ABSTRACT: We investigate superconformal surface defects in four-dimensional $\mathcal{N} = 2$ superconformal theories. Each such defect gives rise to a module of the associated chiral algebra and the surface defect Schur index is the character of this module. Various natural chiral algebra operations such as Drinfeld-Sokolov reduction and spectral flow can be interpreted as constructions involving four-dimensional surface defects. We compute the index of these defects in the free hypermultiplet theory and Argyres-Douglas theories, using both infrared techniques involving BPS states, as well as renormalization group flows onto Higgs branches. In each case we find perfect agreement with the predicted characters.

1 Introduction

In this paper we discuss four-dimensional $\mathcal{N} = 2$ superconformal field theories coupled to conformally invariant two-dimensional $(2,2)$ surface defects $S$. We investigate the defect Schur index

$$I_S(q) = \sum_{\mathcal{O}_{2d-4d}} e^{2\pi i R q^{R-M_\perp}},$$

(1.1)

where in the above $R$ denotes the SU(2) $R$-charge and $M_\perp$ rotations transverse to the defect. This index counts operators in the presence of the defect, which are simultaneously chiral with respect to both the left and right $2d$ supersymmetry algebras.

Our main results are computations of these defect indices for the free hypermultiplet theory and strongly-coupled Argyres-Douglas CFTs, using both renormalization group flows along Higgs branches, as well as recent Coulomb branch formulas that express the defect indices in terms of $2d$ BPS particles. We also explain how our results agree with the general relationship between surface defect Schur indices and chiral algebra characters.

1.1 Surface defects and chiral algebras

The Schur index $I(q)$ introduced in [1–3] is a specialization of the superconformal index which counts quarter-BPS local operators in superconformal field theories. This specialization is particularly interesting because of its remarkable connection to disparate areas of mathematical physics, including topological field theory [2, 4], vertex operator algebras [5], and BPS wall-crossing phenomena [6, 7].

The Schur index $I(q)$ may be enriched by considering the superconformal field theory in the presence of superconformal defects, such as lines, surfaces, or boundary conditions. These defects are useful probes of dualities and allow us to explore the possible phases of gauge theories. The defect generalization of the Schur index then counts supersymmetric local operators bound to the defect. Our focus in this work is on surface defects $S$ that preserve $(2,2)$ superconformal symmetry. A review of many of the properties of these defects is given in [8].

A powerful organizing principle for general Schur indices was introduced in [5] and further developed in [9–18]. In those works, it was deduced on general grounds that for a conformal field theory, the local operators contributing to $I(q)$ form a two-dimensional non-unitary chiral algebra. In particular it follows from this analysis that the Schur index is the vacuum character of this chiral algebra.

The chiral algebra perspective remains useful in the presence of a surface defect $S$. As we argue in section 3, the defect local operators contributing to the Schur index form a module over the original chiral algebra. Therefore the defect Schur index $I_S(q)$ is the character of some non-trivial module of the chiral algebra. These conclusions have also been obtained in [19]. As we further discuss, many natural operations at the level of chiral algebras may be interpreted as constructions on four-dimensional field theories in the presence of surface defects.

One simple observation concerns the four-dimensional meaning of spectral flow of chiral algebra modules. Given a surface defect $S$ in a theory with a global symmetry U(1), we
may “twist” this defect into a one-parameter family $S^{(\alpha)}$. The modules of $S$ and $S^{(\alpha)}$ are then related by spectral flow by $\alpha$ units.

Another useful point concerns the behavior of the chiral algebra along Higgs branch renormalization group flows. Let $\mathcal{T}_{UV}$ and $\mathcal{T}_{IR}$ be two theories related by a flow along the Higgs branch of $\mathcal{T}_{UV}$ parameterized by a nilpotent vev of a flavor moment map operator. Then, as discussed in [9], the chiral algebras of $\mathcal{T}_{UV}$ and $\mathcal{T}_{IR}$ appear to be related by quantum Drinfeld-Sokolov reduction. This agrees with the statement that the characters, i.e. Schur indices, are related by a simple residue prescription [20]. Expanding on these results, one may naturally consider a class of vortex surface defects. We claim that the chiral algebra modules associated to these defects are obtained by performing Drinfeld-Sokolov reduction on the spectral flow of the vacuum module of $\mathcal{T}_{UV}$. In particular this agrees with the simple residue prescription for evaluating the defect Schur index [20]. We review this method in section 2.3.

Together these techniques allow us to obtain a precise description of the chiral algebra modules associated to many surface defects.

1.2 The hypermultiplet and Argyres-Douglas theories

After reviewing the basic properties of the surface defect Schur index and its interpretation via chiral algebras we proceed to examples.

All the theories we consider in our calculations are class $S$ theories of type $A_1$. The class $S$ definition equips these theories with an infinite family of surface defects $S_r$, labelled by a non-zero weight of SU(2), i.e. a positive integer [21–23]. All these defects also admit a uniform four-dimensional description as vortex defects [20]. The simplest such defect, sometimes called the canonical surface defect $S_1$ (or simply $S$) also has a rather well-understood spectrum of 2$d$-4$d$ BPS particles. This makes many calculations possible.

We first turn to a detailed investigation of the surface defect $S$ in the free hypermultiplet theory [23]. Despite the fact that the bulk theory is free, the defect $S$ is in fact strongly-coupled and poorly understood.

We use two different techniques to evaluate the index $I_S(q)$. First, we use the infrared formulas of [24] (reviewed in section 2.2) to find a formula for the defect Schur index using the 2$d$-4$d$ BPS spectrum. We compare our results with the Higgsing procedure [20]. Both methods give the same answer, with some important subtleties.\footnote{The answer has to be treated with care due to an infinite tower of operators contributing an overall factor of $\sum_{n=-\infty}^{\infty} z^n$ to the Schur index, where $z$ is a flavor fugacity. Such infinite sums tend to give zero when the indices are manipulated as actual rational functions of the fugacities rather than generating functions.} In appendix B we clarify these subtleties by computing the full three-variable superconformal index for the vortex defects of the hypermultiplet using the Higgsing procedure.

We further explore the interpretation of defect local operators as a module for the bulk chiral algebra. The hypermultiplet is associated to the $\beta\gamma$ chiral algebra [5] and we describe the corresponding module. We also briefly discuss higher $S_r$ defects.

We then move on in section 5 to consider applications to surface defects in Argyres-Douglas theories [25, 26]. These theories are an ideal set of examples to illustrate the power of the infrared formula of [24] as well as the unifying chiral algebra interpretation...
of the resulting indices. Indeed, the BPS spectra of Argyres-Douglas theories have been computed both with and without defects [27–34]. Moreover the associated chiral algebras have been identified in [5, 7, 18, 35–38] and further studied in [39–42]. Thus, although these theories have no simple Lagrangian formulation we may still apply our technology. We may also compare our results to the recently proposed general superconformal indices of Argyres-Douglas theories [39, 43–46]

We carry out explicit calculations for the canonical surface defects $S$ of $A_n$ type Argyres-Douglas theories which have natural constructions in M-theory, both using BPS spectra and Higgsing. We find that for $A_{2n}$ our results reproduce the character of the primary $\Phi_{1,2}$ in the $(2, 2n + 3)$ Virasoro minimal model

$$I_S(q) = \chi^{(2, 2n+3)}_{(1,2)}(q),$$

for the canonical surface defect and characters of other primary fields $\Phi_{1,k+1}$ for general canonical surface defects $S_k$ of not too large $k$.

Meanwhile for $A_{2n+1}$ our calculations reproduce the non-vacuum characters of the $W_{n+1}^{(2)}$ chiral algebra (a certain Drinfeld-Sokolov reduction of the SU($n + 1$) Kac-Moody algebra).

2 Computational methods for 2d-4d Schur indices

In this section we briefly review 2d-4d Schur indices, and various approaches that may be used to calculate them.

A (2, 2) conformal surface defect $S$ in a 4d $\mathcal{N} = 2$ conformal field theory preserves the following subalgebra of the bulk superconformal algebra SU(2, 2):

$$\text{SU}(1, 1) \times \text{SU}(1, 1) \times U(1)_C \subset \text{SU}(2, 2).$$

The factors $\text{SU}(1, 1) \times \text{SU}(1, 1)$ are the global charges of the (2, 2) superconformal algebra, while $U(1)_C$ is the commutant of the embedding and is therefore a universal flavor symmetry enjoyed by every conformal surface defect. In terms of bulk symmetries,

$$C = R - M_\perp,$$

where $R$ is the Cartan of SU(2) and $M_\perp$ generates rotations transverse to the defect.

The defect Schur index is a generalization of (a limit of) the elliptic genus of (2, 2) theories to include the coupling to the 4d bulk. It takes the form

$$I_S(q) = \sum_{O_{2d-4d}} \left[ e^{2\pi i R} q^{R-M_\perp} \right].$$

Here the sum is over operators in the presence of the defect, and the variable $q$ grades these operators by their flavor charge $C$. As compared to the most general index, the Schur limit enjoys enhanced supersymmetry. From the (2, 2) point of view, it receives contributions only from operators in the (chiral, chiral) sector.

These theories are also known as the $(A_1, A_n)$ Argyres-Douglas theories in the terminology of [30].

Here we have chosen a slightly unusual 4d fermion number $F_{4d} = 2R$, which is more convenient in our calculations.
2.1 Localization techniques

In the special case when both the 2\textit{d} theory on the surface defect \(\mathcal{S}\) and the 4\textit{d} bulk theory have Lagrangian descriptions, the 2\textit{d}-4\textit{d} index can be computed straightforwardly. Since the index is invariant under marginal deformation, we can choose to work at the zero coupling point and enumerate the operators there. The final answer for the 2\textit{d}-4\textit{d} index takes the form of a finite-dimensional integral and has been explored for various 2\textit{d}-4\textit{d} systems in [24, 47, 48].

First, we consider the 4\textit{d} Schur index without defects. Suppose the theory is defined by gauge group \(G\) and hypermultiplets in representation \(R\) of \(G\), and \(F\) of the flavor symmetry. The Schur index refined by flavor fugacities \(x\) is given by

\[
\mathcal{I}(q; x) = \int [du] \text{P.E.} \left[ f^V(q)\chi_G(u) + f^{1/2}H(q)\chi_R(u)\chi_F(x) \right],
\]

where \([du]\) is the Haar measure on the maximal torus of \(G\) and \(\chi_\alpha\) are characters of the gauge and the flavor group. Here \(f^V(q)\) and \(f^{1/2}H(q)\) are the single letter indices of a free vector multiplet and a half-hypermultiplet,

\[
f^V(q) = -\frac{2q}{1-q}, \quad f^{1/2}H(q) = -\frac{q^{1/2}}{1-q}.
\]

Finally, P.E. is the plethystic exponential,

\[
\text{P.E.}[f(q; u, x)] = \exp \left[ \sum_{n=1}^{\infty} \frac{1}{n} f(q^n; u^n; x^n) \right].
\]

We now consider 2\textit{d}-4\textit{d} systems constructed from gauging a 2\textit{d} flavor symmetry on the defect \(\mathcal{S}\) by 4\textit{d} gauge fields. Using the localization formula developed in [48-50], we first compute a limit of the NS-NS sector elliptic genus

\[
\mathcal{G}_{(c, c)}(u) = \text{Tr}_{\text{NSNS}} \left[ (-1)^{F_{2d}} q^{L_0-J_0/2} \bar{q}^{\bar{L}_0-\bar{J}_0/2} u^K \right],
\]

where \(u\) is a flavor fugacity for the 2\textit{d} flavor group \(K\). This is the limit of the genus that counts only \((c, c)\) operators, and hence depends only on flavor variables.

The 2\textit{d}-4\textit{d} Schur index is then a simple generalization of (2.4) by inserting the contribution from the defect,

\[
\mathcal{I}_\mathcal{S}(q, x) = \int [du] \text{P.E.} \left[ f^V(q)\chi_G(u) + f^{1/2}H(q)\chi_R(u)\chi_F(x) \right] \mathcal{G}_{(c, c)}(u).
\]

For example applications of this formula see e.g. [24].

2.2 The infrared formula

In this section we review the infrared formula of [24] for computing defect Schur indices in terms of Coulomb branch data. This formula intertwines the Cecotti-Vafa formula [51, 52] expressing limits of the elliptic genus in terms of 2\textit{d} BPS soliton degeneracies with recent formulas expressing the 4\textit{d} Schur index (and generalizations) in terms of 4\textit{d} BPS particles [6, 7, 40, 41].
On the Coulomb branch, the bulk dynamics is that of an abelian gauge theory with
gauge group $U(1)^r$ \cite{53, 54} ($r$ is typically called the rank of the theory), while the defect
theory is typically gapped with $N$ vacua. There are various BPS objects that can appear
in this coupled system \cite{23}. These may carry electromagnetic charges $\gamma$ valued in a lattice
$\Gamma$ and as well may carry spin (denoted $n$ below). We count them with appropriate indices.

- **4d BPS particles** counted by indices $\Omega(\gamma, n)$.
- **2d BPS particles** counted by indices $\omega_i(\gamma, n)$ where $i$ indicates a 2d vacuum.
- **2d BPS solitons** counted by indices $\mu_{ij}(\gamma, n)$ where $i \neq j$ indicates a pair of 2d vacua.

From these indices we build a wall-crossing operator $S^{2d-4d}_{\vartheta, \vartheta + \pi}(q)$ which is an $N \times N$
matrix, whose entries are power series in a quantum torus algebra of variables $X_{\gamma}$ obeying

\[ X_{\gamma}X_{\gamma'} = q^{\frac{1}{2}\langle \gamma, \gamma' \rangle}X_{\gamma+\gamma'}, \tag{2.9} \]

where $\langle \gamma, \gamma' \rangle$ is the Dirac pairing. The wall-crossing operator encodes the part of the
spectrum whose central charge phases lie in the half-space $\text{arg}(Z) \in [\vartheta, \vartheta + \pi)$. It takes the
form of a phase ordered product

\[ S^{2d-4d}_{\vartheta, \vartheta + \pi}(q) =: \prod_{i,j,\vartheta, \vartheta + \pi} S_{ij; \gamma} K^{2d}_{ij; \vartheta} K^{4d}_{\gamma} : , \tag{2.10} \]

where the normal ordering means that each factor is ordered according to increasing central
charge phase.

The individual matrices in (2.10) depend on the refined indices introduced above. Let
$\delta^i_j$ indicate the $N \times N$ identity matrix, and $e^i_j$ an $N \times N$ matrix whose only non-vanishing
entry is in the $i$-th row and $j$-th column. Then, the factors are defined as follows:

- The 4d particles with gauge charge $\gamma$ contribute factors of

\[ K^{4d}_{\gamma}(q; \Omega_j(\gamma)) = \prod_{n\in\mathbb{Z}} E_q((-1)^nq^{n/2}X_{\gamma})^{-\Omega_n(\gamma)} \delta^j_i . \tag{2.11} \]

Here $E_q(z)$ is the quantum dilogarithm defined as

\[ E_q(z) = (-q^{\frac{1}{2}}z; q)^{-1}_\infty = \prod_{i=0}^{\infty} (1 + q^{i+\frac{1}{2}}z)^{-1} = \sum_{n=0}^{\infty} \frac{(-q^{\frac{1}{2}}z)^n}{(q)_n} , \tag{2.12} \]

and as usual $(q)_n = \prod_{j=1}^{n}(1 - q^j)$.

- The 2d particles in the $i$-th vacuum with gauge charge $\gamma$ contribute factors of

\[ K^{2d}(q; X_\gamma; \omega_i(\gamma, n)) \equiv \sum_i \prod_{n\in\mathbb{Z}} (1 - (-1)^nq^{\frac{3}{2}}X_\gamma)^{-\omega_i(\gamma, n)} e^i_j . \tag{2.13} \]

- The 2d solitons with topological charge $ij$ and gauge charge $\gamma$ contribute factors of

\[ S_{ij}(q; X_\gamma, \mu_{ij}(\gamma, k)) \equiv \delta^j_i - \sum_{k\in\mathbb{Z}} \mu_{ij}(\gamma, k)(-1)^kq^{\frac{3}{2}}X_\gamma e^j_k . \tag{2.14} \]
Note that the 2\textsuperscript{d} and 4\textsuperscript{d} particles carrying the same gauge charge \( \gamma \) appear at the same phase, hence we often group their contributions together by writing

\[
K_\gamma \equiv K^\text{4d}(q; X_\gamma; \Omega(\gamma, n)) K^\text{2d}(q; X_\gamma; \omega(\gamma, n)) .
\]  

(2.15)

With these preliminaries, we may now state the conjectured infrared formula of [24] for surface defect Schur indices. It reads

\[
\mathcal{I}_\mathfrak{g}(q) = (q)^{2r} \text{Tr} \left[ S^\text{2d-4d}_{\vartheta, \vartheta + \pi}(q) S^\text{2d-4d}_{\vartheta + \pi, \vartheta + 2\pi}(q) \right],
\]  

(2.16)

where on the right-hand side the trace operation is the ordinary trace on the \( N \times N \) matrix (arising from the defect vacua) as well as a trace operation on the quantum torus algebra. Specifically, we write the \( i\text{-}j \)-th entry of the wall-crossing operator as a series in torus algebra variables

\[
S^\text{2d-4d}_{ij, \vartheta, \vartheta + \pi}(q) = \sum_{\gamma} s_{ij}^\gamma X_\gamma.
\]  

(2.17)

Then,

\[
\text{Tr} \left[ S^\text{2d-4d}_{\vartheta, \vartheta + \pi}(q) S^\text{2d-4d}_{\vartheta + \pi, \vartheta + 2\pi}(q) \right] = \sum_{\gamma} s_{ij}^\gamma s_{ji}^{-\gamma}.
\]  

(2.18)

We can also obtain the dependence on flavor fugacities \( x \) in the index by identifying these variables with the commuting elements in the torus algebra and hence summing only over non-vanishing electromagnetic charges in (2.18).

### 2.3 Indices from Higgsing

Another useful way to construct surface defects and their indices is to use renormalization group flows along Higgs branches [20]. Suppose we are given a UV theory \( \mathcal{T}_{\text{UV}} \) with a flavor symmetry \( \text{U}(1)_f \). We consider a flow on the Higgs branch of \( \mathcal{T}_{\text{UV}} \) along a direction which spontaneously breaks both \( \text{SU}(2)_R \) and \( \text{U}(1)_f \) but preserves a diagonal combination of their Cartans. In the infrared we find a target theory of interest \( \mathcal{T}_{\text{IR}} \), together with free hypermultiplets that describe directions along the Higgs branch of \( \mathcal{T}_{\text{UV}} \) that do not belong to the Higgs branch of \( \mathcal{T}_{\text{IR}} \).

Note that such free hypermultiplets may or may not have non-standard quantum numbers under the \( \text{SU}(2)_R \) symmetry of the infrared theory. For instance the dilaton multiplet, which is universally present in such a flow, has a singlet parameterizing radial motion along the Higgs branch, as well as a triplet of goldstone bosons parameterizing angular directions. Such non-standard hypermultiplets are not included in the Higgs branch of \( \mathcal{T}_{\text{IR}} \).

On the other hand standard hypermultiplets may or may not be part of \( \mathcal{T}_{\text{IR}} \).

More generally instead of turning on a constant expectation value for the charged operator triggering the flow, we can instead choose a position-dependent profile for the operator. One interesting class of profiles are holomorphic configurations of the Higgs branch operators on a two-dimensional plane in \( \mathbb{R}^4 \) preserving 2\textsuperscript{d} \((2,2)\) supersymmetry. These flow to \((2,2)\) surface defects in the IR theory \( \mathcal{T}_{\text{IR}} \) known as \textit{vortex surface defects}. The name is justified by a modified definition involving dynamical vortices in a theory

\[\footnote{This is required so that \( \mathcal{T}_{\text{IR}} \) admits a superconformal stress tensor multiplet [55].}\]
where $U(1)_f$ is gauged. Later on, we will discuss a third perspective which constructs the same defects as a result of standard Higgs branch RG flow in the presence of a “monodromy defect” in the UV defined by a supersymmetric lump of background $U(1)_f$ flux.

As long as the IR $R$-symmetry matches the preserved combination of the UV $R$-symmetry and $U(1)_f$, the superconformal index of the IR theory, including potential vortex surface defects, can be computed from the superconformal index of the UV theory \cite{20}. To understand the essential idea, consider the analytic properties of the superconformal index of $\mathcal{T}_{UV}$. The UV Schur index has various poles in the $U(1)_f$ fugacity variable $x$. For generic values of the fugacities, there are no flat directions in $S^3 \times S^1$ background for the superconformal index and hence the index is finite. At the specific values of the flavor fugacity $x$ where the index develops a pole, a flat direction opens up in the corresponding $S^3 \times S^1$ background, allowing us to turn on a nonzero expectation value for the charged operator. Therefore the residues of the UV index at these poles are expected to be related to the indices of the IR theory $\mathcal{T}_{IR}$. More exactly, to obtain indices of $\mathcal{T}_{IR}$ from the residue, we must remove an overall prefactor accounting for the undesired hypermultiplets found in the flow.

In particular, for RG flows in class $S$ theories of type $A_{N-1}$, \cite{20} deduced that the $2d$-$4d$ Schur index for a vortex surface defect $S_r$ (with vortex number $r \in \mathbb{N}$) are captured by the poles in the $U(1)_f$ fugacity $x$ at $x = q^{\frac{r+1}{2}}$

$$I_{S_r}[\mathcal{T}_{IR}](q) = (-1)^a q^b N(q)^2 \operatorname{Res}_{x=q^{\frac{r+1}{2}}} \frac{1}{x} I[\mathcal{T}_{UV}](q). \quad (2.19)$$

Here the monomial $(-1)^a q^b$ is a theory dependent normalization factor (fixed by demanding that the index start from one), with $a, b$ being theory-dependent constants. The special case of the ordinary Schur index is $r = 0$ above which arises from the residue of the first pole at $x = q^{1/2}$.

Of course a given IR theory $\mathcal{T}_{IR}$ can typically be embedded into more than one UV theory, and the Higgsing procedure described above will generally give rise to different classes of vortex surface defects. In later sections we will apply the Higgsing procedure to both Lagrangian theories and strongly coupled Argyres-Douglas theories.

3 Chiral algebra interpretation of surface defects

The $(2,2)$ surface defects in four-dimensional $\mathcal{N} = 2$ conformal field theories admit a natural interpretation as modules of the associated chiral algebra. In this section we demonstrate this crucial fact, and discuss the $4d$-$2d$ dictionary relating operations on modules and constructions involving surface defects. For related work see \cite{19}.

Let us first review the situation in the absence of surface defects. For any four-dimensional $\mathcal{N} = 2$ superconformal field theory, a bijective correspondence between the Schur operators and the states in the vacuum module of an associated chiral algebra was established in \cite{5}. As a consequence, the Schur index equals the vacuum character of the chiral algebra. The OPEs between the $4d$ Schur operators reduce to those of the chiral algebra after passing to the cohomology of certain linear combinations of supercharges $Q_i, Q_i^\dagger (i = 1, 2)$.\newpage
3.1 Chiral algebra modules

In this section we show that a \((2, 2)\) conformal surface defect \textit{transverse} to the chiral algebra plane preserves the four supercharges \(Q_{\alpha}, Q^\dagger_{\dot{\alpha}}\) of the chiral algebra cohomology. The OPE between a \(4d\) bulk Schur operator with a \(2d-4d\) Schur operator can then be restricted to the \(Q\)-cohomology. This defines a chiral algebra action on the \(2d-4d\) Schur operators.

One immediate consequence is that the \(2d-4d\) Schur operators form a module of the chiral algebra. In particular, the Schur index for a \((2, 2)\) superconformal surface defect equals the character of a chiral algebra module.\(^5\) This provides a powerful organizing principle for superconformal surface defects in \(4d\) \(\mathcal{N} = 2\) conformal theories.

Let us verify the above statement on supercharges below. We will follow the convention of \([24]\) on the four-dimensional \(\mathcal{N} = 2\) superconformal algebra \(SU(2, 2)[2]\). Its maximal bosonic subgroup consists of the four-dimensional bosonic conformal group \(SO(2, 4)\) and the \(R\)-symmetry group \(SU(2)_R \times U(1)_r\). The nonvanishing anticommutators between the fermionic generators \(\{Q^A_{\alpha}, \tilde{Q}^{A\dot{\alpha}}, S^\alpha_A, S^{A\dot{\alpha}}\}\) are

\[
\begin{align*}
\{Q^A_{\alpha}, \tilde{Q}^{B\dot{\beta}}\} &= 2\delta_B^A \delta_\alpha^\beta \{P_\mu = \delta_B^A P_{\alpha \beta}\}, \\
\{S^{A\dot{\alpha}}, S^\beta_B\} &= 2\delta_B^A \delta^{\dot{\alpha} \beta} K_{\mu} = 2\delta_B^A \delta^{\dot{\alpha} \beta} \{P_\mu = \delta_B^A K_{\alpha \beta}\}, \\
\{Q^A_{\alpha}, S^\beta_B\} &= \frac{1}{2} \delta_B^A \delta^\beta_\alpha \Delta + \delta_B^A \delta_\alpha^\beta M_\beta - \delta_\alpha^\beta R^A_B, \\
\{S^{A\dot{\alpha}}, \tilde{Q}^{B\dot{\beta}}\} &= \frac{1}{2} \delta_B^A \delta^{\dot{\alpha} \beta} \Delta + \delta_B^A \delta^{\dot{\alpha} \beta} M_\beta + \delta_\beta^A R^{A\dot{\alpha}}_B,
\end{align*}
\]

where \(A, B = 1, 2\) are the doublet indices of \(SU(2)_R\), and \(\alpha, \beta = +, -, \dot{\alpha}, \dot{\beta} = \dot{+}, \dot{-}\) are the doublet indices of \(SU(2)_1 \times SU(2)_2 = SO(4)\) rotation. Here \(\Delta\) is the dilation generator and \(M_\alpha, M^\dot{\alpha}_\beta\) are the \(SO(4)\) rotation generators. \(R^A_B\) includes the generators of the \(SU(2)_R\) and the \(U(1)_r\).

A \((2, 2)\) conformal surface defect \(\mathcal{S}\) preserves an \(SU(1, 1|1) \times SU(1, 1|1) \times U(1)_C\) subalgebra of \(SU(2, 2)[2]\). Here \(SU(1, 1|1) \times SU(1, 1|1)\) is the global part of the \(2d\) \((2, 2)\) NS-NS superconformal algebra and \(U(1)_C\) is the commutant of this embedding. The nonzero (anti)commutators of \(SU(1, 1|1) \times SU(1, 1|1)\) are

\[
\begin{align*}
[L_0, G^+_r] &= -r G^+_r, & [\bar{L}_0, \bar{G}^+_r] &= -r \bar{G}^+_r, \\
[J_0, G^+_r] &= \pm G^+_r, & [\bar{J}_0, \bar{G}^+_r] &= \pm \bar{G}^+_r, \\
\{G^+_r, G^-_s\} &= L_{r+s} + \frac{r-s}{2} J_{r+s}, & \{\bar{G}^+_r, \bar{G}^-_s\} &= \bar{L}_{r+s} + \frac{r-s}{2} \bar{J}_{r+s}, & r, s = \pm 1/2.
\end{align*}
\]

The symmetry group \(SU(1, 1|1) \times SU(1, 1|1) \times U(1)_C\) of a surface defect lying on the \(12\)-plane can be embedded into the four-dimensional superconformal algebra by the following identification:

\[
G^+_{-\frac{1}{2}} = Q^2_+, \quad G^-_{-\frac{1}{2}} = \bar{Q}^-_2, \quad G^+_{-\frac{1}{2}} = Q^-_1, \quad G^-_{-\frac{1}{2}} = \bar{Q}^+_1.
\]

\(^5\)On the other hand, a non-conformal surface defect in a \(4d\) \(\mathcal{N} = 2\) superconformal field theory does not preserve the supercharges \(G^+_{1/2}, G^+_{1/2}\) that are used to construct \(\bar{Q}_1, \bar{Q}^1_1\) for the chiral algebra cohomology. Therefore, one cannot define the chiral algebra cohomology for this \(2d-4d\) system, and the \(2d-4d\) Schur index needs not be a character.
and similarly for their superconformal counterparts,

\[ G^{+}_{+\frac{1}{2}} = \tilde{S}^{\pm}_{-}, \quad G^{-}_{+\frac{1}{2}} = S^{+}_{2}, \quad G^{+}_{+\frac{1}{2}} = \tilde{S}^{1+}_{1}, \quad G^{-}_{+\frac{1}{2}} = S^{1-}_{1}. \]  

(3.4)

The identifications between the bosonic generators can be found, for example, in [24].

If we choose the chiral algebra plane to be the 34-plane (i.e. transverse to the surface defect plane), then the four supercharges \( Q_i \) and \( Q^{\dagger}_i \) (\( i = 1, 2 \)) that are used to construct the cohomology in [5] are

\[ Q_1 = Q^1_+ + \tilde{S}^{2-}_2, \quad Q_2 = S^{-}_1 - \tilde{Q}^{2-}_2, \]
\[ Q^{\dagger}_1 = S^{1-}_1 + S^{2+}_2, \quad Q^{\dagger}_2 = Q^{1-}_1 - \tilde{S}^{2-}_2. \]

(3.5)

Indeed as claimed above, the chiral algebra supercharges \( Q_i \) and \( Q^{\dagger}_i \) are preserved by the supercharges (3.3) and (3.4) of a transverse surface defect.

### 3.2 Spectral flows and monodromy defects

The notion of surface defect can be slightly generalized to allow for a flavor twist: a co-dimension two “twist” defect may live at the end of a topological domain wall implementing some flavor group rotation.

This construction is often important in discussing canonical surface defect in class \( S \) theories: both surface defects and certain protected bulk operators arise from co-dimension four defects in the six-dimensional (2,0) SCFTs. These defects have mild non-locality properties due to the fact that the 6d SCFTs are relative quantum field theories, i.e. live, strictly speaking, at the boundary of very simple seven-dimensional invertible topological field theories. As a consequence, some local operators may have a discrete monodromy around the canonical surface defects, which thus belong to a twisted sector. In particular, theories of type \( A_1 \) have a canonical \( \mathbb{Z}_2 \) flavor generator and \( S_{2n+1} \) belong to \( \mathbb{Z}_2 \) twisted sectors [23].

A priori there should be no relation between the surface defects which are available in distinct twisted sectors. In practice, though, we have found that at least as far as BPS or protected data is concerned, including the chiral algebra data, there is no obstruction in continuously deforming a given defect \( S \) into a family \( S^{(\alpha)} \) of defects in a sector twisted by \( \exp 2\pi i \alpha J_f \) for some U(1) flavor generator \( J_f \).

At the level of 2d-4d BPS spectra, this deformation simply shifts the angular momentum of BPS particles of charge \( q \) by \( \alpha q \). The twisted superpotential data of the surface defect can be left essentially unchanged.

Let \(|v\rangle_S\) be any state in the module of the surface defect \( S \). The protected part of the OPE of bulk operators at the defect, captured by the chiral algebra module relations,

\[ O^i(z)|v\rangle_S = \sum_{n \in \mathbb{Z}} \frac{1}{z^n} \left( O^i_{n-\Delta^i}\right)_{g,0} |v\rangle_S, \]

is deformed schematically to

\[ O^i(z)|v\rangle_S = \sum_{n \in \mathbb{Z}} \frac{1}{z^{n+\alpha q}} \left( O^i_{n-\Delta^i}\right)_{g,0} |v\rangle_S, \]

(3.7)

for current algebra primaries \( O^i \) with charges \( q_i \).
More precisely, we implement the deformation as a spectral flow deformation. Given a chiral algebra with a U(1) current subalgebra of level $k$, normalized so that the charges of operators in the algebra are integral, we can always bosonize the current as $J = -i \partial \phi$ and consider a free boson vertex operator

$$V_\alpha(z) = e^{i \alpha \phi}(z).$$

This defines a module which we can call “spectral flow of the vacuum module by $\alpha$ units”.

More generally, we can take the OPE of $e^{i \alpha \phi}(z)$ and any other module for the chiral algebra to produce a new, spectral flowed, module. Concretely, this can be described as the image of the original module under the action of the exponentiated zero mode $e^{i \alpha \phi_0}$. Alternatively, we can think about the spectral flow as an automorphism on the chiral algebra. It acts on the current, the Virasoro generators and other primaries $O^i$ of U(1) charge $q_i$ as

$$O^i_r \rightarrow O^i_{r+\alpha q^i},$$

$$J_n \rightarrow J'_n = J_n + a \alpha \delta_{n,0},$$

$$L_n \rightarrow L'_n = L_n + \alpha J_n + \frac{k}{2} \alpha^2 \delta_{n,0}.$$ (3.9)

By taking $\alpha$ to be integer we can deform any surface defect $S$ to an infinite discrete family of standard defects $S^{(\alpha)}$. If $S$ is the trivial defect we will call $S^{(\alpha)}$ monodromy defects.

We can give a physical justification for this deformation operation by observing that the components of a background bulk U(1) connection in the plane orthogonal to the surface defect enters the $(2,2)$ Lagrangian as the background value of a chiral multiplet, irrespectively of their dependence on the transverse directions. For example, the transverse kinetic terms of hypermultiplets arise from superpotential terms of the schematic form $X D_z Y$.

As a consequence, we can turn on such a background connection without breaking $(2,2)$ supersymmetry. If we take our connection to have a lump of $\alpha$ units of flux in the neighbourhood of the surface defect $S$ and flow to the IR, we will end up with a new surface defect $S^{(\alpha)}$ in a twisted sector shifted by $\alpha$. This manipulation affects protected quantities exactly as we desire for a monodromy defect.

### 3.3 Drinfeld-Sokolov reduction and Higgsing

As discussed in section 2.3, it is often the case one can find pairs of four-dimensional $\mathcal{N} = 2$ SCFTs, $\mathcal{T}_{\text{UV}}$ and $\mathcal{T}_{\text{IR}}$ which are related by an RG flow initiated by expectation values for Higgs branch operators. As the indices of $\mathcal{T}_{\text{UV}}$ and $\mathcal{T}_{\text{IR}}$ are related it is natural to expect that the chiral algebras are also related.

One challenge to this idea is that the construction of the chiral algebra relies heavily on superconformal symmetry. Since the Higgs branch flow spontaneously breaks this symmetry it is not completely obvious that there should be a standard prescription to compute the chiral algebra of $\mathcal{T}_{\text{IR}}$ from the chiral algebra of $\mathcal{T}_{\text{UV}}$. As proposed in [9], there is a very special situation where a candidate prescription exists and matches the index prescription: the situation where $\mathcal{T}_{\text{UV}}$ has a non-Abelian flavor symmetry $G$ and the RG
flow is triggered by the corresponding moment map operators $\mu_G$ getting an expectation value in some nilpotent direction, identified with the raising operator $t^+$ of some $\mathfrak{su}(2) \to \mathfrak{g}$ embedding, with the $\mathfrak{su}(2)$ Cartan generator $t^3$ playing the role of the spontaneously broken $U(1)_f$ flavor symmetry in section 2.3.

Then the corresponding chiral algebra operation is a quantum Drinfeld-Sokolov (qDS) reduction, which consists of three steps [56]:

- The stress tensor is shifted as $T \to T - t^3 \cdot \partial J$ so that the WZW current $t^+ \cdot J$ corresponding to the operator getting a vev has scaling dimension 0.

- Decompose the Lie algebra as $\mathfrak{g} = \oplus_n \mathfrak{n}_n$ according to the $t^3$ charge. Select a nilpotent subalgebra $\mathfrak{n} = \oplus_{n>1} \mathfrak{n}_n$. These are the currents which have acquired dimension less than or equal to zero after the shift of the stress tensor, corresponding to free hypermultiplets with non-standard $\mathfrak{su}(2)_R$ charge at the bottom of the RG flow. We may also include in $\mathfrak{n}$ some subspace of $\mathfrak{g}_1$, which is Lagrangian under the symplectic pairing $t^+ \cdot \{ \cdot , \cdot \}$, depending on how many free hypermultiplets with standard $\mathfrak{su}(2)_R$ charge do we want to keep in $\mathcal{T}_{IR}$.

- Add a collection of $bc$ ghosts is added, with $c$ valued in $\mathfrak{n}^*$. Take the cohomology by a standard BRST charge which sets $t^+ \cdot J = 1$ in cohomology and all other currents in $\mathfrak{n}$ to 0 in cohomology.

Notice that this prescription is usually employed on a $G$ current algebra, but it can also be employed on a general vertex operator algebra which has a $G$ current sub-algebra, as all operations and in particular the BRST charge only employ the Kac-Moody currents.

We can easily extend this discussion to the vortex surface defects of $\mathcal{T}_{IR}$ obtained by flows involving position dependent Higgs branch fields from $\mathcal{T}_{UV}$. Indeed, the qDS reduction can be implemented on modules for the chiral algebra as well leading to modules for the qDS-reduced chiral algebra. The modules associated to the vortex surface defects can be described simply in this language: they are the qDS reduction of a spectral flow image of the vacuum module of $\mathcal{T}_{UV}$. Note that this proposal matches the residue computation of the index for vortex surface defects discussed in section 2.3. It also allows an useful alternative point of view on vortex defects themselves as the infrared image of monodromy defects in $\mathcal{T}_{UV}$ associated to the $U(1)_f$ flavor symmetry employed in the RG flow.

The best known example of qDS reduction maps a Kac-Moody $\mathfrak{su}(2)_\kappa$ VOA to a Virasoro VOA with $c = 13 + 6(\kappa + 2) + 6(\kappa + 2)^{-1}$. For general values of $\kappa$ where the vacuum module of $\mathfrak{su}(2)_\kappa$ has no null vectors, this is a particularly simple reduction. The spin $j$ Weyl modules for $\mathfrak{su}(2)_\kappa$ map to degenerate modules of type $(1, 2j + 1)$, while the spectral flow images of the vacuum module of $\mathfrak{su}(2)_\kappa$ are mapped to degenerate modules of type $(n + 1, 1)$ and spectral flowed images of spin $j$ modules to degenerate modules of type $(n + 1, 2j + 1)$.

\footnote{The case where the charges of $t^3$ are odd has additional technical complications. See [57, 58] for details.}
For example, the qDS reduction acts on the vacuum character of SU(2)\(_{\kappa}\) by adding ghosts and then setting the SU(2) Cartan fugacity \(x_2 \to q^{1/2}\):

\[
\frac{1}{(q)_\infty (qx_2^2;q)_\infty (qx_2^{-2};q)_\infty} \rightarrow \frac{(x_2^2;q)_\infty (qx_2^{-2};q)_\infty}{(q)_\infty (qx_2^2;q)_\infty (qx_2^{-2};q)_\infty} \rightarrow \frac{1 - q}{(q)_\infty},
\]

(3.10)
gives the standard Virasoro vacuum module, with no other null vectors except \(L_{-1}\mid 0\).

If we introduce \(r\) units of spectral flow before the qDS reduction, the spectral flowed vacuum module maps to a degenerate Virasoro modules of type \((r+1,1)\) with a null vector at level \(r+1\): spectral flowing \(x_2 \to q^{r}x_2\), adding ghosts and then setting \(x_2 \to q^{1/2}\):

\[
\frac{q^{r^2}x^{r}_2 (x_2^2;q)_\infty (qx_2^{-2};q)_\infty (q^{1-r}x_2^{-2};q)_\infty}{(q)_\infty (qx_2^{r+1};q)_\infty (q^{1-r}x_2^{-2};q)_\infty} \rightarrow (-1)^r \frac{q^A_{(r+1,1)} (1 - q^{r+1})}{(q)_\infty}. \]

(3.11)

For special rational values of \(\kappa\) where the vacuum module of SU(2)\(_{\kappa}\) is smaller, we expect the correspondence to be somewhat modified. We will encounter precisely such examples of DS reduction when we employ the Higgsing procedure relating \(D_{n+3}\) and \(A_n\) Argyres-Douglas theories in section 5.

4 The free hypermultiplet

We begin our investigation of examples with the free hypermultiplet. The 4d BPS spectrum consists of a single hypermultiplet particle and its antiparticle. Hence the charge lattice \(\Gamma\) is one-dimensional and is generated by the flavor charge \(\gamma\) of the hypermultiplet. The Coulomb branch is a point and there is no wall-crossing phenomenon.

The story becomes more interesting when we introduce a canonical surface defect \(S\) into the free hypermultiplet theory. This surface defect is actually a rather mysterious, strongly interacting object. It may be defined through a class S construction \cite{23}. We realize the hypermultiplet by two M5-branes on the complex plane with an irregular singularity at infinity. The canonical defect is obtained placing an M2-brane at a point \(z\) on the plane. This M2-brane extends along two spacetime dimensions and hence gives rise to a surface defect.

There is no known explicit Lagrangian construction of this defect. It is expected that it is conformally invariant and breaks the SU(2) flavor symmetry to a U(1) subgroup. It should be most naturally viewed as a \(Z_2\)-twisted defect, around which the free hyper is anti-periodic. The point \(z \in \mathbb{C}\) at which the defect is placed corresponds to a twisted chiral relevant deformation of dimension 1/2, compatible with a twisted mass for the U(1). The defect has two massive vacua when either or both of these parameters are activated.

If \(z\) is sufficiently large, the mass of the solitons between the two vacua grows large and the surface defect is expect to “simplify” to a sum of two simpler defects with a single vacuum: two monodromy defects of twist \(\pm \frac{1}{2}\). Furthermore, multiple line defects exist which interpolate between the full surface defect and either of these simpler defects.

Our aim will be to learn about the spectrum of chiral operators on the defect using the infrared formula for the Schur index as well as Higgsing. To apply our formula (2.16) we require the full spectrum of this 2d-4d system. The spectrum depends on the defect
parameter $z$ and there is wall-crossing as $z$ is varied. Since our IR formula (2.16) for the 2d-4d Schur index is wall-crossing invariant, we can choose to work in a chamber with the simplest BPS particle spectrum.

As shown in [23], if we shift our conventions so that the surface defect is untwisted, there is a chamber where the BPS particle spectrum consists of a single 4d hypermultiplet particle with (flavor) charge $\gamma$, and a single 2d-4d soliton interpolating from vacuum one to vacuum two, as well as their antiparticles. The is also a 2d particle with $\omega_2(\gamma, 1) = -1$ and its antiparticle with $\omega_2(-\gamma, -1) = 1$. The phase order is such that $Z_{12}(z) < Z_{\gamma}(z)$. The corresponding factors are:

$$ S_{12;0} = \begin{pmatrix} 1 & -1 \\ 0 & 1 \end{pmatrix}, \quad S_{21;0} = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}, \quad (4.1) $$

and

$$ K_\gamma = \begin{pmatrix} E_q(X_\gamma) & 0 \\ 0 & E_q(q^{-1/2}X_\gamma) \end{pmatrix}, \quad K_{-\gamma} = \begin{pmatrix} E_q(X_{-\gamma}) & 0 \\ 0 & E_q(q^{-1/2}X_{-\gamma}) \end{pmatrix}, \quad (4.2) $$

where we incorporated the 2d contributions $1 + q^{1/2}X_\gamma$ and $(1 + q^{-1/2}X_{-\gamma})^{-1}$ into the 4d factors by a shift of their arguments.

If we go back to the conventions where the surface defect is a twist defect, we shift of the flavor fugacity $X_\gamma \rightarrow q^{-1/2}X_\gamma$. The wall-crossing factors for the canonical surface defect are then more symmetric

$$ K_\gamma = \begin{pmatrix} E_q(q^{-1/2}X_\gamma) & 0 \\ 0 & E_q(q^{1/2}X_\gamma) \end{pmatrix}, \quad K_{-\gamma} = \begin{pmatrix} E_q(q^{1/2}X_{-\gamma}) & 0 \\ 0 & E_q(q^{-1/2}X_{-\gamma}) \end{pmatrix}, \quad (4.3) $$

with $S_{12;0}$ and $S_{21;0}$ the same as above.

The physical interpretation is very simple at large $z$: the diagonal entries of the $K_\gamma$ factors collect the modes of the bulk hypermultiplet in the presence of the monodromy defects of twist $\pm \frac{1}{2}$, the $S$ factors contain the contributions of the solitons between these two vacua.

Our IR formula for the 2d-4d index gives

$$ I_2(q, x) = \text{Tr} [S_{12;0}K_\gamma S_{21;0}K_{-\gamma}] $$

$$ = \text{Tr} \left[ \begin{pmatrix} E_q(q^{-1/2}X_\gamma) & -E_q(q^{1/2}X_\gamma) \\ 0 & E_q(q^{1/2}X_\gamma) \end{pmatrix} \begin{pmatrix} E_q(q^{1/2}X_{-\gamma}) & 0 \\ 0 & E_q(q^{-1/2}X_{-\gamma}) \end{pmatrix} \right] $$

$$ = E_q(q^{-1/2}x)E_q(q^{1/2}x^{-1}) - E_q(q^{1/2}x)E_q(q^{1/2}x^{-1}) + E_q(q^{1/2}x)E_q(q^{-1/2}x^{-1}) $$

$$ = E_q(q^{1/2}x)E_q(q^{1/2}x^{-1}) \left[ \frac{1}{1 + x} - 1 + \frac{1}{1 + x^{-1}} \right] $$

$$ = 0, $$

where in the above $x = \text{Tr}[X_\gamma]$ is the fugacity for the U(1) flavor symmetry and is identified with the flavor variable $X_\gamma$ in the quantum torus algebra (2.9). In the final step above we have proceeded naively and cancelled the two summands against each other. Formally, that
would mean that the Schur index decorated by the canonical surface defect vanishes. This may mean one of two things: either the canonical defect has no protected chiral operators, including the identity, and hence likely breaks supersymmetry, or we were too hasty in our manipulations. We believe the second possibility actually occurs.

Indeed, our final manipulation was very suspicious: each of the two fractions in the penultimate step of our calculation really stands for an infinite geometric series, respectively in \( x \) and \( x^{-1} \), counting operators of non-zero positive or negative \( \mathbb{R} \) charge and \( R = M \). It seems too glib to resum these series and cancel them against each other. Instead, we should have probably written our answer as a formal Laurent series:

\[
\mathcal{Z}_\beta(q,x) = E_q(q^{\frac{1}{2}} x) E_q(q^{\frac{1}{2}} x^{-1}) \sum_{n \in \mathbb{Z}} x^n .
\] (4.5)

We will encounter a similar phenomenon when we compute the index in other ways: the answer naively vanishes, but only when we allow cancellations between rational terms which arise from power series with different regions of convergence.

4.1 \( \beta \gamma \)-system modules and the canonical surface defect

We will now explore the chiral algebra meaning of the index found in the previous section.\(^7\) As discussed in sections 3, the Schur operators on a conformal surface defect are a module over the chiral algebra associated to the bulk \( \mathcal{N} = 2 \) theory. In the case at hand the associated chiral algebra is simply the \( \beta \gamma \) system with weight \( h_\beta = h_\gamma = \frac{1}{2} \) [5], also known as symplectic bosons [59]. The OPE is,

\[
\beta(w)\gamma(0) \sim \frac{1}{w}, \quad \gamma(w)\beta(0) \sim -\frac{1}{w}.
\] (4.6)

Let \( \beta_n \) and \( \gamma_n \) be the modes of these currents,

\[
\beta(w) = \sum_{n \in \mathbb{Z}_+} \frac{\beta_n}{w^{n+\frac{3}{2}}} , \quad \gamma(w) = \sum_{n \in \mathbb{Z}_+} \frac{\gamma_n}{w^{n+\frac{1}{2}}} ,
\] (4.7)

where \( \nu = 0 \) (\( \nu = \frac{1}{2} \)) for a \( \mathbb{Z}_2 \)-twisted (untwisted) module. The algebra of the modes is

\[
[\beta_m,\gamma_n] = \delta_{m,-n} .
\] (4.8)

We can define a weight-1 current \( J(w) \) descended from the 4d U(1) flavor symmetry

\[
J(w) = - : \gamma \beta : (w) ,
\] (4.9)

under which \( \beta \) and \( \gamma \) carry +1 and \(-1\) charge, respectively. This is the current for the unbroken U(1) flavor symmetry in the presence of a \( \mathbb{Z}_2 \)-twisted surface defect.

The untwisted vacuum module is very simple: it is generated by a vacuum which is annihilated by all positive modes of \( \beta \) and \( \gamma \). The \( \mathbb{Z}_2 \)-twisted (aka Ramond) modules are more subtle, because of the presence of the zero modes \( \beta_0 \) and \( \gamma_0 \), which form an Heisenberg

\(^7\)We would like to thank Thomas Creutzig for an enlightening discussion on this point.
algebra. Simple highest weight twisted modules for the symplectic boson can be induced from any module for this Heisenberg algebra.

Spectral flow by $\pm \frac{1}{2}$ units of the vacuum module produce twisted modules generated by Heisenberg modules respectively of the form $\beta_0 |+\rangle$ with $\gamma_0 |+\rangle = 0$ and $\gamma_0 |{-}\rangle$ with $\beta_0 |{-}\rangle = 0$.

Physically, that means a defect OPE where one of the two complex fields in the hypermultiplet diverges as $w^{-\frac{1}{2}}$ and the other goes to zero as $w^{\frac{1}{2}}$ as a function of the transverse coordinate $w$. The corresponding characters are

$$I_s(q;x) = E_q(\frac{1}{2} x) E_q(\frac{1}{2} x^{-1}) x^{\frac{1}{2}} x^\pm c^n, \quad (4.10)$$

with a semi-infinite sum associated to either $\beta_0$ or $\gamma_0$ zero modes.

The direct sum of these two modules has an interesting deformation: we may set $0_{ji} + i = c_{ji}$ and $0_{ji} = c_{ji} + i$. This produces a "bilateral" module with a formal character

$$E_q(\frac{1}{2} x) E_q(\frac{1}{2} x^{-1}) x^{\frac{1}{2}} x^{-c} x^n. \quad (4.11)$$

Up to the overall power of $x$, which is normally neglected in the index, this agrees with $I_s(q,x)$.

Notice that the deformation shifts the current eigenvalue of $|\pm\rangle$ to $\pm \frac{1}{2} - c^2$. It is useful to denote $\lambda = \frac{1}{2} - c^2$ and the module as $R_\lambda$. The actual module depends on $\lambda$ up to integer shifts and degenerates when $\lambda$ is half-integral.

Physically, we expect that the surface defect supports an infinite series of chiral operators, which we are tempted to denote as $e^{n\Phi}$ with $\Phi$ being some chiral field valued on a cylinder, so that the two complex scalars in the hypermultiplet have a defect OPE

$$X(w) \sim ce^{\Phi} w^{-\frac{1}{2}} + O(w^{\frac{1}{2}}), \quad Y(w) \sim ce^{-\Phi} w^{-\frac{1}{2}} + O(w^{\frac{1}{2}}). \quad (4.12)$$

4.2 The full defect index from Higgsing

We can gain more information about this defect using the Higgsing procedure described in section 2.3. The free hypermultiplet can be obtained by moving onto the Higgs branch of the $D_4$ Argyres-Douglas theory whose Schur index is explicitly known [7, 36]. The canonical surface defect of the hypermultiplet is a vortex defect from this point of view and hence its Schur index can be obtained by taking an appropriate residue. We refer for further details to section 5 where we discuss Higgsing of general $D_{n+4}$ Argyres-Douglas theories.

The Schur index for the charge $r$ vortex defect obtained from Higgsing the $D_4$ theory is, up to an overall power of $q$, (see (5.48))

$$I_{s_r}(q,x) = \frac{1}{(q^2)^\infty} \sum_{k=0}^{\infty} [F_{4k-r+1} - F_{4k+r+3}] \quad (4.13)$$

where

$$F_s = \frac{q^{x^2} (1 - \eta^2 q^s)}{(1 - \eta x^{-1} q^{-\frac{1}{2}})(1 - \eta x q^{\frac{1}{2}})} \quad (4.14)$$
and we included a convergence factor $\eta$ to keep track unambiguously of how the denominators were expanded out in the original generating function: one should first expand in positive powers of $\eta$ and only then set $\eta \to 1$.

When $r = 0$ all denominator fugacities have positive powers of $q$ and the meaning of this expression is unambiguous. It expands out to match the standard free hypermultiplet index.

For $r = 1$ the sum telescopes to a simple answer involving a single term

\[
\frac{1}{(q^2)_{\infty}} F_0 = \frac{1}{(q^2)_{\infty}} \frac{1 - \eta^2}{(1 - \eta)(1 - \eta^{-1})} = \frac{1}{(q^2)_{\infty}} \sum_{n \in \mathbb{Z}} \eta^{|n|} x^n
\]  

This is the same answer as we obtained before, because the infinite sum behaves as a delta function:

\[
x^k \sum_{n \in \mathbb{Z}} x^n = \sum_{n \in \mathbb{Z}} x^n
\]  

and thus the infinite products $(q^2)_{\infty}$ match the expected $E_q(q^{\frac{1}{2}}x)E_q(q^{\frac{1}{2}}x^{-1})$.

For $r = 2$, the sum can be expressed in terms of the $r = 0$ answer:

\[
I_{S_2} = \frac{1}{(q^2)_{\infty}} (F_1 + F_{-1}) - I_{S_0}
\]  

The $F_1$ and $F_{-1}$ terms can be suggestively identified with the sums of indices for monodromy defects of parameters 1 and 0, and 0 and $-1$ respectively. This suggests that the Schur index of $S_2$ should be thought of as the sum of the Schur indices of three monodromy defects, of monodromy parameters 1, 0 and $-1$ respectively. The corresponding module should be some interesting deformation of that sum of spectral flowed vacuum modules.

The pattern continues for higher $r$: the regulated Schur indices of $S_r$ take the form of a sum of the Schur indices of $r + 1$ monodromy defects, of monodromy parameters $-\frac{r}{2}, -\frac{r}{2} + 1, \ldots, -\frac{r}{2}$. This agrees very nicely with the class S description of the defects: all these defects admit a twisted F-term deformation parameter $z$ of scaling dimension $\frac{1}{2}$ which triggers an RG flow to such a sum of $r + 1$ independent monodromy defects.

There are two ways we can go beyond the Schur index calculation and probe aspects of the surface defects which tease out the physical difference between $S_r$ and a direct sum of monodromy defects: we can either compute the full superconformal index or analyze in more detail the chiral algebra modules.

### 4.2.1 Full index calculations

The full superconformal index of the $D_4$ Argyres-Douglas theory has been computed in [46]. Using this result together with Higgsing we present in appendix B the full superconformal index of the canonical surface defect of the free hypermultiplet. Amusingly, the answer is still given as a sum of $r + 1$ terms, though we do not expect each individual term to have a separate physical meaning.

We leave a full discussion of the full index to future work. It would be nice to identify the operators dual to the expected chiral and twisted chiral deformations.
We focus here on the Macdonald limit of this index. From the general formula (B.6) we specialize by taking $p = 0$. This limit is significant because it receives contributions from the same set of operators as the Schur index which is obtained when $t = q$. The explicit expression for the canonical defect is

\[ I_S(q, a, \epsilon) = \frac{1 - \epsilon^2}{(ae; q)_\infty (a^{-1}e; q)_\infty}, \quad \epsilon \equiv \sqrt{\frac{t}{q}}. \]  

(4.18)

As compared to the Schur limit, the index is now completely well-defined.

Interestingly, the Macdonald index (4.18) also has a natural interpretation in terms of the twisted module $R_\lambda$ introduced in section 4.1. As before, the fugacity $a$ measures the charge associated to the current $J(w) = -: \gamma \beta :$ of the symplectic bosons. The chiral algebra interpretation of the additional fugacity $\epsilon$, on the other hand, requires further explanation. Let us pick a reference state, say, $|m = 0\rangle$, in the $R_\lambda$ module at level zero. We can then construct the rest of the states in the $R_\lambda$ module by acting $\beta_{n \leq 0} \cdot \gamma_{n \leq 0}$ on $|m = 0\rangle$. Given a state in $R_\lambda$, the fugacity $\epsilon$ measures the minimal number of modes $\beta_{n \leq 0} \cdot \gamma_{n \leq 0}$ that is required to construct this state from the reference state $|m = 0\rangle$.

With this chiral algebra definition of the $\epsilon$ fugacity, we see immediately that the Macdonald index (4.18) is the character of $R_\lambda$ (for generic $\lambda$). The terms $(ae; q)_\infty$ and $(a^{-1}e; q)_\infty$ in the denominator come from the modes $\beta_{n \leq 0}$ and $\gamma_{n \leq 0}$, respectively. The term $1 - \epsilon^2$ in the numerator comes from the relation in the module that $0 \psi$ equals to $\psi$ itself up to a nonzero multiplicative constant. The chiral algebra interpretation of the Macdonald index of the more general Argyres-Douglas theories has been explored in [60].

4.2.2 Quantum Drinfeld-Sokolov reduction

According to the general discussion of section 3.3, it should be possible to build explicitly the modules for all the $S_r$ defects by qDS reduction of the spectral flow of the vacuum module of the $D_4$ theory.

The $D_4$ theory chiral algebra is a WZW model $SU(3)_{\frac{3}{2}}$. The Higgs branch RG flow corresponds to doing a qDS reduction based on an $SU(2)_{\frac{1}{2}}$ subalgebra. At general level, the qDS reduction of an $SU(3)_\kappa$ Kac-Moody algebra based on an $SU(2)_\kappa$ sub-algebra would give a vertex algebra generated by the following currents:

- A $U(1)$ current of level $\frac{2}{3} \kappa$, arising from the $U(1)$ generator in $SU(3)$ which commutes with the $SU(2)$ subgroup.

- A Virasoro generator of central charge $c = 23 - \frac{24}{\kappa+3} - 6(\kappa + 3)$, all which is left of the $SU(2)$ currents.

- Two dimension $\frac{3}{2}$ bosonic fields, arising from the two $SU(3)$ generators of charge $\frac{1}{2}$ under the Cartan of $SU(2)$.

- Two dimension $\frac{1}{2}$ bosonic fields, arising from the two $SU(3)$ generators of charge $-\frac{1}{2}$ under the Cartan of $SU(2)$. 

- 17 -
The two dimension $\frac{1}{2}$ fields are free symplectic bosons which are usually stripped off, leaving the Bershadsky-Polyakov algebra $W_{3}^{(2)}$. At the special level we are interested in, though, the qDS reduction collapses to the symplectic bosons and all other currents are functions of the symplectic bosons themselves.

Notice that the symplectic bosons $\beta, \gamma$ arise directly from the two corresponding currents $J^{+1}, J^{+2}$, as the BRST current is just $c(J^{++} - 1)$ and thus the BRST charge commutes with these currents. The OPE of these two currents is

$$J^{+1}(w)J^{+2}(0) \sim \frac{J^{++}(0)}{w}$$

but $J^{++}$ is BRST equivalent to 1 and the OPE reduces to the free symplectic boson OPE.

In order to produce “vortex” modules associated to vortex defects, we start from a spectral flow module associated to the Cartan of SU(2), with the property that the current $J^{++}$ which will be set to 1 by the qDS reduction has a pole of order $r$ while the current $J^{-}$ has a zero of order $r$. Inspection of the character shows clearly that the highest weight vector of the vortex module is the combination of the spectral flowed image of the vacuum for both the current algebra and the auxiliary ghost system, so that the $b$ ghost also has a pole of order $r$ and the $c$ ghost has a zero of order $r$.

The symplectic bosons have both poles of order $\frac{r}{2}$ in the spectral flowed sector. Looking at the character of the qDS reduction, organized by $U(1)$ charge sector,

$$\chi_{r}[qDS_{2}\circ SU(3)_{\frac{r}{2}}] = (-1)^{r} \sum_{n=-\infty}^{\infty} \frac{x_{n}q^{-n^{2}}}{(q)_{\infty}} \sum_{k=0}^{\infty} (1-q^{(2k+1+n)(r+1)})q^{\frac{1}{2}(2k+n-\frac{r}{2})(2k+n+1-\frac{r}{2})}$$

we recognize for each $n$ the leading term in the character $q^{\frac{r(r-2)}{8} + |n| \frac{1-r}{2}}$ corresponding to states of the form $\beta_{r-1}^{n} |r\rangle$ and $\gamma_{r-1}^{n} |r\rangle$.

We leave a determination of the full structure of the vortex modules to future work. For $r = 1$, the very fact that the $U(1)_{-1}$ charges are integral strongly suggests that we are looking at the symmetric Ramond module $R_{\lambda=0}$.

5 Argyres-Douglas theories

In this section we discuss canonical surface defects of the Argyres-Douglas theories. Our aim is to compute surface defect Schur indices and to describe the associated chiral algebra modules. We apply both the IR formula for the 2d-4d index as well as the Higgsing procedure. We will consider Argyres-Douglas theories whose BPS quivers are Dynkin diagrams of simply-laced Lie algebras $G$ (also known as the $(A,G)$ Argyres-Douglas in the notations of [30].) We will demonstrate that the surface defect indices we obtain equal the characters of the associated chiral algebra. The simplest examples are the $A_{2n}$ Argyres-Douglas theory, where the surface defect indices of different vortex numbers reproduce all and only the $n + 1$ characters of the $(2,2n + 3)$ Virasoro minimal model. In the case when some flavor symmetries are broken by the defect (e.g. the canonical surface defect of the $A_{3}$ Argyres-Douglas theory), the surface defect index turns out to be a twisted character of the chiral algebra.
5.1 $A_{2n} : (2, 2n + 3)$ Virasoro minimal models

5.1.1 Indices from BPS states: the $A_2$ theory

As a warm up, let us consider the simplest nontrivial Argyres-Douglas theory whose BPS quiver is the $A_2$ Dynkin diagram. It has a complex one-dimensional Coulomb branch and no flavor symmetry. The associated chiral algebra is the (2,5) Virasoro minimal model with central charge $c = -22/5$, a.k.a. the Lee-Yang model [7]. The (2,5) Virasoro minimal model contains one non-vacuum module whose primary $\Phi_{1,2}$ has conformal dimension $h = -1/5$. Let us first compute the canonical surface defect index using our IR formula from the BPS states.

In one chamber there are two pure 4d BPS particles $\gamma^1$, $\gamma^2$ with Dirac pairing $(\gamma^1, \gamma^2) = +1$. In the presence of the canonical surface defect, there is a subchamber where in addition we have one $C$ charge neutral 2d soliton interpolating the two vacua with vanishing 4d charge and degeneracy $\mu_{12}(0,0) = 1$, and one 2d BPS particle living in the second vacuum with $\omega_2(\gamma^1, 1) = -1$ [23]. Their central charge phases in increasing order are

$$\gamma_{12}, \gamma^1, \gamma^2.$$  \hspace{1cm} (5.1)

where $\gamma^1$ collectively stands for the 2d particle living in the second vacuum and the 4d particle, both with charge $\gamma^1$. Their corresponding wall-crossing factors are

$$S_{12;0} = \begin{pmatrix} 1 & -1 \\ 0 & 1 \end{pmatrix}, \quad K^{2d}_{\gamma^1} = \begin{pmatrix} 1 & 0 \\ 0 & 1 + q^2 X_{\gamma^1} \end{pmatrix}, \quad K^{4d}_{\gamma^1} = \begin{pmatrix} E_q(X_{\gamma^1}) & 0 \\ 0 & E_q(X_{\gamma^1}) \end{pmatrix},$$ \hspace{1cm} (5.2)

$$S_{21;0} = \begin{pmatrix} 1 & 0 \\ 1 & 1 \end{pmatrix}, \quad K^{2d}_{\gamma^1} = \begin{pmatrix} 1 & 0 \\ 0 & (1+q^{-1/2} X_{\gamma^1})^{-1} \end{pmatrix}, \quad K^{4d}_{\gamma^1} = \begin{pmatrix} E_q(X_{\gamma^1}) & 0 \\ 0 & E_q(X_{\gamma^1}) \end{pmatrix}.$$  \hspace{1cm} (5.3)

Note that the antiparticle in 2d has opposite $C$ charge and degeneracy, $\omega_2(-\gamma^1, -1) = 1$. We will often combine $K^{2d}_{\gamma^1}$ with $K^{4d}_{\gamma^1}$ to form

$$K_{\gamma^1} \equiv K^{2d}_{\gamma^1} K^{4d}_{\gamma^1} = \begin{pmatrix} E_q(X_{\gamma^1}) & 0 \\ 0 & E_q(q X_{\gamma^1}) \end{pmatrix}.$$ \hspace{1cm} (5.4)

Let us apply our IR formula (2.16) for the 2d-4d Schur index in this chamber,

$$\mathcal{I}_{2d}(q) = (q) \sum_{\ell_1, \ell_2 = 0}^{\infty} \frac{q^{\ell_1 + \ell_2 + \ell_1 \ell_2}}{(q \ell_1(q) \ell_2)^2} (2 - q^{\ell_1}) = 1 + q + q^2 + q^3 + 2q^4 + 2q^5 + 3q^6 + \cdots.$$ \hspace{1cm} (5.5)

The final answer is to insert $2 - q^{\ell_1}$ into the double-sum formula of the Schur index without the defect, which is [7]

$$\mathcal{I}_{A_2}(q) = (q) \sum_{\ell_1, \ell_2 = 0}^{\infty} \frac{q^{\ell_1 + \ell_2 + \ell_1 \ell_2}}{(q \ell_1(q) \ell_2)^2}.$$ \hspace{1cm} (5.5)
We have checked that the surface defect index $I_S(q)$ agrees with the character of the $h = -1/5$ primary $\Phi_{1,2}$ in the $(2,5)$ minimal model to $\mathcal{O}(q^{100})$,
\[
I_S(q) = \chi_{(1,2)}^{(2,5)}(q) .
\] (5.6)

Here the character $\chi_{(s,r)}^{(p,p')}(q)$ of the $\Phi_{s,r}$ primary $(1 \leq s \leq p - 1, 1 \leq r \leq p' - 1)$ in the $(p,p')$ Virasoro minimal model is given by (e.g. see [61])
\[
\chi_{(s,r)}^{(p,p')}(q) = q^{-(p-p' r)^2 (p-p')^2} \left( K_{s,r}^{(p,p')}(q) - K_{s,r}^{(p,p')}(q) \right)
\] (5.7)
where
\[
K_{s,r}^{(p,p')}(q) = q^{-\frac{2}{r}} \sum_{n \in \mathbb{Z}} q^{(2 p - p' n + p r - p' r s)^2} .
\] (5.8)

We have normalized the character to start from 1. Note the following identification between the primaries in the minimal models, $\Phi_{s,r} = \Phi_{p-s,p'-r}$. In particular, the $(2, 2n+3)$ Virasoro minimal model has $n+1$ primaries (including the vacuum), $\Phi_{1,r}$ with $r = 1, 2, \ldots, n+1$.

We will reproduce this answer by Higgsing the $D_5$ Argyres-Douglas theory when we discuss the general case of $A_{2n}$.

5.1.2 A relation between surfaces and lines

In [30, 41], a surprising relation between the line defect index and the chiral algebra characters was found in many examples. It was observed that even though the line defects do not preserve the chiral algebra cohomology, their Schur indices can often be written as linear combinations of characters of the associated chiral algebra. The simplest example is the $A_2$ Argyres-Douglas theory, where the line defect index is found to be equal to
\[
I_L(q) = q^{-\frac{1}{2}} \chi_{(1,1)}^{(2,5)}(q) - q^{-\frac{1}{2}} \chi_{(1,2)}^{(2,5)}(q) ,
\] (5.9)
where $\chi_{(1,1)}^{(2,5)}(q)$ and $\chi_{(1,2)}^{(2,5)}(q)$ are respectively the characters for the vacuum and weight $h = -1/5$ primary in the $(2,5)$ Virasoro minimal models.

This observation can be explained by a relation between the surface defects, whose indices are the chiral algebra characters, and the line defects as elaborated in section 4 of [24]. More explicitly, we can cut open a surface defect by inserting an identity interface. We can then unwrap the surface defect into a sum of line defects. A powerful advantage of the infrared formula (2.16) for the surface defect index is that it respects this unwrapping process. In this section we illustrate this procedure in the $A_2$ Argyres-Douglas theory and derive the relation (5.9).

Let us repeat the IR calculation in an alternative way such that the connection to the line defects will become clear. Let us apply the refined wall-crossing formula $S_{12,\gamma} K_{\gamma'} = K_{\gamma'} S_{12,\gamma} + S_{12,\gamma'} S_{12,\gamma}$ derived in section 3.3.1 of [24] to rewrite the quantum spectrum generator as,
\[
S_{\theta,0}^{2d,4d} = S_{12,0} K_{\gamma 1} K_{\gamma 2} = K_{\gamma 1} S_{12,\gamma 1} S_{12,0} K_{\gamma 2} = K_{\gamma 1} S_{12,\gamma 1} K_{\gamma 2} S_{12,0} .
\] (5.10)
Next, we apply the same basic wall-crossing formula to group the 4d K-factors together,

\[ S^{2d;4d}_{0,\vartheta+\pi} = K_{\gamma_1} K_{\gamma_2} S_{12;\gamma_1+\gamma_2} S_{12;0} S_{12;0}. \]  

(5.11)

Now we can rewrite our infrared formula for the surface defect index as,

\[ I_\mathcal{B}(q) = (q)^2 \text{Tr} \left[ \Sigma^{2d} K_{\gamma_1} K_{\gamma_2} K_{\gamma_1} K_{\gamma_2} \right], \]  

where

\[ \Sigma^{2d} = S_{12;\gamma_1+\gamma_2} S_{12;0} S_{0;21} = \begin{pmatrix} -q^{\frac{1}{2}} F(L_4) & -1-q^{\frac{1}{2}} F(L_4) \\ 1 & 1 \end{pmatrix}, \]

\[ K_{\gamma_1} K_{\gamma_2} K_{\gamma_1} K_{\gamma_2} = \begin{pmatrix} \mathcal{O}(X_{\gamma_1}, X_{\gamma_2}) & 0 \\ 0 & \mathcal{O}(q X_{\gamma_1}, X_{\gamma_2}) \end{pmatrix}. \]  

(5.12)

(5.13)

Here \( \Sigma^{2d} \) is the product of the S-factors coming from 2d solitons and \( \mathcal{O}(X_{\gamma_1}, X_{\gamma_2}) \) is the 4d quantum spectrum generator over the full central charge plane,

\[ \mathcal{O}(X_{\gamma_1}, X_{\gamma_2}) \equiv S_{\vartheta+\pi}(q) S_{\vartheta+\varpi+2\pi}(q) = E_q(X_{-\gamma_1}) E_q(X_{-\gamma_2}) E_q(X_{\gamma_1}) E_q(X_{\gamma_2}). \]  

(5.14)

Above we show the dependence on \( X_{\gamma_i} \) explicitly because sometimes they might be shifted by powers of \( q \) due to the 2d BPS particles. Finally, \( F(L_4) = X_{\gamma_1} + X_{\gamma_1+\gamma_2} \) is the generating function for the bulk line defect \( L_4 \) in the \( A_2 \) Argyres-Douglas theory \([29, 34]\).

From the above expression, we see that the surface defect index naturally decomposes into two terms, each of which can be interpreted as a line defect index,

\[ I_\mathcal{B}(q) = (q)^2 \text{Tr} \left[ \left( 1-q^{\frac{1}{2}} F(L_4) \right) \mathcal{O}(X_{\gamma_1}, X_{\gamma_2}) \right] \]

\[ = I(q) - q^{\frac{1}{2}} I_L(q), \]  

(5.15)

where in the last line we used the infrared formula for the line defect Schur indices \([41]\).

Finally by noting that \( I_\mathcal{B}(q) = \chi^{(2,5)}_{(1,2)}(q) \) and \( I(q) = \chi^{(2,5)}_{(1,1)}(q) \), the above relation exactly reproduces the observation (5.9) in \([41]\) that the line defect Schur indices are linear combinations of the chiral algebra characters.

### 5.1.3 Indices from BPS states: the \( A_{2n} \) theory

The more general \( A_{2n} \) Argyres-Douglas theory has the \( A_{2n} \) Dynkin diagram as its BPS quiver. It has a complex \( n \)-dimensional Coulomb branch and no flavor symmetry. The associated chiral algebra is the \((2, 2n+3)\) Virasoro minimal model \([7]\). We will see that the canonical surface defect index agrees with the character for the primary \( \Phi_{1,2} \) in all cases. The other characters in the minimal model will arise from other surface defect indices.

As studied in \([23]\), there is one chamber on the Coulomb branch where the 2d-4d BPS spectrum is (in increasing phase order)

\[ \gamma_{12}, \gamma_1, \gamma_2, \gamma_3, \ldots, \gamma_{2n-1}, \gamma_1^2, \gamma_2^2, \gamma_3^2, \ldots, \gamma_{2n}^2. \]  

(5.16)
Here $\gamma^i$'s are a basis for the charge lattice and have the following Dirac pairings,
\begin{equation}
\langle \gamma^i, \gamma^j \rangle = (-1)^{i+1}(\delta_{i,j+1} + \delta_{j,i-1}).
\end{equation}
There is a $C$ charge neutral 2d soliton interpolating between the two vacua and a unit $C$
charge 2d particle with 4d gauge charge $\gamma^1$ living in the second vacuum $\omega_2(\gamma^1, 1) = -1$.

Applying our IR formula for the canonical surface defect index, we obtain
\begin{equation}
\mathcal{I}_S(q) = (q)^{2n} \text{Tr} \left[ S_{\gamma_12} \prod_{I \text{ odd}} \mathcal{K}_{\gamma_I} \prod_{J \text{ even}} \mathcal{K}_{\gamma_J} S_{\gamma_21} \prod_{I \text{ odd}} \mathcal{K}_{-\gamma_I} \prod_{J \text{ even}} \mathcal{K}_{-\gamma_J} \right]
\end{equation}
\begin{equation}
= (q)^{2n} \text{Tr} \left[ E_q(X_{\gamma_1}) \prod_{I \text{ odd,} -1} E_q(X_{\gamma_I}) \prod_{J \text{ even}} E_q(X_{\gamma_J}) E_q(X_{-\gamma_I}) \prod_{I \text{ odd,} -1} E_q(X_{-\gamma_J}) - E_q(q X_{\gamma_1}) \prod_{I \text{ odd,} -1} E_q(X_{\gamma_I}) \prod_{J \text{ even}} E_q(X_{\gamma_J}) E_q(q^{-1} X_{-\gamma_I}) \prod_{I \text{ odd,} -1} E_q(X_{-\gamma_J}) \prod_{J \text{ even}} E_q(X_{-\gamma_J}) 
+ E_q(q X_{\gamma_1}) \prod_{I \text{ odd,} -1} E_q(X_{\gamma_I}) \prod_{J \text{ even}} E_q(X_{\gamma_J}) E_q(q^{-1} X_{-\gamma_I}) \prod_{I \text{ odd,} -1} E_q(X_{-\gamma_J}) \prod_{J \text{ even}} E_q(X_{-\gamma_J}) \right]
\end{equation}
\begin{equation}
= (q)^{2n} \sum_{\ell_1, \cdots, \ell_{2n} = 0}^{\infty} \frac{q^{\sum_{i=1}^{2n} \ell_i + \sum_{i=1}^{2n-1} \ell_i \ell_{i+1}}}{\prod_{i=1}^{2n}[(q) \ell_i]^2} (2 - q^{\ell_1}).
\end{equation}
The final answer is to insert $2 - q^{\ell_1}$ into the multiple-sum formula of the Schur index
without the defect $\mathcal{I}_{A_{2n}}(q)$, which is [7]
\begin{equation}
\mathcal{I}_{A_{2n}}(q) = (q)^{2n} \sum_{\ell_1, \cdots, \ell_{2n} = 0}^{\infty} \frac{q^{\sum_{i=1}^{2n} \ell_i + \sum_{i=1}^{2n-1} \ell_i \ell_{i+1}}}{\prod_{i=1}^{2n}[(q) \ell_i]^2}.
\end{equation}
We have checked that the answer agrees with the character of the $\Phi_{1,2}$ primary for the
$(2, 2n + 3)$ Virasoro minimal model to high orders in $q$,
\begin{equation}
\mathcal{I}_S(q) = \chi_{(1,2)}^{(2,2n+3)}(q).
\end{equation}

\subsection{5.1.4 Indices from Higgsing}

The $A_{2n}$ Argyres-Douglas theory can be realized by Higgsing the $D_{2n+3}$ theory, and the
vortex surface defects in the former theory are realized by turning on position-dependent
Higgs field in the latter. Consequently, the $A_{2n}$ vortex surface defect indices can be obtained
by taking the residues (in the flavor fugacity) of the $D_{2n+3}$ Schur index [20]. In addition to
the canonical surface defect (which has unit vortex number), we will compute the indices for
surface defects of any vortex number, which in turn reproduce all and only the characters
of the associated $(2, 2n + 3)$ Virasoro minimal model.

The Schur index of the $D_{2n+3}$ Argyres-Douglas theory is the vacuum character of
$\hat{\text{SU}}(2)_{4n+1}_{2n+3}$ [36],
\begin{equation}
\mathcal{I}_{D_{2n+3}}(q, x) = \prod_{k=1}^{\infty} \frac{1}{(1 - q^k)(1 - x^2 q^k)(1 - x^{-2} q^k)} \sum_{n=0}^{\infty} (-1)^n q^{\frac{2n+1}{3}} - x^{-\frac{2k-1}{3}} q^{\frac{k(k+1)}{3}} (2n+3). 
\end{equation}
Notice the structure of an alternating sum of characters of Weyl modules of spin 0, 1, 2, etc.
The SU(2) WZW currents are associated to the moment map operators for the SU(2) flavor symmetry of the theory. We Higgs the theory by giving nilpotent vevs to these moment maps. This corresponds to the poles in the SU(2) flavor fugacity $x$ at $x^{\pm 1} = q^{(s+1)/2}$ for $s$ a non-negative integer in the index and to the usual qDS reduction in the chiral algebra.

As a warm up, let us start by considering the residue at the lowest order pole $x = q^{1/2}$. This corresponds to turning on a constant Higgs vev of the $D_{2n+3}$ theory. In the IR the theory flows to the $A_{2n}$ theory without vortices. The Schur index of the IR theory is captured by the residue at $x = q^{1/2}$ (normalizing by $2(q^2)_{\infty}$),

$$I_{A_{2n}}(q) = 2(q^2)_{\infty} \operatorname{Res}_{x \to q^{1/2}} \frac{1}{x} I_{D_{2n+3}}(q, y)$$

$$= \frac{1}{\prod_{k=2}^{\infty}(1-q^{k})} \sum_{k=0}^{\infty} (-1)^k \frac{q^{(k+1)(2n+3)}}{q^{1/2} - q^{-1/2}} q^{-k} q^{-k+1/2} q^{-k+3/2}$$

$$= \frac{1}{(q^2)_{\infty}} \sum_{\ell = -\infty}^{\infty} \left(q^{2\ell(2n+3)+2n+1}(1-q^{\ell}) - q^{2\ell(2n+3)+2n+5}(1+)\right) = \lambda_{(1,1)}^{(2,2n+3)}(q). \quad (5.22)$$

The answer is precisely the vacuum character for the $(2, 2n + 3)$ Virasoro minimal model, which is indeed the Schur index of the $A_{2n}$ Argyres-Douglas theory [7].

It is interesting how the sum over characters of Weyl modules of spin $k$ for the Kac-Moody algebra maps to a sum over characters of Virasoro modules with a single null vector at level $2k + 1$, which is then reorganized to the alternating sum over character of Virasoro Verma modules which defines the $(2, 2n + 3)$ Virasoro vacuum character. It should be interesting to follow this correspondence at the level of the qDS reduction of the chiral algebra.

More generally, the residue at $x = q^{(r+1)/2}$ corresponds to turning on a position-dependent Higgs vev. In the IR the system flows to the $A_{2n}$ Argyres-Douglas theory with a surface defect, denoted by $S_r$, of vortex number $r$. The residue of the $D_{2n+3}$ index at $x = q^{(r+1)/2}$ then computes its surface defect index,

$$I_{S_r}(q) = 2(-1)^{p_1} q^{p_2} \frac{1}{x} \operatorname{Res}_{x \to q^{(r+1)/2}} \frac{1}{x} I_{D_{2n+3}}(q, x)$$

$$= (-1)^{p_1 + r} q^{p_2} \frac{1}{x} \left(1 - q^{(r+1)/2}\right) \sum_{\ell = -\infty}^{\infty} \left(q^{2\ell(2n+3)+2n+1}(1-q^{\ell}) - q^{2\ell(2n+3)+2n+5}(1+)\right)$$

$$= \frac{(-1)^{p_1} q^{p_2}}{(q^2)_{\infty}} \sum_{\ell = -\infty}^{\infty} \left(q^{2\ell(2n+3)+2n+1}(1-q^{\ell}) - q^{2\ell(2n+3)+2n+5}(1+)\right), \quad (5.23)$$

where the overall factor $2(-1)^{p_1 + r} q^{p_2} \frac{1}{x}$ is inserted to normalized the index to start from 1. The subscript $r$ labels the vortex number of the surface defect. Here $p_1 = \left\lfloor \frac{r}{2n+3} \right\rfloor$ and $p_2 = \frac{1}{2} \left( \frac{r}{2n+3} \right) \left(2n + 3\right) - 2n - 1 + 2\bar{r}$. We have defined $\bar{r} \equiv r \mod (2n + 3)$.

Remarkably, these vortex surface defect indices reproduce all and only the $n + 1$ characters of the $(2, 2n + 3)$ Virasoro minimal model,

$$I_{S_r}(q) = \lambda_{(1,1,\bar{r}+1)}^{(2,2n+3)}(q), \quad \bar{r} \equiv r \mod (2n + 3). \quad (5.24)$$

In particular, the surface defect index has a periodicity of $2n + 3$ in the vortex number $r$, and a reflection symmetry $\bar{r} \leftrightarrow 2n + 1 - \bar{r}$, which mirrors the reflection symmetry of the
Table 1. The vortex surface defect indices in the Schur limit for the $A_2$ Argyres-Douglas theory. $\chi^{(2,5)}_{(1,1)}$ and $\chi^{(2,5)}_{(1,2)}$ denote the characters of the vacuum and the $h = -1/5$ primary, respectively. The defect Schur index in this case is periodic in the vortex number $r$ with period 5. It also enjoys a reflection symmetry $\bar{r} \leftrightarrow 3 - \bar{r}$, where $\bar{r} \equiv r \mod 5$.

| Vortex Number $r$ | 0   | 1   | 2   | 3   | 4   | 5   | ⋯ |
|-------------------|-----|-----|-----|-----|-----|-----|----|
| $I_{S_r}(q)$      | $\chi^{(2,5)}_{(1,1)}$ | $\chi^{(2,5)}_{(1,2)}$ | $\chi^{(2,5)}_{(1,1)}$ | $\chi^{(2,5)}_{(1,2)}$ | 0   | $\chi^{(2,5)}_{(1,1)}$ | ⋯ |

$(p, p')$ minimal model primaries $\Phi_{s,r} = \Phi_{p-s, p'-r}$. It vanishes if $\bar{r} + 1$ is a multiple of $2n + 3$. Note that the canonical surface defect discussed previously has unit vortex number $r = 1$ and gives rise to the character for $\Phi_{1,2}$. The resulting behavior of the vortex surface defect indices for the $A_2$ theory is illustrated in table 1.

In the special case $n = 0$, the bulk theory is empty, and the defect Schur index is either 1 or 0 depending on the vortex number $r$:

$$
I_{S_r}(q) = \begin{cases} 
1, & r = 0, 1 \mod 3, \\
0, & r = 2 \mod 3. 
\end{cases}
$$

(5.25)

The previous discussion shows that the 2d-4d Schur index cannot completely distinguish between the vortex surface defects $S_r$. This then presents the question: are these vortex defects physically the same, or is the 2d-4d Schur index simply too coarse an observable? We can probe this question by computing more refined invariants of the defects.

- We can look at the details of the qDS reduction to probe if the corresponding chiral algebra modules also have the periodicity and reflection symmetry manifested by the characters.

- We can compute the full superconformal index of the surface defect if we are given the full superconformal index of the $D_{2n+3}$ theory.

These two ideas are not unrelated. Indeed, the Macdonald limit of the superconformal index receives contributions from the same set of operators as the Schur index [3]. Thus if the Macdonald indices are distinct, the chiral algebra modules are also distinct. Motivated by this, in appendix A we calculate the full index in a very special example: the reduction of the $D_3$ theory to a trivial theory. That example already shows the lack of periodicity and reflection symmetry in the Macdonald defect index suggesting that the chiral algebra modules are indeed distinct. It would be interesting to reproduce this directly from qDS reduction.

5.2 $A_{2n+1}$ : $W_{n+1}^{(2)}$ algebras

The 4d $A_{2n+1}$ Argyres-Douglas superconformal theory has a complex $n$-dimensional Coulomb branch and an U(1) flavor symmetry. The flavor symmetry is enhanced to SU(2) in the cases of $n = 0, 1$. In particular, the $A_1$ Argyres-Douglas theory is the free hypermultiplet discussed in detail in section 4.

---

8Technically, this has only been demonstrated for the index without a surface defect. It is natural to expect that it continues to hold in the presence of defects as well.
The chiral algebra of the $A_{2n+1}$ Argyres-Douglas theory is the $W_{n+1}^{(2)}$ algebra at level $k = -(n+1)^2/(n+2)$ [18, 38]. The $W_{n+1}^{(2)}$ algebra at level $k$ is the quantum Hamiltonian reduction corresponding to a certain non-principal embedding of SU(2) into SU$(n+1)_k$ [62]. The series of $W_{n+1}^{(2)}$ algebras at level $k = -(n+1)^2/(n+2)$ for $n = 0, 1, 2, \cdots$ is studied in [38, 63].

Let us discuss the first few cases of the $A_{2n+1}$ chiral algebras.

5.2.1 $A_3 : \widehat{\text{SU}(2)}_{-\frac{4}{3}}$

The $A_3$ chiral algebra is $\widehat{\text{SU}(2)}_{-\frac{4}{3}}$, whose vacuum character has been matched with the Schur index of the $A_3$ Argyres-Douglas theory [7, 36]. Recall that the nonvanishing commutation relations in the $\widehat{\text{SU}(2)}_k$ Kac-Moody algebra are

\[
\begin{align*}
[J^+_n, J^-_m] &= 2J^n_{m+n} + kn\delta_{n,-m}, \\
[J^3_n, J^\pm_m] &= \pm J^\pm_{n+m}, \\
[J^3_n, J^3_m] &= \frac{k}{2}n\delta_{n,-m}.
\end{align*}
\]

(5.26)

The $\widehat{\text{SU}(2)}_k$ has a spectral flow symmetry labeled by $\eta \in \mathbb{R}$ that leaves the commutation relations invariant. The spectral flow by $\eta$ units acts on the currents as

\[
J^3_n \rightarrow J^3_n' = J^3_n + \frac{k}{2}\eta\delta_{n,0}, \quad J^\pm_n \rightarrow J^\pm_n' = J^\pm_n \pm \eta.
\]

(5.27)

Let $\lambda$ be the Dynkin label for the finite SU(2) of a highest weight state and $h$ its conformal weight determined by the Sugawara construction.\footnote{For an untwisted module, it is given by $h = \frac{\lambda(\lambda+1)}{4(k+2)}$.} We can then produce a new highest weight module $(\lambda', h')$ from an existing one $(\lambda, h)$ by $\eta$ units of spectral flow, where

\[
\lambda' = \lambda + \frac{1}{2}\eta, \quad h' = h + \frac{1}{2}\lambda + \frac{1}{4}\eta^2.
\]

(5.28)

In particular, a spectral flow by a half integral amount shift $J^3_n$ to be half-integrally moded and leaves $J^\pm_n$ integrally moded. Modules of the half-integrally spectral-flowed $\widehat{\text{SU}(2)}_k$ algebra will be called the twisted modules. Note that the twisted $\widehat{\text{SU}(2)}_k$ does not contain the finite SU(2) Lie algebra as its subalgebra since the $J^0_0$ zero modes are lifted under spectral flow.

The $\widehat{\text{SU}(2)}_{-\frac{4}{3}}$ twisted module that will be related to the canonical surface defect is the $\eta = -1/2$ spectral-flowed twisted module of an admissible untwisted module with $(\lambda = -\frac{2}{3}, h = -\frac{1}{3})$. The highest weight of this twisted module then has $\lambda = 0$ and $h = -\frac{5}{12}$ by (5.28). The character of the untwisted $(\lambda = -\frac{2}{3}, h = -\frac{1}{3})$ module is (see, for example, [61])

\[
\chi(\lambda = -\frac{2}{3}, h = -\frac{1}{3}) (q, w) = \frac{w^{-2/3} 1 + \sum_{k=1}^{\infty} (-1)^k w^{2k} q^{\frac{k}{3}(3k-1)} + w^{-2k} q^{\frac{k}{3}(3k+1)} }{1 - w^2 \prod_{k=1}^{\infty} (1 - q^k)(1 - w^2 q^k)(1 - w^{-2} q^k)},
\]

(5.29)
where \( w \) is the SU(2) flavor fugacity. This character has appeared in the study of line defect indices of the \( A_3 \) Argyres-Douglas theory [41]. Using (5.28), it follows that the character \( \chi^\text{tw}_{(\lambda=0,h=-\frac{5}{12})}(q,w) \) for the twisted module is given by (up to an overall factor) replacing \( w \rightarrow wq^{\frac{1}{2}} \) in the untwisted character,

\[
\chi^\text{tw}_{(\lambda=0,h=-\frac{5}{12})}(q,w) = \frac{1 + \sum_{k=1}^{\infty}(-1)^k(w^{2k} + w^{-2k})q^{\frac{4k^2}{27}}}{\prod_{k=1}^{\infty}(1-q^k)(1-w^2q^{k-1/2})(1-w^{-2}q^{k-1/2})},
\]

where we have normalized the twisted character to start from 1. Notice the denominator representing all twisted and untwisted current algebra modes and the numerator encoding the structure of null vectors.

We will see that the canonical surface defect index in the \( A_3 \) Argyres-Douglas theory, computed both from the IR formula and the Higgsing procedure, equals the above twisted character.

### 5.2.2 \( A_5 \) : Bershadsky-Polyakov algebra \( W_3^{(2)} \)

The Bershadsky-Polyakov algebra \( W_3^{(2)} \) at level \( k \) [64, 65] contains a weight one bosonic generator \( J(z) \), two weight \( \frac{3}{2} \) bosonic generators \( G^\pm (z) \), and one weight 2 bosonic generator \( T(z) \). Note that this algebra almost has the same generators as the \( \mathcal{N} = 2 \) Virasoro algebra except that in the case of \( W_3^{(2)} \), all the generators are bosonic. The central charge is

\[
c = 25 - \frac{24}{k+3} - 6(k+3).
\]

The OPEs are

\[
\begin{align*}
J(z)J(0) &\sim \frac{2k+3}{3z^2}, \\
G^+(z)G^-(0) &\sim \frac{(k+1)(2k+3)}{z^3} + \frac{3(k+1)}{z^2}J(0) \\
&\quad + \frac{1}{z} \left[ 3 : JJ : (0) - (k+3)T(0) + \frac{3(k+1)}{2}\partial J(0) \right],
\end{align*}
\]

with the remaining OPEs determined by U(1) charge conservation, \( J(z) \) and \( G^\pm(z) \) being Virasoro primaries of weight 1 and 3/2, respectively, and \( G^\pm(z) \) being current algebra primaries of charge ±1. Note that the Bershadsky-Polyakov algebra is nonlinear because of the \( :JJ : \) term on the righthand side of the \( G^+(z)G^-(0) \) OPE.

The \( W_3^{(2)} \) algebra, similar to the \( \mathcal{N} = 2 \) Virasoro algebra, has a spectral flow symmetry labeled by \( \eta \in \mathbb{R} \), which acts as

\[
\begin{align*}
G^\pm_r &\rightarrow G^\pm_{r'=r+\eta}, \\
J_n &\rightarrow J'_n = J_n + \frac{2k+3}{3} - \eta \delta_{n,0}, \\
L_n &\rightarrow L'_n = L_n + \eta J_n + \frac{2k+3}{6} - \eta^2 \delta_{n,0}.
\end{align*}
\]

---

**JHEP05(2017)140**
In particular, half-integer units of spectral flow will shift the moding of $G^\pm_r$ from half-integers to integers, and vice versa. If $G^\pm_r$ are integrally (half-integrally) moded, we will call the algebra and its modules twisted (untwisted).

The $A_5$ chiral algebra is the Bershadsky-Polyakov algebra $W_3^{(2)}$ at level $k = -9/4$, and hence $c = -23/2$ [18, 38]. The U(1) current $J(z)$ descends from the 4d U(1) flavor symmetry current of the $A_5$ Argyres-Douglas theory. To provide evidence for the above claim, one should check the $W_3^{(2)}$ vacuum character equals the $A_5$ Schur index without any defect. Using the Weaver Mathematica package of [66], we compute the first few terms of the vacuum character (turning off the U(1) flavor fugacity)

$$\chi_0^{W_3^{(2)}}(q, x = 1) = 1 + q + 2q^3 + 3q^2 + 4q^3 + 7q^3 + 8q^4 + O(q^5).$$  \hspace{1cm} (5.34)

This nicely agrees with the $A_5$ Schur index derived in [7, 36],

$$\mathcal{I}_{A_5}(q, x = 1) = \chi_0^{W_3^{(2)}}(q, x = 1).$$  \hspace{1cm} (5.35)

As we will see in this section, both the twisted and the untwisted characters of the $W_3^{(2)}$ algebra will appear as the surface defect indices of the $A_5$ Argyres-Douglas theory.

5.2.3 Indices from BPS states

The 2d-4d BPS spectrum for the $A_{2n+1}$ Argyres-Douglas theory with the canonical surface defect is analogous to the $A_{2n}$ Argyres-Douglas theory. The Dirac pairings between the 4d charges are again (5.17). There is a flavor symmetry U(1), which is enhanced to SU(2) for the $A_3$ theory, associated with the lattice vector $\gamma_f$ defined as

$$\gamma_f = \sum_{i=0}^{n} (-1)^i \gamma_{2i+1}. \hspace{1cm} (5.36)$$

We will be working in a chamber where there is a $C$ charge neutral 2d soliton between the two vacua with degeneracy $\mu_{12}(0,0) = 1$, as well as a unit $C$ charge 2d BPS particle with 4d charge $\gamma^1$ living in the second vacuum $\omega_2(\gamma^1, 1) = -1$. The 2d-4d BPS spectrum is (in increasing phase order)

$$\gamma_{12}, \gamma^1, \gamma^3, \ldots, \gamma^{2n-1}, \gamma^2, \gamma^4, \ldots, \gamma^{2n-2}, \hspace{1cm} (5.37)$$

where again $\gamma^1$ collectively stand for the 4d particle and the 2d particle living in the second vacuum. The IR calculation proceeds exactly as in the $A_{2n}$ case and we obtain

$$q_{(2n)}^2 \sum_{\begin{substack}{k_i, \ldots, k_{2n+1} = 0 \cr \ell_1, \ldots, \ell_{2n+1}} \end{substack}}^{\infty} \frac{(-1)^{\sum_{i=1}^{2n+1}(k_i+\ell_i)} q^{\frac{1}{2} \sum_{i=1}^{2n+1}(k_i+\ell_i)+\sum_{j=1}^{n} \ell_{2j}(\ell_{2j-1}+\ell_{2j+1})}}{\prod_{i=1}^{2n+1}(q)k_i(q)\ell_i} \hspace{1cm} (5.38)$$

$$\times \left[ (-1)^{n+1} x \right]^{\ell_1-k_1} \left(1 + q^{\ell_1-k_1} - q^{\ell_1} \right) \prod_{i=1}^{n} \delta_{k_{2i}, \ell_{2i}} \prod_{j=1}^{n} \delta_{(-1)^i+1, \ell_1+k_{2j+1}, (-1)^j+1, \ell_1+\ell_{2j+1}}.$$
The U(1) flavor fugacity $x$ is normalized to be the trace of the flavor generator as

$$\text{Tr}[X_{ij}] = (-1)^{n+1}x. \quad (5.39)$$

Finally we should shift the flavor fugacity by

$$x \to xq^{-\frac{1}{2}}. \quad (5.40)$$

As discussed in section 3.2, this is modifying the surface defect in the above calculation by a monodromy twist. In this way we obtain the canonical surface defect for the $A_{2n+1}$ Argyres-Douglas theory which resides in the twisted sector. Hence

$$i^\mathcal{S}(q,x) = (q)^{2n} \sum_{\ell_1,\cdots,\ell_{2n+1}, k_1,\cdots,k_{2n+1}=0}^{\mathcal{C}_{2n+1}} \frac{(-1)^{n+1}}{q^\frac{\ell_1+k_1}{2} + q^\frac{k_1}{2} - q^\frac{\ell_1+k_1}{2}} \prod_{i} \delta_{\ell_{2i},\ell_{2i+1}} \prod_{j} \delta_{(-1)^{j+1}k_1+k_{2j+1},(-1)^{j+1}k_{2j+1}}. \quad (5.41)$$

The final answer is to insert $q^\frac{\ell_1-k_1}{2} + q^\frac{k_1}{2} - q^\frac{\ell_1+k_1}{2}$ into the multiple-sum formula of the $A_{2n+1}$ Schur index $i^\mathcal{S}_{A_{2n+1}}(q,x)$ without the defect in [7].

For the $A_3$ Argyres-Douglas theory, the U(1) flavor symmetry is enhanced to SU(2), and we will replace the U(1) flavor fugacity $x$ by $w^2$ so that the character of the $n$-dimensional representation of SU(2) is $\chi_n(w) = (w^n - w^{-n})/(w - w^{-1})$. The first few terms of the canonical surface defect index are

$$i^\mathcal{S}(q,w) = 1 + (w^2 + w^{-2})q^2 + (w^4 + 1)q^2 + (w^6 + 2w^2 + 2w^{-2} + w^{-6})q^2 + (w^8 + 2w^4 + 4 + 2w^{-4} + w^{-8})q^2 + (w^{10} + 2w^6 + 5w^2 + 5w^{-2} + 2w^{-6} + w^{-10})q^2 + (w^{12} + 2w^8 + 5w^4 + 8 + 5w^{-4} + 2w^{-8} + w^{-12})q^3 + (w^{14} + 2w^{10} + 5w^6 + 10w^2 + 10w^{-2} + 5w^{-6} + 2w^{-10} + w^{-14})q^7 + \mathcal{O}(q^4). \quad (5.42)$$

We have checked that the above surface defect index agrees with the twisted character of $\text{SU}(2)_{-\frac{3}{2}}$ with $\lambda = 0$ (5.30) to $\mathcal{O}(q^6)$,

$$i^\mathcal{S}(q,w) = \chi_{(\lambda=0,h=-\frac{3}{4})}(q,w). \quad (5.43)$$

Note that the coefficients of the index can not be written as non-negative sums of SU(2) characters because the SU(2) flavor symmetry is broken by the canonical surface defect. Correspondingly, the twisted SU(2)$_{-\frac{3}{4}}$ does not contain the finite SU(2) Lie algebra as its subalgebra because the zero modes $J_{ij}^5$ are lifted under spectral flow.

Moving on to the $A_5$ case, the first few terms of the canonical surface defect index are

$$i^\mathcal{S}(q,x) = 1 + (x^2 + 2x + 1)q + (x^4 + 2x^2 + 4 + 2x^{-1} + x^{-2})q^2 + (x^3 + 2x^2 + 5x + 8 + 5x^{-1} + 2x^{-2} + x^{-3})q^3 + (x^4 + 2x^3 + 5x^2 + 10x + 15 + 10x^{-1} + 5x^{-2} + 2x^{-3} + x^{-4})q^4 + (x^5 + 2x^4 + 5x^3 + 10x^2 + 19x + 26 + 19x^{-1} + 10x^{-2} + 5x^{-3} + 2x^{-4} + x^{-5})q^5 + \mathcal{O}(q^6). \quad (5.44)$$
which agrees with the twisted character with \( L_0 = -\frac{5}{16}, J_0 = 0, G^+_0 = 0 \) of the Bershadsky-Polyakov algebra \( W^{(2)}_3 \) at level \( k = -\frac{3}{4} \). We have checked the above claim using the \texttt{Weaver Mathematica} package of \cite{66} to \( O(q^5) \) with the flavor fugacity \( x \) off,

\[
I_{\mathcal{S}}(q, x = 1) = \chi_{L_0 = -\frac{2}{n}, J_0 = 0}(q, x = 1) . \tag{5.45}
\]

To sum up, we computed the canonical surface defect indices (5.41) of the \( A_{2n+1} \) Argyres-Douglas theories from the 2d-4d BPS states. We checked that the answers nicely reproduce the twisted characters of the associated chiral algebra \( W^{(2)}_{n+1} \) for small \( n \). In the following we will compute the more general surface defect indices in these theories from the Higgsing procedure and match with the other characters of the associated chiral algebra.

5.2.4 Indices from Higgsing

The \( A_{2n+1} \) Argyres-Douglas theory can be obtained by Higgsing the \( D_{2n+4} \) theory. At the level of the index, the \( A_{2n+1} \) vortex surface defect indices of all vortex numbers can be computed from the residues of the \( D_{2n+4} \) Schur index without the defect. The Schur index of the \( D_{2n+4} \) theory is \cite{36}

\[
I_{D_{2n+4}}(q, x_1, x_2)
= \left( \frac{I_{\text{vect}}^{SU(2)}(x_2)}{(q)_{\infty}} \right)^{-\frac{1}{2}} \sum_{k=0}^{\infty} \frac{1}{x_2 - x_2^{-1}} \sum_{p=\pm 1} \left[ q^{\frac{(2k^2 + 2k + 1)(n+2)}{2} x_2^{2k+2} x_1^p} - q^{\frac{(2k^2 + 4k + 1)(n+2)}{2} x_2^{2k-2} x_1^p} \right] x_2 x_1^p
+ q^{(n+2)(k+1)} \chi_{2k+1}(x_2) \right) , \tag{5.46}
\]

where

\[
\left( \frac{I_{\text{vect}}^{SU(2)}(x_2)}{(q)_{\infty}} \right)^{-\frac{1}{2}} = \frac{1}{(q)_{\infty}} \prod_{m=1}^{\infty} \frac{1}{1 - q^m x_2^2 (1 - q^m x_2^{-2})} , \tag{5.47}
\]

and \( \chi_n(x_2) \) is the SU(2) character for the \( n \)-dimensional representation. The \( D_{2n+4} \) Argyres-Douglas theory has SU(2) \( \times U(1) \) flavor symmetry. Here \( x_1 \) is the U(1) fugacity and \( x_2 \) is the SU(2) fugacity. The \( D_{2n+4} \) index has poles in the SU(2) fugacity at \( x_2 = q^{\frac{r+1}{2}} \left( r = 0, 1, 2, \cdots \right) \), whose residues give the vortex defect indices of the \( A_{2n+1} \) theory. It follows that the 2d-4d Schur index of a surface defect \( S_r \) of vortex number \( r \) in the \( A_{2n+1} \) theory is

\[
I_{S_r}(q, x) = 2(q)_\infty^2 (-1)^{p_1 + r} q^{\frac{p_2 - r(r+1)}{2}} \text{Res}_{x_2 = q^{\frac{r+1}{2}} x_2} \frac{1}{x_2} I_{D_{2n+4}}(q, x, x_2) \tag{5.48}
\]

\[
= (-1)^{p_1} (q)_\infty^2 q^{p_2} (1 - q^{r+1}) \sum_{k=0}^{\infty} \left[ \frac{1}{q^{\frac{r+1}{2}} - q^{-\frac{r+1}{2}}} \sum_{p=\pm 1} \left[ q^{\frac{(2k^2 + 4k + 1)(n+2) + (k+1)(r+1)}{2} x_2^p} - q^{(n+2)(k+1)(r+1)} \frac{q^{\frac{(2k^2 + 4k + 1)(n+2)}{2} x_2^p} - q^{(n+2)(k+1)(r+1)} x_2^p}{q^{\frac{r+1}{2}} x_2^p} \right] + q^{(n+2)(k+1)} \frac{q^{\frac{(2k^2 + 1)(n+2)}{2} x_2^p} - q^{-(k+1)(r+1)} x_2^p}{q^{\frac{r+1}{2}} x_2^p} \right]
\]
where \( p_1 = \left\lfloor \frac{r}{n+2} \right\rfloor \) and \( p_2 = (n+2) \left( \left\lfloor \frac{r}{2n+4} \right\rfloor \right)^2 - (n+1 - r) \left\lfloor \frac{r}{2n+4} \right\rfloor \). Here \( \bar{r} \equiv r \mod (2n+4) \).

The factor \( 2(q)^2 \zeta_\infty(-1)^{p_1+r} q^{p_2-\frac{r(r+1)}{2}} \) is inserted to normalize the index to start from 1. Similar to the case in the \( A_{2n} \) theory discussed in section 5.1.4, the vortex surface defect index \( T_{S_0}(q, x_1) \) is periodic in \( r \) with periodicity \( 2n+4 \), i.e. \( T_{S_0}(q, x_1) = T_{S_0}(q, x_1) \). It also enjoys the reflection symmetry \( \bar{r} \leftrightarrow 2n+2-r \). Hence \( T_{S_0}(q, x_1) = T_{S_{2n+2-r}}(q, x_1) \).

Furthermore, it vanishes for \( \bar{r} = n+1 \) and \( \bar{r} = 2n+3 \).

We expect that the phenomena we saw for the free hypermultiplet will happen generically and that the periodicity and zeroes of the Schur indices of vortex defects in \( A_{2n+1} \) theories do not actually not hold at the level of chiral algebra modules, similarly to the case of \( A_{2n} \) theories. Indeed this is born out by the Macdonald index calculations of appendix B.

For the \( A_3 \) theory, we have checked to high orders of the \( q \)-expansion that (recall that in the \( A_3 \) theory it is more natural to use the \( SU(2) \) fugacity \( w = \sqrt{q} \))

\[
T_{S_0}(q, w) = \begin{cases} 
\chi_0^{SU(2)-4/3} (q, w) & \text{if } r = 0, 4 \mod 6, \\
\chi_{(\lambda = 0, h = -\frac{5}{12})}^{1w} (q, w) & \text{if } r = 1, 3 \mod 6, \\
0 & \text{if } r = 2, 5 \mod 6, 
\end{cases}
\]

where \( \chi_0^{SU(2)-4/3} (q, w) \) and \( \chi_{(\lambda = 0, h = -\frac{5}{12})}^{1w} (q, w) \) are the vacuum character (see, for example, [7, 36] for the explicit expression) and the twisted character (5.30) of \( SU(2)_{-\frac{4}{3}} \), respectively. In particular, the surface defect with unit vortex number \( r = 1 \) is the canonical surface defect and the above results reproduce the answer (5.43) obtained from the IR formula (2.16).

For the \( A_5 \) case, we have checked to high orders of the \( q \)-expansion that

\[
T_{S_0}(q, x) = \begin{cases} 
\chi_0^{W_3^{(2)}} (q, x) & \text{if } r = 0, 6 \mod 8, \\
\chi_{L_0=-\frac{5}{12}, J_0=0}^{1w} (q, x) & \text{if } r = 2, 4 \mod 8, \\
\chi_{L_0=-\frac{1}{2}, J_0=0}^{1w} (q, x) & \text{if } r = 1, 5 \mod 8, \\
0 & \text{if } r = 3, 7 \mod 8, 
\end{cases}
\]

where \( \chi_0^{W_3^{(2)}} (q, x) \) and \( \chi_{L_0=-\frac{5}{12}, J_0=0}^{1w} (q, x) \) are the aforementioned vacuum (5.34) and twisted characters (5.45) of \( W_3^{(2)} \) at \( k = -\frac{9}{4} \), respectively. The other index \( \chi_{L_0=-\frac{1}{2}, J_0=0}^{1w} (q, x) \) is a another untwisted character of \( W_3^{(2)} \) with \( L_0 = -\frac{1}{2} \) and \( J_0 = 0 \). We computed this untwisted character again using the \texttt{Weaver Mathematica} package [66] to \( \mathcal{O}(q^4) \) (with the \( U(1) \) fugacity off) and verify it agrees with \( T_{S_0}(q, x = 1) \) for \( r = 1, 5 \mod 8 \).

A The full superconformal index for vortex defects in an empty 4d theory

In this appendix we compute the full, three-variable superconformal index for the surface defects in an empty 4d theory. Even though the 4d theory is empty, we can introduce surface defects with interacting degrees of freedom, and hence make the 2d-4d system nontrivial. We will focus on vortex defects \( S_r \) arising from turning on a position-dependent Higgs field in the UV \( D_3 \cong A_3 \) Argyres-Douglas theory, and then flowing to the IR empty bulk theory with surface defects. The superconformal indices for these vortex defects can be obtained as the residues of the full superconformal index of the \( D_3 \) theory without the defect \cite{20} (see section 2.3 for a more detailed discussion).

The full superconformal index of the \( D_3 \) theory is \cite{45, 46}\footnote{There are two equivalent expressions for the index depending on whether we think of it as the \( D_3 \) or \( A_3 \) theory. The pole structure is more manifest for the purpose of Higgsing if we view it as a \( D_3 \) theory.}

\[
\mathcal{I}^{D_3}(p, q, t, a) = \frac{\kappa}{2} \frac{\Gamma \left( \frac{(pq/t)^\frac{3}{2}}{2\pi i z} \right) \Gamma \left( \frac{(pq/t)^{\frac{3}{2}}}{2\pi i z} \right)}{\Gamma \left( \frac{(pq/t)^{\frac{3}{2}}}{2\pi i z} \right) \Gamma \left( \frac{(pq/t)^{\frac{3}{2}}}{2\pi i z} \right)} \int \frac{dz}{2\pi i z} \frac{\Gamma \left( \frac{z^\pm (pq)^{\frac{1}{2}} t^{\frac{3}{2}}}{2^\frac{3}{2}} \right)}{\Gamma \left( \frac{z^\pm (pq)^{\frac{1}{2}} t^{\frac{3}{2}}}{2^\frac{3}{2}} \right)} \Gamma \left( \frac{z^\pm (pq)^{-\frac{1}{2}} t^{\frac{3}{2}}}{2^\frac{3}{2}} \right),
\]

where

\[
\Gamma(z) = \prod_{m,n=0}^\infty \frac{1 - z^{-1} p^{m+1} q^{n+1}}{1 - z p^m q^n},
\]

is the elliptic gamma function \cite{67–69} and \( \kappa = (p; p)_\infty (q; q)_\infty \). Here \( a \) is the fugacity for the SU(2) flavor symmetry.

Among other poles in \( z \), let us consider the following two at

\[
z = a^{-1} (pq)^\frac{1}{2} t^{\frac{3}{2}} q^{m_1}, \quad \text{and} \quad \frac{z = (pq)^\frac{1}{2} t^{\frac{3}{2}} q^{-m_2}}{n},
\]

for some non-negative integers \( m_1, m_2 \). These two poles come from \( \Gamma \left( \frac{z^{-1} a^{-1} (pq)^{\frac{1}{2}} t^{\frac{3}{2}}}{2^\frac{3}{2}} \right) \) and \( \Gamma \left( \frac{z (pq)^{-\frac{1}{2}} t^{\frac{3}{2}}}{2^\frac{3}{2}} \right) \), respectively. This pair of poles collide when

\[
a = t q^r, \quad r = m_1 + m_2 \geq 0.
\]

At this value of \( a \) the contour in \( z \) is pinched and produces a simple pole of the \( D_3 \) index in \( a \). The residue of this pole gives the surface defect index with vortex number \( r \) in the IR.
empty 4d theory. The residue can be obtained by first taking the residue of the integrand in (A.1) with respect to \( z \), and then take the residue in \( a \) at (A.4). The poles in \( z \) that contribute to this index are labeled by a partition \( \{ m_1, m_2 \} \) of the vortex number \( r \).

Let us consider the contribution from the pole in (A.3) labeled by \( \{ m_1, m_2 \} \). The residue of the divergent elliptic gamma function is

\[
\text{Res}_{z=a^{-1}(pq)^{1_{3}}tq^{m_1}} \frac{1}{z} \Gamma \left( z^{-1} a^{-1}(pq)^{1_{3}}tq^{m_1} \right) = \frac{1}{(q;q)(p;p)} \prod_{u=0}^{m_1-1} \prod_{m_0}^{\infty} \frac{1}{1 - p^{m+1}q^{m+1}}.
\]

(A.5)

The residue of the integrand at \( z = a^{-1}(pq)^{1_{3}}tq^{m_1} \) is then

\[
\text{Res}_{z=a^{-1}(pq)^{1_{3}}tq^{m_1}} \text{Int}(\mathcal{I}_{D^3}) = \frac{\kappa}{2} \Gamma \left( (pq)/t^{3} \right) \Gamma \left( (pq)/t^{3} \right) \Gamma \left( (a^{-2}pq)^{2m_1} \right) \Gamma \left( a^{2}(pq)^{-3}t^{-3}q^{-2m_1} \right)
\]

\[
\times \Gamma \left( (pq)t^{3}q^{m_1} \right) \Gamma \left( (a^{-2}pq)t^{3}q^{m_1} \right) \times \Gamma \left( (a^{-1}pq)t^{3}q^{m_1} \right) \Gamma \left( aq^{-m_1} \right)
\]

\[
\times \Gamma \left( (a^{-1}pq)t^{3}q^{m_1} \right) \Gamma \left( a(a^{-1}pq)^{-3}t^{3}q^{m_1} \right) \left( 1 \right) \prod_{u=0}^{m_1-1} \prod_{m_0}^{\infty} \frac{1}{1 - p^{m+1}q^{m+1}}.
\]

(A.6)

Next, we take the residue of the above expression at \( a = tq^r \) with \( r = m_1 + m_2 \)

\[
\mathcal{A}_{m_1,m_2} = \text{Res}_{a=tq^r} \frac{1}{a} \text{Int}(\mathcal{I}_{D^3}) = \text{Res}_{a=tq^r} \frac{1}{a} \text{Res}_{z=a^{-1}(pq)^{1_{3}}tq^{m_1}} \text{Int}(\mathcal{I}_{D^3})
\]

\[
= \frac{1}{2 \mathcal{I}_V} \prod_{m_0=0}^{\infty} \left( \prod_{u=0}^{m_1-1} \prod_{m_0}^{m_2-1} \frac{1}{1 - p^{m+1}q^{m+1}} \right)
\]

\[
\times \frac{1}{\Gamma \left( (pq)/t^{3}q^{2m_2} \right)} \Gamma \left( (pq)/t^{3} \right) \Gamma \left( (pq)/t^{3}q^{m_1} \right) \Gamma \left( (pq)/t^{3} \right)
\]

\[
\times \frac{1}{\Gamma \left( (pq)/t^{3}q^{m_1+2m_2} \right)} \Gamma \left( (pq)/t^{3}q^{m_1} \right) \Gamma \left( (pq)/t^{3}q^{m_1} \right) \Gamma \left( (pq)/t^{3}q^{m_1+2m_2} \right)
\]

\[
\times \frac{1}{\Gamma \left( (pq)/t^{3}q^{2m_2} \right)} \Gamma \left( (pq)/t^{3}q^{m_1+2m_2} \right) \Gamma \left( (pq)/t^{3}q^{m_1+2m_2} \right) \Gamma \left( (pq)/t^{3}q^{m_1+2m_2} \right).
\]

(A.7)

where

\[
\mathcal{I}_V = \kappa \Gamma(pq/t)
\]

is the superconformal index of an U(1) vector multiplet. We have used

\[
\Gamma(z)\Gamma(z^{-1}pq) = 1
\]

(A.9)

to simplify the index.

There is one more step we need to do to obtain the surface defect index. The Higgsed theory in the IR has decoupled 2d degrees of freedom contributing to the index by

\[
R_{0,r} = \prod_{u=0}^{r-1} \prod_{m=0}^{\infty} \frac{1 - t^{-1}q^{-u+1}p^{m+1}}{1 - q^{-u+1}p^{m+1}} = \prod_{u=0}^{r-1} \prod_{m=0}^{\infty} \frac{1 - t^{-1}q^{-u+1}p^{m+1}}{1 - q^{-u+1}p^{m+1}}.
\]

(A.10)
The surface defect index \( I_{S_r} \) with vortex number \( r \) is the residue of the \( D_3 \) index at \( a = tq^r \) by summing over the contributions \( A_{m_1,m_2} \) with the decoupled sectors factored out,

\[
I_{S_r}(p, q, t) = 2 \mathcal{I}_V R_{0,r}^{-1} \mathrm{Res}_{a = tq^r} \frac{1}{a} \mathcal{I}^{D_3} = 2 \mathcal{I}_V R_{0,r}^{-1} \sum_{m_1, m_2 \geq 0, m_1 + m_2 = r} A_{m_1, m_2}. \tag{A.11}
\]

### A.1 The trivial defect

Let us consider the case without the defect in an empty 4d bulk theory. This 2d-4d system is completely empty and we expect the index to be 1. Indeed, the only contribution to the index comes from the pole labeled by \( \{m_1 = 0, m_2 = 0\} \), which is

\[
I(p, q, t) = 1, \tag{A.12}
\]

as expected.

### A.2 The canonical surface defect \( r = 1 \)

Let us move on to consider the \( r = 1 \) vortex defect, i.e. the canonical surface defect, in an empty 4d theory. It is known that the 2d theory living on the defect is a twisted Landau-Ginzburg theory with a cubic twisted superpotential \cite{23}. Since the 4d theory is empty, the surface defect index in this case is nothing but the NS-NS elliptic genus of this Landau-Ginzburg theory.

The surface defect index receives contribution from \( \{m_1 = 1, m_2 = 0\} \) and \( \{m_1 = 0, m_2 = 1\} \):

\[
2 \mathcal{I}_V R_{0,1}^{-1} A_{1,0} = \prod_{m = 0}^{\infty} \frac{1}{(1 - t^{-1} p^m)(1 - t p^m)} \frac{\Gamma \left( \frac{(pq/t)^{\frac{1}{2}}}{} \right)}{\Gamma \left( (pq/t)^{\frac{1}{2}} q^{-1} \right)} \frac{\Gamma \left( (pq/t)^{\frac{1}{2}} \right)}{\Gamma \left( (pq/t)^{\frac{1}{2}} q \right)} \tag{A.13}
\]

\[
2 \mathcal{I}_V R_{0,1}^{-1} A_{0,1} = \prod_{m = 0}^{\infty} \frac{1}{(1 - t^{-1} p^m)(1 - t p^m)} \frac{\Gamma \left( (pq)^{-\frac{1}{2}} t q^2 \right)}{\Gamma \left( (pq)^{-\frac{1}{2}} t q^2 \right)} \frac{\Gamma \left( (pq)^{-\frac{1}{2}} \right)}{\Gamma \left( (pq)^{-\frac{1}{2}} t q^2 \right)} \frac{\Gamma \left( (pq/t)^{\frac{1}{2}} \right)}{\Gamma \left( (pq/t)^{\frac{1}{2}} \right)}. \tag{A.14}
\]

Let us simplify the above expression using

\[
\frac{\Gamma(zq)}{\Gamma(z)} = (z;p)_\infty (z^{-1} p;p)_\infty = \theta_p(z), \tag{A.15}
\]

where\(^{12}\)

\[
\theta_p(x) = \frac{1}{(p;p)_\infty} \sum_{n \in \mathbb{Z}} p^{n(n-1)/2} (-x)^n. \tag{A.16}
\]

\(^{12}\)Note that \( \theta_p(x) \) is related to the Jacobi theta function

\[
\theta_1(p, x) = -i p^{\frac{1}{2}} x^{\frac{1}{2}} \prod_{k=1}^{\infty} (1 - p^k)(1 - xp^k)(1 - x^{-1} p^{k-1}), \tag{A.17}
\]

by

\[
\theta_p(x) = \frac{-i p^{\frac{1}{2}} x^{\frac{1}{2}}}{(p;p)_\infty} \theta_1(p, x). \tag{A.18}
\]
In terms of $\theta_p$, the index can be simplified as
\[
I_{S_1}(p, q, t) = \frac{\theta_p(p^\frac{1}{2}q^{-\frac{1}{2}}t^{-\frac{1}{2}}) \theta_p(t^2)}{\theta_p(p^\frac{3}{2}q^{-\frac{3}{2}}t^{-\frac{3}{2}}) \theta_p(t)} + \frac{\theta_p(p^{-\frac{1}{2}}q^{-\frac{1}{2}}t^{\frac{1}{2}}) \theta_p(p^{-\frac{1}{2}}q^{\frac{1}{2}}t^{\frac{1}{2}})}{\theta_p(p^\frac{3}{2}q^{-\frac{3}{2}}t^{-\frac{3}{2}}) \theta_p(p^{-\frac{1}{2}}q^{\frac{1}{2}}t^{\frac{1}{2}})}. \tag{A.18}
\]

Now we want to compare this answer to the elliptic genus of the twisted Landau-Ginzburg model. To do that, we need to translate the 4d fugacities $p, q, t$ into the 2d fugacities $q, y, e$ in the NS-NS elliptic genus below:
\[
\mathcal{G}(q, y, e) = \text{Tr}_{NSNS} \left[ (-1)^{F_{2d}} q^{L_0} y^{K_0} q^{L_0-J_0/2} e^C \right], \tag{A.19}
\]
where recall that $e$ is a universal flavor fugacity coupled to the charge $C = R - M_\perp$ (2.2). In this case the twisted Landau-Ginzburg model has no flavor symmetry so the answer should be independent of $e$. The 4d fugacities are related to the 2d ones as (see, for example, [24, 48])
\[
p = q, \quad q = q^{\frac{1}{2}} e y, \quad t = q e y^2. \tag{A.20}
\]

In terms of the 2d fugacities, the surface defect index becomes
\[
I_{S_1}(p, q, t) = \frac{\theta_q(q^{-\frac{1}{2}} y^{-\frac{1}{2}} e^{-1}) \theta_q(q^2 y^4 e^2)}{\theta_q(q^{-\frac{1}{2}} y^{-\frac{1}{2}} e^{-2}) \theta_q(q y^2 e)} + \frac{\theta_q(q^{\frac{3}{2}} y^{\frac{3}{2}} e) \theta_q(q^{\frac{3}{2}} y^{\frac{3}{2}} e^2)}{\theta_q(q^{-\frac{1}{2}} y^{-\frac{1}{2}} e^{-1}) \theta_q(q^{\frac{1}{2}} y^{\frac{1}{2}} e^2)}. \tag{A.21}
\]

One can check that the above answer has the same series expansion as the elliptic genus of the twisted Landau-Ginzburg model with cubic superpotential [70],
\[
\mathcal{G}(q, y) = y q^{\frac{1}{2}} \frac{\theta_q(q^{-\frac{1}{2}} y^{-\frac{1}{2}})}{\theta_q(q^{-\frac{1}{2}} y^{\frac{1}{2}})}. \tag{A.22}
\]
In particular, the answer in this case does not depend on the universal flavor fugacity $e$. We have thus obtained the expected full superconformal index for the canonical surface defect in the empty 4d theory from Higgsing $D_3$ Argyres-Douglas theory.

### A.3 The vortex defect with $r = 2$

For the vortex number $r = 2$ defect, we saw that the Schur index is zero in (5.25), which is consistent with the fact that the chiral algebra is trivial. Here we will see that it has a nontrivial Macdonald index.

In this case we need to add up the contributions from $\{m_1 = 2, m_2 = 0\}$, $\{m_1 = 1, m_2 = 1\}$, and $\{m_1 = 0, m_2 = 2\}$. For simplicity, we will only compute the Macdonald limit of the index. The three contributions in this limit become
\[
2 I_V R^{-1}_{0,2} A_{2,0} = \frac{(1 + t)(1 - t^2 q)}{(1 - t q)},
\]
\[
2 I_V R^{-1}_{0,2} A_{1,1} = -t(1 + t q) \frac{1 - q^{-2}}{1 - q^{-1}}, \tag{A.23}
\]
\[
2 I_V R^{-1}_{0,2} A_{0,2} = t^2 q.
\]
Adding all these contributions together, we obtain the \( r = 2 \) vortex defect index in an empty 4d theory in the Macdonald limit,

\[
I_{S_2}(q,t) = \frac{1 - tq^{-1}}{1 - qt}.
\]  

(A.24)

Indeed it vanishes in the Schur limit \( t = q \). The Macdonald index takes the form of a character with one bosonic mode and one fermionic mode. It is intriguing that even though the chiral algebra is trivial in this case, there is still a nontrivial Macdonald index.

### A.4 The vortex defect with \( r = 3 \)

For the \( r = 3 \) vortex defect index, there are four contributions from the poles labeled by \( \{ m_1 = 3, m_2 = 0 \}, \{ m_1 = 2, m_2 = 1 \}, \{ m_1 = 1, m_2 = 2 \}, \{ m_1 = 0, m_2 = 3 \} \). Adding all the above together, we obtain the Macdonald index for the \( r = 3 \) vortex defect,

\[
I_{S_3}(q,t) = \frac{q^3t + q^2 - qt - t}{q^2 - q^3t}.
\]  

(A.25)

This reduces to \(-1/q\) in the \( t = q \) Schur limit. Note that the Macdonald index does not enjoy the periodicity \( \tilde{r} \leftrightarrow 1 - \tilde{r} \) of the Schur index, where \( \tilde{r} = r \mod 3 \).

### B The full superconformal index for vortex defects of the hypermultiplet

In this appendix we extend the computation of the full, three-variable surface defect index in the previous appendix to the free 4d hypermultiplet theory. Even though the 4d bulk theory is free, the coupled 2d-4d system is generally strongly interacting and has interesting nontrivial defect indices as we saw in section 4.

We again focus on vortex defects \( S_r \) arising from turning on a position-dependent Higgs field in the \( D_4 \) Argyres-Douglas theory, and then flowing to the IR free hypermultiplet theory with surface defects. As discussed in section 2.3, the surface defect index of a free hypermultiplet can be computed from the residues of the index for the \( D_4 \) theory without the defect.

Let us motivate our consideration of superconformal indices beyond the Schur limit. First, recall that in (4.4), we saw that the canonical surface defect (i.e. vortex number \( r = 1 \)) is naively 0. We would like to understand whether this implies that the spectrum of the 2d-4d supersymmetric operators is empty, or there is an infinite degeneracy leading to 0 after certain regularization. As discussed before, the correspondence with the chiral algebra suggests the latter interpretation is the correct one. In this appendix we explicit compute the full superconformal index of the canonical surface defect and show that it is nonzero, and thus confirming the picture from the chiral algebra.

Secondly, for the surface defect with vortex number \( r = 2 \), its Schur index was shown to agree with the original Schur index of the free hypermultiplet without defects. We would like to verify that this \( r = 2 \) vortex defect is physically distinct from the trivial defect, even though they share the same spectrum of 2d-4d Schur operators. In the following we will compute the full superconformal index of this \( r = 2 \) vortex defect and show that it
differs from the index of the free hypermultiplet in the absence of defects. These analyses give a concrete example of two physically distinct surface defects sharing the same 2d-4d Schur operator spectrum, and hence correspond to the same module in the associated chiral algebra.

Let us embark on the calculation. The full superconformal index of the $D_4$ theory has been conjectured to be \cite{45, 46},
\[
I^{D_4}(p, q, t, a_1, a_2) = \frac{\kappa}{2} \frac{\Gamma \left( \frac{pq}{t} \right)}{\Gamma \left( \frac{pq}{t} \right)} \int \frac{dz}{2\pi iz} \frac{\Gamma \left( z^{2}(pq)^{\frac{1}{2}}t^{-\frac{1}{2}} \right)}{\Gamma \left( z^{2} \right)} \\
\times \Gamma \left( (za_1a_2^3)^{\pm}(pq)\frac{1}{2} \right) \Gamma \left( (z^{-1}a_1a_2^3)^{\pm}(pq)\frac{1}{2} \right) \\
\times \Gamma \left( (za_1a_2^{-1})^{\pm}(pq)^{-\frac{1}{2}}t^\frac{3}{2} \right) \Gamma \left( (z^{-1}a_1a_2^{-1})^{\pm}(pq)^{-\frac{1}{2}}t^\frac{3}{2} \right),
\]
where $a_1$ and $a_2$ are the fugacities for the SU(3) flavor symmetry. Incidentally, $\Gamma(z)$ is the superconformal index of a half-hypermultiplet.

Among other poles in $z$, let us consider the following two
\[
z = a_1a_2^3(pq)^{-\frac{1}{2}}t^{-\frac{1}{2}}q^{-m_1}, \quad z = a_1a_2^{-1}(pq)^{-\frac{1}{2}}t^\frac{3}{2}q^{m_2},
\]
for some non-negative integers $m_1, m_2$. They come from $\Gamma \left( (z^{-1}a_1a_2^3)^{-1}(pq)t^\frac{1}{2} \right)$ and $\Gamma \left( (z^{-1}a_1a_2^{-1})(pq)^{-\frac{1}{2}}t^\frac{3}{2} \right)$, respectively. This pair of poles collide when
\[
a_2 = t^\frac{1}{4}q^\frac{1}{2}, \quad r = m_1 + m_2 \geq 0.
\]
At this value of $a_2$ the contour in $z$ is pinched and produce a simple pole of the $D_4$ index in $a_2$. As in the previous appendix, this residue for the $D_4$ index gives the index of the surface defect of vortex number $r$ in the free hypermultiplet theory.

Let us consider the contribution from the pole (B.2) in $z$ labeled by \{m_1, m_2\}. A similar calculation as in the previous appendix shows that the contribution to the residue of the $D_4$ index at $a_2 = t^\frac{1}{4}q^\frac{1}{2}$ from the pole \{m_1, m_2\} is
\[
A_{m_1, m_2} = \text{Res}_{a_2=t^\frac{1}{4}q^\frac{1}{2}} \frac{1}{a_2} \text{Res}_{z=a_1a_2^{-1}(pq)^{-\frac{1}{2}}t^\frac{3}{2}q^{m_2}} \text{Int}(I^{D_4}) \\
= \frac{1}{2T_v} \prod_{m=0}^{\infty} \left( \prod_{u=0}^{m+1} \frac{1}{\left( 1-p^m q^{-u-1} \right) \left( 1-p^{m+1} q^{u+1} \right)} \prod_{u=0}^{m+1} \frac{1}{\left( 1-p^m q^{-u} \right) \left( 1-p^{m+1} q^{u+1} \right)} \right) \\
\times \Gamma \left( \frac{pq}{t} \right) \Gamma \left( \frac{pq}{t} \right) \Gamma \left( \frac{1}{2} t^\frac{3}{2} q^{-\frac{m_1+3m_2}{2}} \right) \Gamma \left( \frac{1}{2} t^\frac{3}{2} q^{-\frac{m_1-3m_2}{2}} \right) \\
\times \Gamma \left( \frac{1}{2} t^\frac{3}{2} q^{-\frac{m_1+3m_2}{2}} \right) \Gamma \left( \frac{1}{2} t^\frac{3}{2} q^{-\frac{m_1-3m_2}{2}} \right) \Gamma \left( \frac{1}{2} t^\frac{3}{2} q^{m_1} \right) \\
\times \Gamma \left( \frac{1}{2} t^\frac{3}{2} q^{-\frac{m_1+3m_2}{2}} \right) \Gamma \left( \frac{1}{2} t^\frac{3}{2} q^{m_1} \right),
\]
where $a_1$ and $a_2$ are the fugacities for the SU(3) flavor symmetry. Incidentally, $\Gamma(z)$ is the superconformal index of a half-hypermultiplet.
B.1 The trivial defect

Let us test the above formula by considering the case without surface defects, i.e. $r = m_1 = m_2 = 0$. We find

$$I(p, q, t, a_1) = \frac{1}{\theta_p(t)\theta_p(a_1^2 t)} \frac{1}{\theta_p(p)\theta_p(a_1^2 p t)} \frac{1}{\theta_p(q)\theta_p(a_1^2 q t)} = 2 \Gamma(a_1^2 t \frac{1}{2}) \Gamma(a_1^{-2} t \frac{1}{2}), \quad (B.5)$$

which is indeed the superconformal index of a free hypermultiplet.

B.2 The canonical surface defect $r = 1$

Let us consider the case of the canonical surface defect, i.e. $r = 1$. The full defect index can be simplified to\(^{13}\)

$$I_{S_1}(p, q, t, a_1) = \frac{1}{\theta_p(t)\theta_p(a_1^2 t)} \frac{1}{\theta_p(p)\theta_p(a_1^2 p t)} \frac{1}{\theta_p(q)\theta_p(a_1^2 q t)} \frac{1}{\theta_p(1)\theta_p(a_1^2 t^2 q)} = 2 \Gamma(a_1^2 t \frac{1}{2}) \Gamma(a_1^{-2} t \frac{1}{2}) \quad (B.6)$$

Let us consider the Macdonald limit (4.18) $p \to 0$ of the canonical surface defect in a free hypermultiplet theory:

$$I_{S_1}(q, t, a_1) = \frac{1 - t q^{-1}}{a_1^2 t \frac{1}{2} q^{-1} ; q} \quad (B.7)$$

The Schur index is a further limit of the Macdonald index by setting $t = q$, which gives $0$ we already saw in (4.4).

For a general 4d SCFT with discrete spectrum, the Macdonald index admits an expansion in $q$ while keeping $t/q$ fixed. If we perform such an expansion for (B.7), we find that at each power of $q$ there are infinitely many terms coming from the two $q$-Pochhammer symbols. This is consistent with the infinite degeneracy at each level in the twisted module of the corresponding chiral algebra.

B.3 The vortex defect with $r = 2$

More generally, the contribution from the \{m_1, m_2\} pole to the Macdonald index is

$$2 I_V A_{m_1, m_2} \quad (B.8)$$

The Schur index of the $r = 2$ vortex defect $S_2$ is then

$$I_{S_2}(q, t, a_1) = 2 I_V R_{0,2}^{-1} (A_{2,0} + A_{1,1} + A_{0,2}) \quad (B.9)$$

\(^{13}\)If we directly take the Schur limit $t = q$, the surface defect index is not analytic in $q$ and depends on $p$. In general we define the Schur limit in the presence of surface defects by first taking $p \to 0$ and then $t \to q$. 

---

140
The rightmost factor \( \frac{1}{(a^2q^2; q)_\infty (a^{-2}q^2; q)_\infty} \) is the Macdonald index for a free hypermultiplet. In the Schur limit \( t = q \), we recover, up to an overall sign, the Schur index of the free hypermultiplet without defects,

\[
- \frac{1}{(a^2q^2; q)_\infty (a^{-2}q^2; q)_\infty}.
\]

(B.10)

We conclude that even though the \( r = 2 \) vortex defect \( S_2 \) shares the same Schur index and the trivial defect in the free hypermultiplets, they are in fact physically distinct and can be already distinguished by the more refined Macdonald index.
