in \mathcal{F}_\Gamma\) and the inclusion map gives \(C \to_{\Gamma} G\).

Given an \(m\)-edge coloured graph \(G\), it is easy to test condition (3) for each component. Checking \(G\) is bipartite and the switching of a spanning forest can be done in linear time in \(|E(G)|\). The look up for each cotree edge requires constant time.

However, the theorem actually gives us a certifying algorithm which we now outline (under the assumption \(G\) is connected). First test if \(G\) is bipartite. If it is
not, then we discover an odd cycle certifying a no instance. Otherwise construct a spanning tree, and switch so that the tree is monochromatic of colour \( i \). Either the colour of each cotree edge belongs to \([i]_{i^*}\) or we discover a cotree edge that does not. In the latter case we have a cycle of \( C \in F_\Gamma \) that certifies \( G \) is a no instance.

Thus assume all cotree edges have colours in \([i]_{i^*}\). The proof of Theorem 2.7 provides an algorithm for switching \( G \) to be monochromatic of colour \( i \) through lifting the switching of the retract \( P + e_i \) to all of \( G \). We show how using a similar idea with \( C_4 \) also works and gives a clearer bound on the running time. Let \( j \) be the colour of a cotree edge, say \( uv \). Recall \( j \in [i]_{i^*} \). Let \( H \) be a \( C_4 \) with vertices labelled as \( v_0, v_1, v_2, v_3 \) and edges coloured as \( v_0v_3 \) is colour \( j \) and all other edges are colour \( i \). Let \( \Sigma \) be a switching sequence so that \( H^{\Sigma} \) is monochromatic of colour \( i \). Let \( X \) (respectively \( Y \)) be the vertices of \( G \) in the same part of the bipartition as \( u \) (respectively \( v \)). For each \((v_i, \pi_i)\) in \( \Sigma \) we apply the same switch \( \pi_i \) in \( G \) at \( u \) if \( v_i = v_0 \); at \( X \setminus \{u\} \) if \( v_i = v_2 \); at \( v \) if \( v_i = v_3 \); and at \( Y \setminus \{v\} \) if \( v_i = v_1 \). At the end of applying all switches in \( \Sigma \), edges in \( G \) that were of colour \( i \) remain colour \( i \), and the cotree edge \( uv \) switches from \( j \) to \( i \). As \(|\Sigma|\) is constant (in \(|\Gamma|\)), this switching sequence for \( uv \) requires \( O(|V(G)|) \) switches. In this manner the concatenation of \(|E(G)| - |V(G)| + 1\) such switching sequences (together with the switches required to make \( T \) monochromatic) switch \( G \) to be monochromatic of colour \( i \). This sequence together with the bipartition of \( G \) certifies that \( G \rightarrow \Gamma K^i_2 \). We have the following.

Corollary 2.8. The problem \( \Gamma\)-HOM-\( K^i_2 \) is polynomial time solvable by a certifying algorithm.

3 General \((m, n)\)-coloured graphs

In this section we show the \( \Gamma\)-2-Col problem is polynomial time solvable. As noted above, a general \((m, n)\)-mixed graph \( G \) is 2-colourable if it only has edges and for some edge colour \( i \), \( G \rightarrow \Gamma K^i_2 \) or it only has arcs and for some arc colour \( i \), \( G \rightarrow \Gamma T^i_2 \). Having established the \( \Gamma\)-HOM-\( K^i_2 \) problem is polynomial time solvable, we now show \( \Gamma\)-HOM-\( T^i_2 \) polynomially reduces to \( \Gamma\)-HOM-\( K^i_2 \). This establishes the polynomial time result of Theorem 1.2 which we restate.

Theorem 3.1. The \( \Gamma\)-Switchable 2-Col problem is polynomial time solvable.

Proof. Let \( G \) be an instance of \( \Gamma\)-Switchable 2-Col, i.e., an \((m, n)\)-mixed graph. If \( G \) is not bipartite, we can answer No. If \( G \) has both edges and arcs, then we can answer No. If \( G \) only has edges, then by Corollary 2.8 we can choose any edge colour \( i \) (we still assume \( \Gamma \) is transitive) and test \( G \rightarrow \Gamma K^i_2 \) in polynomial time.

Thus assume \( G \) is bipartite with bipartition \((A, B)\) and has only arcs. Analogous to Section 2 we can view \( \Gamma \) as acting transitively on the \( n \)-arc colours. If \( \Gamma \) does not allow any arc colours to switch direction, i.e., for all \( \pi \in \Gamma \), \( \gamma_i(uv) = uv \) for all \( i \), then \( G \) must have all its arcs from say \( A \) to \( B \); otherwise, we can say
follows. For each arc colour $i,j \in \text{an edge } uv \in G$ acts on $(C$ that changes one into the other. (The existence of inverses ensures this is an edge-colouring of $C$.)

We now construct a $(2n)$-edge coloured graph $G'$ as follows. Let $V(G') = V(G)$. If there is an arc of colour $i$ from $u \in A$ to $v \in B$, we put an edge $uv$ of colour $i^+$ in $G'$, and if there is an arc of colour $i$ from $v \in B$ to $u \in A$, we put an edge $uv$ of colour $i^−$ in $G'$.

From $\Gamma$ we construct a new group $\Gamma' \leq S_{2n}$. Note that $\Gamma$ as described above acts on $(m,n)$-mixed graphs and $\Gamma'$ will be naturally restricted to acting on $(2n)$-edge coloured graphs. Let $\pi = (\alpha, \beta, \gamma_1, \ldots, \gamma_n) \in \Gamma$. Define $\pi' \in \Gamma'$ as follows. For each arc colour $i$,

$$\pi'(i^+) = \begin{cases} \beta(i)^+ & \text{if } \gamma_i(uv) = uv \\ \beta(i)^− & \text{if } \gamma_i(uv) = vu \end{cases} \quad \text{and} \quad \pi'(i^−) = \begin{cases} \beta(i)^− & \text{if } \gamma_i(uv) = uv \\ \beta(i)^+ & \text{if } \gamma_i(uv) = vu \end{cases}$$

It can be verified that the mapping $\pi \to \pi'$ is a group isomorphism.

The translation of $G$ to $G'$ can be expressed as a function $F(G) = G'$. It is straightforward to verify $F$ is a bijection from $n$-arc coloured graphs to $2n$-edge coloured graphs provided we fix the bipartition $V(G) = A \cup B$. Moreover, if $\pi \in \Gamma$ and $\pi'$ is the resulting permutation in $\Gamma'$, then again it is easy to verify that $F(G(v,\pi)) = (G'(v,\pi'))$ for any $v$ in $V(G) = V(G')$.

Suppose $G \to_{\Gamma} T_2^3$. By the transitivity of $\Gamma$, we may assume that $T_2^3$ has its tail in $A$, and thus all arcs in $G$ can be switched to be colour $i$ with their tail in $A$. The corresponding switches on $G'$ switch all edges to colour $i^+$. That is, $G' \to_{\Gamma'} K_2^+$. On the other hand, if $G' \to_{\Gamma'} K_2^+$, then the corresponding switches on $G$ show that $G \to_{\Gamma} T_2^3$ (with the vertices of $A$ mapping to the tail of $T_2^3$).

We conclude this section with a remark on the number of switches required to change the input $G$ to be monochromatic. There are $|V(G)|−1$ switches required to change a spanning tree of $G$ to be monochromatic of colour $i$. To change the cotree edges to colour $i$ (assuming each is of a colour in $[i]_\Gamma$), we claim at most $c_\Gamma|V(G)|$ switches are required where $c_\Gamma$ is a constant depending on $\Gamma$ and the number of colours ($m$ and $n$). We argue only for $m$-edge coloured graphs, given the reduction above. For (a labelled) $C_4$, there are $m^d$ edge colourings. For each vertex there are $|\Gamma|$ switches. The reconfiguration graph $\mathcal{C}$ has a vertex for each edge-colouring of $C_4$ and an edge joining two vertices is there is a single switch that changes one into the other. (The existence of inverses ensures this is an undirected graph.) Thus, $\mathcal{C}$ has order $m^d$ and is regular of degree $|\Gamma|$. Given $j \in [i]_\Gamma$, there is a path in $\mathcal{C}$ from a nearly monochromatic $C_4$ of colours $(i,j)$ to a monochromatic $C_4$ of colour $i$. The switches on this path can be lifted to $G$ so that the spanning tree remains of colour $i$ and the cotree edge switches to
The total number of switches is at most max\{diam(C')\} \cdot |V(G)| where $C'$ runs over all components of $C$. Thus we have the following.

**Proposition 3.2.** Let $G$ be a $m$-edge coloured bipartite graph. Let $\Gamma$ be a group acting transitively on $[m]$. If $G$ is $\Gamma$-switch equivalent to a monochromatic graph, then the sequence $\Sigma$ of switches which transforms $G$ to be monochromatic satisfies,

$$|\Sigma| \leq |V(G)| - 1 + c_\Gamma |V(G)||E(G)| - |V(G)| + 1$$

where $c_\Gamma$ depends only on $\Gamma$ and $m$.

In the case that $\Gamma$ is abelian, the switches in $\Sigma$ can be reordered, then combined, so that each vertex is switched only once.

4 Conclusion

We have established a dichotomy for the $\Gamma$-Switchable $k$-Col problem. This is a step in obtaining a dichotomy theorem for $\Gamma$-Hom-$H$ for all $(m,n)$-mixed graphs $H$ and all transitive permutation groups $\Gamma$. Work towards a general dichotomy is the focus of our companion paper [3].
