Consider a spectrally negative Lévy process with unknown diffusion coefficient and Lévy measure and suppose that the high frequency trading data is given. We use the techniques of threshold estimation and regularized Laplace inversion to obtain the estimator of survival probability for a spectrally negative Lévy process. The asymptotic properties are given for the proposed estimator. Simulation studies are also given to show the finite sample performance of our estimator.

1. Introduction

In actuarial science, it is an important topic to consider the ruin probability for some risk models. There are some methods for this topic, for example, the integro-differential equation technique, renewal theory, Laplace transform, martingale theory, and so on. For details, see the monograph of Asmussen and Albrecher [1]. These methods heavily depend on the knowledge of the risk model, which are usually unknown in practice. It is also known that explicit formula for the ruin probability is usually not available when we have no precise information on the risk model. In order to overcome this difficulty, many researchers have done a large amount of work and obtained lots of nice results. Some authors have considered the approximations, upper and lower bounds of the ruin probability. See, for example, Dufresne and Gerber [2], Veraverbeke [3], Dermizakis and Politis [4], and Li et al. [5]. Others have been contributed to semiparametric and nonparametric estimation of the ruin probability. See, for example, Croux and Veraverbeke [6], Frees [7], Mnatsakanov et al. [8], Pitts [9], Politis [10], You et al. [11], and Zhang et al. [12].

In practical situations, to get the data is much easier than to obtain the precise information on the risk model. In financial market, high frequency trading exists and a lot of high frequency trading data can be used to make statistical inference of the law of financial market. Using the data, we can estimate the survival probability by some statistical methods. In our work, we assume that the high frequency data is from \( n \) discrete time observations with step \( h_n \). The asymptotic framework is that \( n \) tends to infinity and \( h_n \) tends to zero while \( nh_n \) tends to infinity. See, Comte and Genon-Catalot [13, 14]. For an insurance company, if the surplus has lots of small fluctuations, we assume that the surplus may be described by Lévy process. Our work will consider the survival probability for Lévy process. There are also some nice results for the ruin probability in Lévy process. For example, Zhang and Yang [15] have proposed a nonparametric estimator of ruin probability for pure jump Lévy process by Fourier (inversion) transform. The method of Zhang and Yang [15] has also been used by Shimizu and Zhang [16] to study the Gerber–Shiu function for Lévy subordinator. You and Cai [17] and Cai et al. [18] have constructed an estimator for the survival probability in a spectrally negative Lévy risk model by the regularized Laplace inversion technique. In the paper, we will use a threshold technique to study the survival probability. Mancini [19], Mancini [20], Shimizu [21], and Shimizu [22] have proposed the threshold technique for identifying the times when jumps larger than a suitably defined threshold occurred. Given a discrete record of observations, the technique may separate the contributions of the diffusion part and jump part of the risk model. Therefore, we can obtain more accurate data for the jump part of the risk
model by the threshold technique. In this paper, we will give an estimator of the survival probability by the threshold technique and the regularized Laplace inversion technique. Our method will calculate the survival probability more accurately for a spectrally negative Lévy risk model.

Here is a brief outline of this paper. We will introduce our risk model and define the survival probability in Section 2. In Section 3, we will construct an estimator of survival probability for our risk model. Section 4 gives the asymptotic properties of the estimators. In Section 5, we will do some simulations to show the finite sample size performance of the estimators. Finally, some conclusions are given in Section 6. All the technical proofs are presented in Appendix.

2. Preliminaries

2.1. Risk Model. Let

\[ Y_t = ct + \sigma W_t - J_t, \quad t \geq 0 \]  \hspace{1cm} (1)

be a spectrally negative Lévy process, where \( c > 0, \sigma > 0 \), and \( W = \{W_t, t \geq 0\} \) is a standard Brownian motion; \( J = \{J_t, t \geq 0\} \) is a subordinator; Suppose that \( W \) and \( J \) are independent of each other.

The Laplace exponent of \( Y = \{Y_t, t \geq 0\} \) is denoted by

\[ \psi_Y(s) = \frac{1}{t} \ln \left( E \left[ e^{Y_t} \right] \right) \]

\[ = cs + \frac{1}{2} \sigma^2 s^2 - \int_0^{\infty} (1 - e^{-sx}) \nu(dx), \quad s > 0, \]  \hspace{1cm} (2)

where \( \nu \) is a Lévy measure and satisfies \( \int_0^{\infty} (1 \wedge x) \nu(dx) < \infty \).

Let \( u > 0 \) be the initial surplus of an insurance company. The surplus at time \( t \) is given by

\[ U_t = u + Y_t = u + ct + \sigma W_t - J_t, \quad t \geq 0, \]  \hspace{1cm} (3)

where \( c \) is the rate of premium; \( \sigma \) represents the diffusion coefficient; and \( J \) and \( W \) denote the cumulative claims amount and a diffusion process.

2.2. Survival Probability. The infinite-time horizon survival probability \( \Phi(u) \) is defined as follows:

\[ \Phi(u) = 1 - \mathbb{P} \left( \inf_{0 \leq t < \infty} U_t \leq 0 \mid U_0 = u \right). \]  \hspace{1cm} (4)

In [23], Huzak et al. have given the following Pollaczek–Khinchin type formula for the survival probability,

\[ \Phi(u) = \left( 1 - \frac{\mu_1}{c} \right) \int_0^{\infty} \rho \left( G^{(1+)} * H^{(1)}(u) \right)(x), \quad u > 0, \]  \hspace{1cm} (5)

where \( \mu_1 = \int_0^{\infty} x \nu(dx), \quad H(x) = (1/\mu_1) \int_x^{\infty} \nu(x, \infty)dy \) and \( G \) is determined by the Laplace transform

\[ \int_0^{\infty} e^{-sx} dG(x) = \frac{c}{c + (\sigma^2/2)s}. \]  \hspace{1cm} (6)

By (5), the Laplace transform of \( \Phi(u) \) is given by

\[ \mathcal{L}_\Phi(s) = \int_0^{\infty} e^{-su} \Phi(u) du \]

\[ = \frac{c - \mu_1}{cs + (\sigma^2/2)s^2 - \int_0^{\infty} (1 - e^{-sx}) \nu(dx)}, \quad s > 0. \]  \hspace{1cm} (7)

3. Estimation of Survival Probability

In our work, we assume that \( \sigma \) and \( \nu \) are unknown. In order to estimate \( \Phi(u) \), we need to estimate the Laplace transform of \( \Phi(u) \). Now, let us rewrite (7) as follows:

\[ \mathcal{L}_\Phi(s) = \frac{1 - \rho}{(1/c)\psi_Y(s)}, \quad s > 0, \]  \hspace{1cm} (8)

where \( \rho = \mu_1/c \) and \( \psi_Y(s) = cs + (1/2)\sigma^2 s^2 - \int_0^{\infty} (1 - e^{-sx}) \nu(dx) \).

Suppose that a discrete sample \( Y^n = \{Y^n_i \mid t^n_i = ih_n; i = 0, 1, 2, \ldots, n\} \) can be observed. Let \( Z_i = Y^n_i - Y^n_{i-1} \) and \( h_n = t^n_i - t^n_{i-1} \) > 0. Our interest is to estimate \( \Phi(u) \) by a sample \( \{Z_1, Z_2, \ldots, Z_n\} \).

3.1. A Threshold Estimator of \( \mathcal{L}_\Phi(s) \). In this part, we will construct an estimator of \( \mathcal{L}_\Phi(s) \). If we can estimate \( \rho \) and \( \psi_Y(s) \) in (8), the estimator of \( \mathcal{L}_\Phi(s) \) will be given by a plug-in device. By You and Cai [17], an estimator of \( \psi_Y(s) \) has been given by

\[ \hat{\psi}_Y(s) = \frac{1}{h_n} \left( \sum_{k=1}^{n} e^{Z_k} - 1 \right), \quad s > 0. \]  \hspace{1cm} (9)

Now, the following work is to estimate \( \rho = \mu_1/c \). By Shimizu [21, 22], we introduce the filter which is defined by

\[ \mathcal{D}_k^n = \{ \omega \in \Omega; (ch_n - Z_k) > h_n^b \}, \]

\[ \mathcal{G}_k^n = \{ \omega \in \Omega; (ch_n - Z_k) \leq h_n^b \}, \]  \hspace{1cm} (10)

where \( b \) is a positive constant.

In Shimizu [21], the author assumed that \( J = \{J_t, t \geq 0\} \) is a compound Poisson process. When \( b \in (0, (1/2)) \), it is easy to judge a jump occurred if \( (ch_n - Z_k) > h_n^b \). As a result, \( (ch_n - Z_k) \) can be an approximation of the jump size when \( (ch_n - Z_k) > h_n^b \) and \( h_n \longrightarrow 0 \).

When \( J = \{J_t, t \geq 0\} \) is a compound Poisson process, we can give the following estimator of \( \rho \):

\[ \hat{\rho} = \frac{1}{c h_n} \sum_{k=1}^{n} (ch_n - Z_k) I_{\mathcal{G}_k^n}. \]  \hspace{1cm} (11)

If \( J = \{J_t, t \geq 0\} \) has possibly a infinite number of jumps in each finite time interval, we still choose \( \hat{\rho} \) as an estimator of \( \rho \).

Finally, by (8), (9), and (11), an estimator of \( \mathcal{L}_\Phi(s) \) is given by

\[ \hat{\mathcal{L}}_\Phi(s) = \frac{1 - \hat{\rho}}{(1/c)\hat{\psi}_Y(s)}, \quad s > 0. \]  \hspace{1cm} (12)
3.2. A Regularized Laplace Inversion Technique. In [24], Chauveau et al. have given the following regularized Laplace inversion technique.

**Definition 1.** Let \( m > 0 \) be a constant. The regularized Laplace inversion \( L_m^{-1} : L^2(0, \infty) \rightarrow L^2(0, \infty) \) is given by

\[
L_m^{-1} g(t) = \frac{1}{\pi} \int_0^\infty \int_0^\infty \Psi_m(y) y^{-1/2} e^{-ty} g(v) dv dy, \tag{13}
\]

for a function \( g \in L^2(0, \infty) \) and \( t \in (0, \infty) \), where

\[
\Psi_m(y) = \int_0^\infty \cosh(\pi x)\cos(x \log y) dx, \tag{14}
\]

and \( a_m = \pi^{-1} \cosh^{-1}(\pi m) > 0 \).

By Definition 1, the regularized Laplace inversion technique is available for any \( L^2(0, \infty) \) functions. According to the proof of Proposition 3.3 in You and Cai [17], we know that \( \tilde{L}_\Phi \) if \( L^2(0, \infty) \). In order to apply Definition 1, we must amend \( \tilde{L}_\Phi \).

Let \( \Phi_m(u) = e^{-\mu u} \Phi(u) \) for arbitrary fixed \( \theta > 0 \). Obviously, we have

\[
\tilde{L}_\Phi(s) = L_m^{-1} \tilde{L}_\Phi(s), \quad s > 0. \tag{15}
\]

Therefore, we will give an estimator of \( \tilde{L}_\Phi(s) \) as follows:

\[
\Phi_m(u) = e^{\mu u} \tilde{L}_m^{-1} L\Phi(s), \quad u > 0, \quad \theta > 0, \tag{17}
\]

for suitable \( m > 0 \).

4. Asymptotic Property of Estimators

In this section, we will study the asymptotic property for those estimators which are proposed in Section 3. In [17], You and Cai have given the asymptotic normality and consistency of \( \Phi(s) \). The following work will construct an estimator of \( \Phi(u) \) as follows:

\[
\hat{\Phi}_m(u) = e^{\mu u} \tilde{L}_m^{-1} L\Phi(s), \quad u > 0, \quad \theta > 0, \tag{17}
\]

for suitable \( m > 0 \).

5. Simulation

In this section, we will give some simulation studies to show the performance of our estimator with finite samples. The work is based on MATLAB. We do not pretend to find an optimal threshold function for each considered model.

We assume that the Lévy measure is given by \( \nu(dx) = \lambda (1/\eta) e^{-g(x)} dx \), then \( J \) is a compound Poisson process where the Poisson intensity is \( \lambda \) and the individual claim sizes are exponentially distributed with mean \( \eta \).

The survival probability is given by

\[
\Phi(u) = 1 - \frac{r_2 + (1/\eta) + (2\lambda \eta / \sigma^2)}{r_2 - r_1}, \tag{25}
\]

where \( r_2 < r_1 < 0 \) are negative roots of the following equation

\[
\frac{1}{2} \sigma^2 s + c - \frac{\lambda}{s + (1/\eta)} = 0. \tag{26}
\]

We take \( c = \lambda = 10, \quad \eta = 1/2, \quad \sigma = 5, \quad b = 1/4, \) and \( h_n = n^{-4/5} \). Then, \( \mu_1 = \lambda \eta = 5 \) and \( \rho = \mu_1 / c = 0.5 \).
First of all, we consider $\rho$. In Figure 1, we plot the mean points with sample sizes $n = 1000, 5000, 8000, 10000,$ and $30000$, which are computed based on 5000 simulation experiments.

In Table 1, we give the data of $\rho$ and its errors with sample sizes $n = 1000, 5000, 8000, 10000,$ and $30000$.

Now, we consider the estimator of $\psi_Y$. In Figure 2, we plot the mean points with sample sizes $n = 500, 1000, 5000, 8000, 10000,$ and $30000$, which are computed based on 5000 simulation experiments.

Next, we consider the estimator of $L\Phi_\theta$ with $\theta = 0.075$. In Figure 3, we plot the mean points with sample sizes $n = 5000, 10000, 30000, 50000,$ and $80000$, which are computed based on 5000 simulation experiments.

By Figure 3, the estimator $L\Phi_\theta$ is very close to the actual data of $L\Phi_\theta$ as $n \geq 30000$. Thus, we will use the same method as of Cai et al. [18] and You and Cai [17] to simulate $\Phi(u)$. In order to improve computational efficiency, we define

$$\Phi_\theta(u) = \left(e^{u\theta}/\alpha^3\right) \int_0^\infty \int_0^\infty e^{-usy} \left(\mathcal{M}_{\Phi_\theta}(s)\right)_{r_n} \psi_\theta(y) y^{-1/2} ds dy,$$  

(27)

where \( \left(\mathcal{M}_{\Phi_\theta}(s)\right)_{r_n} = 1 - (1/n_0h_{\theta}) \sum_{k=1}^{n_0} (ch_{\theta} - Z_k)I_{\mathbb{R}^+}^{n_0}/(1/ch_{\theta})(1/n_0) \sum_{k=1}^{n_0} e^{2Z_k} - 1), \)

$\frac{0.485}{0.49}$  

$\frac{0.49}{0.495}$  

$\frac{0.5}{0.505}$  

$\frac{0.51}{0.515}$  

$y$  

Figure 1: $\hat{\rho}$ with sample sizes $n = 1000, 5000, 8000, 10000,$ and $30000$.

Table 1: The data of $\hat{\rho}$ and its errors.

| Sample sizes | The data of $\hat{\rho}$ | The actual data of $\rho$ | Errors |
|--------------|--------------------------|---------------------------|--------|
| $n = 1000$   | 0.4878                   | 0.5                       | 0.0122 |
| $n = 5000$   | 0.4876                   | 0.5                       | 0.0124 |
| $n = 8000$   | 0.5033                   | 0.5                       | 0.0033 |
| $n = 10000$  | 0.5019                   | 0.5                       | 0.0019 |
| $n = 30000$  | 0.4989                   | 0.5                       | 0.0011 |

Figure 2: The estimator of $\psi_Y$ with sample sizes $n = 500, 1000, 5000, 8000, 10000,$ and $30000$. 
Ψ_p(y) = \int_a^\infty \cosh(\pi x) \cos(x \log(y)) \, dx \quad \text{and} \quad a_p = \pi^{-1} \cosh^{-1}(\pi p) > 0, \text{ and } n_0 = 30000.

Now, we will show the performance of \( \Phi_p(u) \).

In Figure 4, we plot the mean points with sample sizes \( n = 30000 \) and \( p = 100, 500, 800, 1000, \) and 3000, which are computed based on 5000 simulation experiments.

### 6. Conclusion

In this paper, we use the threshold estimation technique and regularized Laplace inversion technique to construct an estimator of survival probability for a spectrally negative Lévy process. The rate of convergence for the estimator is a logarithmic rate. We adopt a method which is proposed in Cai et al. [18] to improve the speed in simulated calculation. The further work is to improve the speed of convergence for the estimator. We will combine the threshold estimation technique with the Fourier transform (inversion) technique, Fourier cosine series expansion method, and Laguerre series expansion method to construct an estimator of survival probability. These methods can be referred to Zhang and Hu [12, 25], Zhang and Su [26, 27], Yu et al. [28], and so on. We hope some further studies will be performed for the risk model with the barrier or threshold dividend strategy. See, e.g., Peng et al. [29] and Yu et al. [30]. The Gerber–Shiu function and the aggregate dividends up to ruin will be estimated by some statistical methods.

### Appendix

#### The proof of Theorem 1

Proof. First of all, we have
\[ \sqrt{nh_n}(\tilde{\rho} - \rho) = \sqrt{nh_n}\left( \frac{1}{cnh_n} \sum_{k=1}^{n} (ch_n - Z_k)I_{\{\Delta_k^N \geq \lambda \mu/c\}} \right) \]

\[ = \sqrt{nh_n}\left( \frac{1}{cnh_n} \sum_{k=1}^{n} (ch_n - Z_k)I_{\{\Delta_k^N \geq \lambda \mu/c\}} - \frac{1}{cnh_n} \sum_{k=1}^{n} \mu Y_k I_{\{\Delta_k^N \geq 2\}} + \frac{1}{cnh_n} \sum_{k=1}^{n} \mu Y_k I_{\{\Delta_k^N \geq 2\}} - \frac{\lambda \mu}{c} \right) \]

\[ = \frac{1}{c \sqrt{nh_n}} \sum_{k=1}^{n} (ch_n - Z_k)I_{\{\Delta_k^N \geq 0\}} + \frac{1}{c \sqrt{nh_n}} \sum_{k=1}^{n} ((ch_n - Z_k)I_{\{\Delta_k^N \geq 2\}} - \mu Y_k I_{\{\Delta_k^N \geq 2\}}) I_{\{\Delta_k^N \geq 2\}} \]

\[ + \sqrt{nh_n}\left( \frac{1}{cnh_n} \sum_{k=1}^{n} \mu Y_k I_{\{\Delta_k^N \geq 2\}} \right). \tag{A.1} \]

Let us now deal with the first term of (A.1),

\[ P\left( \frac{1}{c \sqrt{nh_n}} \sum_{k=1}^{n} (ch_n - Z_k)I_{\{\Delta_k^N \geq 0\}} \neq 0 \right) \]

\[ \leq P\left( \bigcup_{k=1}^{n} \{(ch_n - Z_k) > h_n^b, \Delta_k^N = 0\} \right) \]

\[ \leq P\left( \sup_k (ch_n - Z_k)I_{\{\Delta_k^N = 0\}} > h_n^b \right) \tag{A.2} \]

\[ \leq P\left( \sup_k \sigma(W_{\psi}^t - W_{\psi}^{t-1}) > h_n^b \right) \]

\[ \leq \sum_k P\left( \sigma(W_{\psi}^t - W_{\psi}^{t-1}) > h_n^b \right). \]

By Proposition 3.2 and Corollary 3.3 in Mancini [19],

\[ \sum_k P\left( \sigma(W_{\psi}^t - W_{\psi}^{t-1}) > h_n^b \right) \leq 2n e^{-h_n^b(1/2\sigma^2) \psi} = 2n e^{-h_n^b(1/2\sigma^2) \psi}. \tag{A.3} \]

Because of \( b \in (0, (1/2)) \),

\[ 2n e^{-h_n^b(1/2\sigma^2) \psi} \rightarrow 0 \text{ as } n \rightarrow \infty. \]

Thus, the first term tends to zero in probability.

The second term of (A.1) tends to zero in probability, since

\[ P\left( \frac{1}{c \sqrt{nh_n}} \sum_{k=1}^{n} ((ch_n - Z_k)I_{\{\Delta_k^N \geq 2\}} - \mu Y_k I_{\{\Delta_k^N \geq 2\}} \neq 0 \right) \]

\[ \leq P\left( \bigcup_{k=1}^{n} \{\Delta_k^N \geq 2\} \right) \]

\[ \leq O(nh_n^2). \tag{A.4} \]

Therefore, we only need to compute the limit in distribution of the third term of (A.1).

By Mancini [19], we know \( \text{Plim}_{n \rightarrow \infty} I_{\{\Delta_k^N = 1\}} = \text{Plim}_{n \rightarrow \infty} I_{\{\Delta_k^N = 1\}} \), then

\[ d \lim_{n \rightarrow \infty} \sqrt{nh_n}\left( \frac{1}{cnh_n} \sum_{k=1}^{n} (ch_n - Z_k)I_{\{\Delta_k^N = 1\}} - \frac{\lambda \mu}{c} \right) \]

\[ = d \lim_{n \rightarrow \infty} \sqrt{nh_n}\left( \frac{1}{cnh_n} \sum_{k=1}^{n} (ch_n - Z_k)I_{\{\Delta_k^N = 1\}} - \frac{\lambda \mu}{c} \right). \tag{A.5} \]

Because the random variables \( \gamma_k \), \( N \), and \( W \) are independent to each other and \( \gamma_k \) are i.i.d, we have (A.5) that tends to \( N(0, (\lambda (\mu^2 + \sigma^2) /c^2)) \) in distribution as \( n \rightarrow \infty \). Thus, we can obtain (19). By (19) and Slutsky’s Theorem, it is easy to obtain (18).

Next, by (7) and (16), we have

\[ \sqrt{nh_n}\left( \mathcal{L}_{\Phi}(s) - \mathcal{L}_{\Phi}(s) \right) \]

\[ = \sqrt{nh_n}\left( \frac{\tilde{\rho}}{(1/c)(\psi^*) (s + \theta)} - \frac{\rho}{(1/c)(\psi^*) (s + \theta)} \right) \]

\[ = \sqrt{nh_n}\left( \frac{\tilde{\rho}}{(1/c)(\psi^*) (s + \theta)} - \frac{\rho}{(1/c)(\psi^*) (s + \theta)} + \psi^* (s + \theta) (\tilde{\rho} - \rho) \right). \tag{A.6} \]

By Slutsky’s Theorem, (11), (9), and (A.6), we have
Lemma 1 (see Theorem 3.2 in [24]).

Mathematical Problems in Engineering 7
Suppose that for a function

\[ f \in L^2(0, \infty) \]

the derivative \( f' \), \( \int_0^\infty [t(t^{1/2} f(t))]' t^{-1}dt < \infty \), then

\[
\sqrt{n h_n} (\mathcal{D}_{\phi_n}(s) - \mathcal{D}_{\phi}(s)) \approx \sqrt{n h_n} \frac{\rho \psi_Y(s + \theta) - \psi_Y(s + \theta) + \psi_Y(s + \theta)(\rho - \rho)}{(1/c) \psi_Y(s + \theta)^2} + o_p(1)
\]

\[
\approx \sqrt{n h_n} \frac{\psi_Y(s + \theta) \left( \sum_{k=1}^n (c h_n - Z_k) I_{\mathcal{D}_{\phi}(s)} c h_n \right) - \rho}{(1/c) \psi_Y(s + \theta)^2} + o_p(1)
\]

\[
= - \sqrt{n h_n} \frac{\rho \left( (1/n) \sum_{k=1}^n e^{(s+\theta) Z_k} - 1/n h_n \right) - \psi_Y(s + \theta) + o_p(1)}{(1/c) \psi_Y(s + \theta)^2}
\]

\[
\approx \sqrt{n h_n} \frac{n \psi_Y(s + \theta) \left( (c h_n - Z_k) I_{\mathcal{D}_{\phi}(s)} c h_n \right) - \rho \left( e^{(s+\theta) Z_k} - 1/n h_n \right)}{(1/c) \psi_Y(s + \theta)^2} + o_p(1)
\]

(A.7)

\[
\approx \frac{1}{\sqrt{n h_n}} \sum_{k=1}^n \frac{n \psi_Y(s + \theta) \left( (c h_n - Z_k) I_{\mathcal{D}_{\phi}(s)} c h_n \right) - \rho c \left[ e^{(s+\theta) Z_k} - 1 \right]}{(\psi_Y(s + \theta))^2}
\]

+ o_p(1).

By \( \lim_{n \to \infty} I_{\mathcal{D}_{\phi}(s)} = \lim_{n \to \infty} I_{\mathcal{D}_{\phi}(s)}^{\Delta_n^{N=1}} \),

\[
d \lim_{n \to \infty} \frac{1}{\sqrt{n h_n}} \sum_{k=1}^n \frac{n \psi_Y(s + \theta) \left( (c h_n - Z_k) I_{\mathcal{D}_{\phi}(s)} c h_n \right) - \rho c \left[ e^{(s+\theta) Z_k} - 1 \right]}{(\psi_Y(s + \theta))^2} = 0
\]

(A.8)

The proof of Theorem 2

Proof. Using (17),

\[
\|\Phi_m - \Phi_n\|^2 \leq 2e^{20h} \left( \|\Phi_m e^{-\theta h} - \Phi_n\|^2 + \|\mathcal{D}_{\phi} - \mathcal{D}_{\phi}\|^2 \right)
\]

(A.11)

Lemma 1. Suppose that for a function \( f \in L^2(0, \infty) \) with the derivative \( f' \), \( \int_0^\infty [t(t^{1/2} f(t))]' t^{-1}dt < \infty \), then

\[
\int_0^\infty \left[ x(\sqrt{x} \Phi(x))' \right]^2 (1/x) dx \leq \int_0^\infty \Phi_0(x) dx + \int_0^\infty x^2 g_0(x) dx
\]

\[
\leq \|\Phi_0\|^2 + \int_0^\infty x^2 [g(x)e^{-\theta x} - \Phi(x)e^{-\theta x}]^2 dx
\]

\[
\leq \|\Phi_0\|^2 + \int_0^\infty x^2 g_0(x)e^{-20h} dx + \int_0^\infty x^2 \Phi_0(x)e^{-20h} dx
\]

\[
\leq \|\Phi_0\|^2 + \int_0^\infty x^2 e^{-20h} (M^2 + 1) dx < \infty.
\]

(A.12)
By Lemma 1,
\[
\left\| \mathcal{L}_m^{-1} \mathcal{L}_\Phi - \Phi \right\|^2 = O\left( \frac{1}{\log m} \right), \quad m \to \infty. \quad (A.13)
\]

Using the proof of Propositions 2.3 and 2.4 in You and Cai [17], the right-hand side in (A.14) is bounded by
\[
\frac{2}{(1 - \rho)^2} I_1 + \frac{2(\bar{\rho} - \rho)^2}{(1 - \rho)^2} I_2, \quad (A.15)
\]
where
\[
I_1 = \int_0^\infty \frac{1}{c^2} \left( \hat{\Psi}_Y (s + \theta) - \Psi_Y (s + \theta) \right)^2 ds, \quad (A.16)
\]
\[I_2 = \int_0^\infty \frac{1}{(s + \theta)^2} ds < \infty.
\]
By Theorem 1, it follows that
\[
I_1 = O_p \left( \frac{1}{nh_n} \right), \quad (A.17)
\]
\[
\frac{2}{(1 - \rho)^2} = O_p (1), \quad (A.18)
\]
By (7), (12), (15), and (16), we have
\[
\frac{2(\bar{\rho} - \rho)^2}{(1 - \rho)^2} = O_p \left( \frac{1}{nh_n} \right), \quad (A.19)
\]
Combining (A.15) and (A.17)–(A.19) yields
\[
\left\| \mathcal{L}_m^{-1} \mathcal{L}_\Phi - \Phi \right\|^2 = O_p \left( \frac{1}{nh_n} \right), \quad n \to \infty. \quad (A.20)
\]
By \( L_{m}^{-1} \leq \sqrt{m} \) in Chauveau et al. [24], (A.13), and (A.20), we have
\[
\left\| \Phi_{m(n)} - \Phi \right\|^2 = O_p \left( \frac{m^2}{nh_n} \right) + O_p \left( \frac{1}{\log m} \right). \quad (A.21)
\]

With an optimal \( m = \sqrt{nh_n/\log nh_n} \), balancing the right-hand two terms in (A.21), the order becomes \( O_p \left( (\log nh_n)^{-1} \right) \).

**Proof of Theorem 3**

Since \( J = J_1 + J_2 \) and (11),
\[
\bar{\rho} - \rho = \frac{\sum_{k=1}^n \left( c h_k - Z_k \right) I_{2m}^{\mu_k} - \mu_k}{cnh_n}
\]
\[
\leq \frac{\sum_{k=1}^n \left( \Delta_k^{\mu_1} - \sigma \left( W_{k}^{\mu_1} - W_{k-1}^{\mu_1} \right) \right) I \left\{ \left| \Delta_k^{\mu_1} \right| - \sigma \left| W_{k}^{\mu_1} - W_{k-1}^{\mu_1} \right| \right\}^{(1/2)h_k} - E [ J_{11} ]}{cnh_n}
\]
\[
+ \frac{\sum_{k=1}^n \Delta_k^{\mu_1} I_{2m}^{\mu_k} - E [ J_{21} ]}{cnh_n}
\]
\[
+ \frac{\sum_{k=1}^n \frac{\Delta_k^{\mu_1} I_{2m}^{\mu_k} - E [ J_{21} ]}{cnh_n}}{cnh_n}
\]
Let us consider the second term of (A.22),
By the Paul Lévy law for the modulus of continuity of Brownian motion's path (Vondraček and Shreve [31], p.114, Theorem 9.25) implies that

\[
\lim_{h_n \to 0, k \in \{1, \ldots, n\}} \sup_{0 < k < h_n} \frac{\left| W_{t_k} - W_{t_{k-1}} \right|}{\sqrt{h_n \ln (1/h_n)}} \leq 1, \text{ a.s.} \quad (A.24)
\]

We have

\[
\frac{\sum_{k=1}^{n} \left| \sigma \left(W_{t_{k-1}} - W_{t_{k}}} \right) \right| I_{\left[ \left| \Delta^n_{j} \right| > \left( h^b_n / 2 \right) \right]} }{cnh_n} \leq \frac{h_n \ln \left( \frac{1}{h_n} \right) \sum_{k=1}^{n} I_{\left[ \left| \Delta^n_{j} \right| > \left( h^b_n / 2 \right) \right]} }{cnh_n} \quad \text{as } n \to \infty \text{ and } b \in (0, (1/4)).
\]

Moreover,

\[
P \left( \frac{\sum_{k=1}^{n} \left| \Delta^n_{j} \right| I_{\left[ \left| \Delta^n_{j} \right| > \left( h^b_n / 2 \right) \right]} }{cnh_n} \neq 0 \right) \leq P \left( \frac{\sum_{k=1}^{n} \left| \sum_{j=1}^{n} \Delta^n_{j} \right| I_{\left[ \left| \Delta^n_{j} \right| > \left( h^b_n / 2 \right) \right]} }{cnh_n} \neq 0 \right)
\]

\[
\leq nP \left( \Delta \neq 0 \right) \frac{\sum_{k=1}^{n} \left| \Delta^n_{j} \right| \left( \Delta^n_{j} \right)^2 }{h^b_n} = nO \left( \frac{\sigma^2(1)h_n^{1/4}}{h_n^{2b/4}} \right) \to 0,
\]

since for \( \forall \beta > 0, nh^{1+\beta} \to 0 \).

Now, let us consider the last term of the right-hand side of (A.22):
\[
\sum_{k=1}^{n} \Delta_{k}^{n} J_{I} e_{\theta_{n}} = \sum_{k=1}^{n} \Delta_{k}^{n} J_{I} \left( \left\{ \left| x_{k} - x_{k-1} \right| \in [k,2k] \right\} \right) \leq \sum_{k=1}^{n} \Delta_{k}^{n} J_{I} \left( \left\{ \left| x_{k} - x_{k-1} \right| \leq 2 \theta_{n} \right\} \right) + \sum_{k=1}^{n} \Delta_{k}^{n} J_{I} \left( \left\{ \left| x_{k} - x_{k-1} \right| > 2 \theta_{n} \right\} \right) \leq \sum_{k=1}^{n} \Delta_{k}^{n} J_{I} \left( \left\{ \left| x_{k} - x_{k-1} \right| \leq 2 \theta_{n} \right\} \right) + \sum_{k=1}^{n} \Delta_{k}^{n} J_{I} \left( \left\{ \left| x_{k} - x_{k-1} \right| > 2 \theta_{n} \right\} \right) \leq \sum_{k=1}^{n} \Delta_{k}^{n} J_{I} \left( \left\{ \left| x_{k} - x_{k-1} \right| \leq 2 \theta_{n} \right\} \right) \]
\[ a_m = \left\| \mathcal{L}_m \varphi_\theta - \varphi_\theta \right\|^2 = O \left( \frac{1}{\log m} \right), \quad m \to \infty, \]
\[ (A.36) \]

\[ \left\| \mathcal{L}_\theta - \mathcal{L}_\theta \right\|^2 
  = \int_0^\infty \left( \frac{(\rho - 1) ((1/c)\psi_Y(s+\theta) - (1/c)\psi_Y(s+\theta))}{(1/c)\psi_Y(s+\theta) (1/c)\psi_Y(s+\theta)} \right)^2 ds 
  + \frac{(\rho - \rho)}{(1/c)\psi_Y(s+\theta)} ds 
  \leq \frac{2}{(1 - \rho)^2} I_1 + \frac{2(\rho - \rho)}{(1 - \rho)^2} I_2, \]
\[ (A.37) \]

where
\[ I_1 = \int_0^\infty \frac{1}{c^2} \frac{(\psi_Y(s+\theta) - \psi_Y(s+\theta))^2}{(s+\theta)^2} ds, \]
\[ I_2 = \int_0^\infty \frac{1}{(s+\theta)^2} ds < \infty. \]
\[ (A.38) \]

By Theorem 3 and continuous mapping theorem, it follows that
\[ \left\| \mathcal{L}_\theta - \mathcal{L}_\theta \right\|^2 = o_P(1), \quad n \to \infty. \]
\[ (A.39) \]

Combining \(L_m \leq \sqrt{m} \) in Chauveau et al. [24], (A.36), and (A.39), we have
\[ \left\| \varphi_m - \varphi \right\|^2 \leq m^2 o_P(1) + a_m, \]
\[ (A.40) \]
as \( n \to \infty. \]

\[ \square \]
