Zinc oxide nanoparticles
Ultraviolet radiation
Aqueous solutions

ABSTRACT

The aim of this data was to evaluate the efficiency of zinc oxide nanoparticles plus ultraviolet radiation (UV/ZnO) technology to remove Acid – 32 – Cyanine 5R. The effect of optimal parameters including initial pH (5,10), contact time (2–20 min), initial dye concentration (0.5–2 mg/L), and zinc oxide dosage (0.1 and 0.2 g/L) was investigated. The data showed that under alkaline conditions (pH = 10) and 0.2 g/L of ZnO nanoparticles, the maximum dye removal efficiency was observed under UV/ZnO process conditions. Furthermore, with the increase in Acid – 32 – Cyanine 5R dye concentration, the removal efficiency of the dye diminished, while with prolongation of the radiation time, the removal efficiency increased. In the presence of ultraviolet radiation, there is a need to longer time and higher radiation intensity for complete removal of the dye. However, in the presence of ZnO nanoparticles alone, around 5–10% of the dye is removed. The highest removal efficiency of Acid – 32 dye was through radiation by ultraviolet lamp 150 W at an initial dye concentration of 1 mg/L, in pH 5 and 10, respectively, at 98.5% and 99% respectively. On
on the other hand, through hybrid use of UV/ZnO, within a shorter time, complete removal (100%) is achieved. Generally, use of UV/ZnO process can be utilized as a suitable method for dye wastewaters treatment.

### Value of the data

- The obtained data present a high efficiency method for removed Acid – 32 – Cyanine 5R dye from the wastewater of textile industries.
- The information of the data includes the methods of zinc oxide nanoparticles plus ultraviolet radiation (UV/ZnO), use of zinc oxide nanoparticles alone (ZnO), and ultraviolet radiation process (UV) in removing Acid – 32 – Cyanine 5R dye from aqueous solutions.
- The research data indicate that the photocatalytic process with the help of ZnO nanoparticles under ultraviolet radiation (UV/ZnO) can completely remove Acid – 32 – Cyanine 5R acidic dye within a shorter time.
- The data will be useful for removing Acid – 32 – Cyanine 5R dye from water and wastewater.
1. Data

The efﬁciency of Acid – 32 dye removal through radiation with the help of ultraviolet lamp 150 W at different pH has been shown in Tables 1 and 2. Figs. 1 and 2 demonstrate the Acid – 32 dye removal efﬁciency using ZnO nanoparticles alone within the contact time of 20 min with ZnO dosage of 0.1 and 0.2 g/L. The Acid – 32 dye removal efﬁciency using the nanophotocatalytic method of UV/ZnO at different pH (5 and 10) and ZnO dosage (0.1 and 0.2 g/L) can be observed. Fig. 3 displays the schematic of the photocatalyst reactor. The qualitative properties of the dyeing wastewater studied here can be seen in Table 7. Fig. 4 reveals Acid – 32 – Cyanine 5 dye removal efﬁciency from real wastewater (dyeing) using UV/ZnO nanophotocatalytic method under optimal process conditions (Tables 3–6).

2. Designing the experiments, materials and methods

2.1. Materials

All of the chemical used in the data such as Acid – 32 – Cyanine 5R dye, ZnO nanoparticles (purity degree = 99.8%), ultraviolet lamp (150 W), HCl and NaOH were all analytical grade. Stock solution 50 mg/L of Acid – 32 – Cyanine 5R dye was used to prepare the dye samples with the concentrations of interest. ZnO nanoparticles were prepared from NanoPars Spadana Co.[1,2]. Then, using a furnace at 400 °C, it was activated for 30 min and utilized to perform the dye removal experiments.

The pH of the solutions was measured using a pH meter E 250. All experiments related to COD-BOD5–pH variables and TSS were performed according to the standard edition of the 22st ed [3]. The color concentration was determined using the Perkin–Elmer lambada 25-UV/Vis and the true color was measured in ADMI (American Dye Manufactures Institute) units at 400–700 nm wavelengths.

2.2. Designing the experiments

All of the dye removal experiments were performed in a glass container with a volume of 2 L and useful volume of 1 L as batch using ZnO nanoparticles as mixed with a dye-containing synthetic solution. After adding the ZnO nanoparticles, the intended solutions were placed on a magnetic stirrer for 20 min in darkness for mixing to occur (IkA-Werke) [1,2,4–6]. After that, the intended solution was transferred to a photocatalytic reactor. Inside the reactor, medium-pressure UV lamp (150 W) was used as the radiation source (Fig. 3). To cool the lamp down and keep the temperature uniform throughout the experiments, a 2-L beaker was placed inside a glass container containing cool water and thermometer, so that the temperature would remain constant around 24 °C across all of the experiments. The pH of the samples of interest was adjusted using HCl 0.1 M and NaOH 0.1 M.

solutions by a pH meter (pH-meter E 250) [7–10]. The effect of the optimization parameters including the initial pH (5 and 10), dose of ZnO nanoparticles (0.1 and 0.2 mg/L), contact time (2–20 min), and initial dye concentration (0.5–2 mg/L) was examined on Acid–32–Cyanine 5R dye removal. The Acid–32–Cyanine 5R dye removal efficiency was investigated under the processes of 1) nanophotocatalytic UV/ZnO, 2) radiation alone (UV), and 3) ZnO nanoparticles alone. At the end of the

experiments, ZnO nanoparticles were separated from the solution through centrifugation (Hettich – Universal) at 10,000 rpm for 10 min in two stages. After that, the residual concentration of Acid – 32 – Cyanine 5R dye was determined by a spectrophotometer device (Perkin–Elmer Lambada 25 – UV/vis) at the wavelength of 400–700 nm [1–6].

2.3. Investigating the Acid – 32 – Cyanine 5R dye removal efficiency in real dyeing wastewater samples

To evaluate the Acid – 32 – Cyanine 5R dye removal efficiency, samples were taken from the output wastewater of a dyeing workshop. They were then kept at certain time intervals under optimal
2.4. Data analysis

The Acid – 32 – Cyanine 5R dye removal efficiency was determined by the following equation:

$$RE = \left(\frac{C_i - C_f}{C_i}\right) \times 100$$

In this equation, $C_i$ represents the initial concentration of the dye in the suspension (mg/L) and $C_f$ shows the final concentration of the dye in the suspension (mg/L) [1,2].
