The cable equation describes the voltage in a straight cylindrical cable, this model has been employed to model electrical potential in dendrites and axons. However, sometimes this equation might give incorrect predictions for some realistic geometries, in particular when the radius of the cable changes significantly. Cables with a non constant radius are important for some phenomena, for example discrete swellings along the axons appear in neurodegenerative diseases such as Alzheimer, Parkinson, HIV-associated dementia and Multiple Sclerosis. In this paper, using the Frenet-Serret frame, we propose a generalized cable equation for a general cable geometry. This generalized equation depends on geometric quantities such as the curvature and torsion of the cable. We show that when the cable has a constant circular cross-section, the first fundamental form of the cable can be simplified and the generalized cable equation depends on neither the curvature nor the torsion of the cable. Additionally, we find an exact solution for an ideal cable which has a particular variable circular cross-section and zero curvature. In addition, we study different cables with swelling and provide their numerical solutions. The numerical solutions show that when the cross-section of the cable has abrupt changes, its voltage is smaller than the voltage in the cylindrical cable. Furthermore, these numerical solutions show that the voltage can be affected by geometrical inhomogeneities on the cable.

I. INTRODUCTION

Understanding how the brain works is relevant for different medical and technological applications. In this respect it is central to know the electrical brain activity. The basic unit in the brain is given by neurons, which transmit electrical signals through axons and receive electrical signals through dendrites. Thus, it is important understand the electrical behaviour of dendrites and axons. Axons and dendrites can be described as cables with special properties. It is worth to mentioning that the first model for an electrical cable was proposed by Lord Kelvin in the telegraph problem context. Inspired in the Lord Kelvin’s work, different authors have proposed models to describe dendrites and axons. For example, Rall proposed that a dendrite can be taken as a cable with a circular cross-section and constant diameter $d_0$ where the voltage $V(x,t)$ satisfies the cable equation

$$c_M \frac{\partial V(x,t)}{\partial t} = \frac{d_0}{4r_L} \frac{\partial^2 V(x,t)}{\partial x^2} - i_{ion},$$

here $c_M$ denotes the specific membrane capacitance, $r_L$ denotes the longitudinal resistance and $i_{ion}$ is the ionic current per unit area into and out of the cable. In the passive cable case, namely when $i_{ion} = V/r_M$, with $r_M$ the specific membrane resistance, the equation (1) is exactly solved [3,5].

The cable equation has been useful to explain different phenomena in dendrites and axons [3-5]. However, there are axons and dendrites with different geometry, in particular axons and dendrites with a variable radius, and the cable equation only describes cylindrical cables with a constant radius. Furthermore, there are phenomena where the geometry of the axons and dendrites is relevant. For example, axons with a non constant radius are hallmark features of some neurodegenerative diseases. Actually, discrete swellings along the axons appear in neurodegenerative diseases such as Alzheimer, Parkinson, HIV-associated dementia and Multiple Sclerosis [6-8]. Remarkably, in an extreme cases, the electrical signal is deleted in the swelling of the axon. Additionally, theoretical and experimental studies show that dendritic geometry determines the efficacy of voltage propagation [9,10]. Another example of dendrites with non trivial geometry is given by spiny dendrites which exhibit anomalous diffusion [11]. In addition,
dendrites with varying diameter are found in synaptic contacts, retina amacrine cells, the cerebellar dentate nucleus and the lateral vestibular nucleus, as well as cortical pyramidal and olfactory bulb cells [12–14]. Furthermore, recent theoretical studies emphasize the spatial variability of dendritic calcium dynamics due to local changes in a dendrite diameter [15]. For these reasons, it is important to study cables with general geometry. Some extensions of the cable model can be seen in [16–18].

In this paper, using the Frenet-Serret frame, we propose a cable with general geometry and construct a generalized cable equation for the voltage in it. This generalized equation depends on geometric quantities as curvature and torsion of the cable. For the general case, this new equation is very complicated. Nevertheless, we show that when the cable has a constant circular cross-section the generalized cable equation depends on neither the curvature nor the torsion of the cable. In fact, in this last case the new cable equation is equivalent to the cable equation for a straight cylindrical cable. Moreover, we find an exact solution for an ideal cable with a particular variable circular cross-section and zero curvature. In this case, we show that when radius increases the voltage decreases. Inspired in this ideal case, we rewrite the generalized cable equation as a diffusion equation with a source term. In this diffusion equation the source term and the diffusion coefficient are generated by the cable geometry. In addition, we provide numerical solutions to different cable with swelling. The numerical solutions show that the voltage can be affected by geometrical inhomogeneities on the cable. These numerical results are consistent with the behaviour of the voltage in focal axonal swellings [6].

This paper is organized as follows: in the section II we propose a cable with a general geometry; in the section III we propose a generalized cable equation; in the section IV we study a cable with a circular cross-section; in the section V we study a particular cable with a variable radius; in the section VI we study some general properties of the generalized cable equation; in the section VII we provide numerical solutions to the cable equation. Finally, in the section VIII a summary is given.

II. CABLE GEOMETRY

It is well known that a three dimensional curve \( \vec{\gamma} \) can be reparametrized with different parameters and its geometric properties are invariant under reparametrizations. For example, the arc length of the curve \( \vec{\gamma} \) is given by

\[
s = \int_0^x \sqrt{\frac{d\gamma^2(\zeta)}{d\zeta} + \frac{d\gamma^2(\zeta)}{d\zeta} d\zeta},
\]

(2)

which is invariant under reparametrization on \( \zeta \). Notably, the arc length parameter \( [2] \) is a friendly parameter to study the geometric properties of a tridimensional curve. For instance, using the arc length parameter \( [2] \) we can construct the vectors of the Frenet-Serret frame \( [19] \)

\[
\frac{d\vec{\gamma}(s)}{ds} = \hat{T}, \quad \vec{N} = \frac{d\vec{T}}{d\vec{F}} \times \hat{T}, \quad \vec{B} = \hat{T} \times \vec{N},
\]

(3)

where \( \hat{T} \) is the unit vector tangent, \( \vec{N} \) is the normal unit vector and \( \vec{B} \) is the binormal unit vector to the curve.

Furthermore, using the arc length and the Frenet-Serret frame, the Frenet-Serret formulas can be obtained as follow \( [19] \)

\[
\frac{d\hat{T}}{ds} = \kappa \vec{N}, \quad \frac{d\vec{N}}{ds} = -\kappa \hat{T} + \tau \vec{B}, \quad \frac{d\vec{B}}{ds} = -\tau \vec{N},
\]

(4)

where \( \kappa, \tau \) are the curvature and torsion of the curve \( \vec{\gamma} \), respectively.

We can employ the Frenet-Serret frame to construct a cable model. Actually, we can propose a general cable as the region bounded by the following surface

\[
\vec{\Sigma}(\theta, s) = \vec{\gamma}(s) + f_1(\theta, s)\vec{N}(s) + f_2(\theta, s)\vec{B}(s),
\]

(5)

here \( \theta \) is an angular variable. Notice that employing the angular coordinate \( \theta \), the functions \( f_1(\theta, s), f_2(\theta, s) \) and the vectors \( \vec{N}(s), \vec{B}(s) \) we are constructing the cable over the curve \( \vec{\gamma}(s) \). For example, a cable with a circular cross-section with radius \( R(s) \) can be parameterized with the functions

\[
f_1(\theta, s) = R(s) \cos \theta, \quad f_2(\theta, s) = R(s) \sin \theta.
\]

(6)

In the figure we can see a representation of the surface \( \vec{\Sigma} \).

Some geometric quantities as the area of a surface can be written in terms of the first fundamental form, which is constructed with the inner product on the tangent space of a surface \( [19] \). In the case of the surface \( \vec{\Sigma} \) we have

\[
g = \begin{pmatrix} E & F \\ F & G \end{pmatrix},
\]

(7)
where the first form coefficients are
\[ E = \left| \frac{\partial \Sigma(\theta, s)}{\partial s} \right|^2 = (1 - \kappa f_1)^2 + \left( \frac{\partial f_1}{\partial s} - \tau f_2 \right)^2 \]
\[ + \left( \frac{\partial f_2}{\partial s} + \tau f_1 \right)^2, \quad (8) \]
\[ G = \left| \frac{\partial \Sigma(\theta, s)}{\partial \theta} \right|^2 = \left( \frac{\partial f_1}{\partial \theta} \right)^2 + \left( \frac{\partial f_2}{\partial \theta} \right)^2, \quad (9) \]
\[ F = \frac{\partial \Sigma(\theta, s)}{\partial s} \cdot \frac{\partial \Sigma(s, \theta)}{\partial \theta} = \left( \frac{\partial f_1}{\partial s} - \tau f_2 \right) \frac{\partial f_1}{\partial \theta} \]
\[ + \left( \frac{\partial f_2}{\partial s} + \tau f_1 \right) \frac{\partial f_2}{\partial \theta}. \quad (10) \]

Using the first fundamental form, an area element of the cable surface \((5)\) can be written as
\[ \Delta A = \left( \int_{0}^{2\pi} d\theta \sqrt{\det g(\theta, s)} \right) \Delta s, \quad (11) \]
where
\[ \det g(\theta, s) = \left[ \left( \frac{\partial f_1}{\partial s} \frac{\partial f_2}{\partial \theta} - \frac{\partial f_2}{\partial s} \frac{\partial f_1}{\partial \theta} \right) - \frac{\tau}{2} \frac{\partial}{\partial \theta} (\dot{f}_1^2 + \dot{f}_2^2) \right]^2 \]
\[ + (1 - \kappa f_1)^2 \left[ \left( \frac{\partial f_1}{\partial \theta} \right)^2 + \left( \frac{\partial f_2}{\partial \theta} \right)^2 \right]. \quad (12) \]

Notice, that the area element \((11)\) depends on the curvature \(\kappa\) and the torsion \(\tau\) of the curve \(\gamma\).

In particular, when the cable has a circular cross-section with radius \(R(s)\), namely when the cable is reparametrized with the functions \((6)\), the area element of cable surface \((5)\) is given by
\[ \Delta A = R(s) \Delta s \]
\[ \times \int_{0}^{2\pi} d\theta \sqrt{(1 - \kappa(s) R(s) \cos \theta)^2 + \left( \frac{dR(s)}{ds} \right)^2}, \quad (13) \]
while the cable cross-section area is
\[ a(s) = \pi R^2(s). \quad (14) \]

We can see that the area element \((13)\) does not depend on the torsion \(\tau\) of the curve \(\gamma\).

Now, the Gaussian curvature characterizes the curvature of a surface \([19]\). In particular, if the cable \((5)\) has a circular cross-section with a constant radius \(R_0\), the Gaussian curvature of the surface of this cable is given by
\[ K = -\frac{\kappa(s) \cos \theta}{R_0 (1 - \kappa(s) R_0 \cos \theta)}, \quad (15) \]
Notice that this quantity is singular when \(\kappa(s) R_0 \geq 1\). Because of the surfaces of the axons or dendrites reported are smooth surfaces, we can suppose that the Gaussian curvature of the surfaces of axons or dendrites does not have singularities. Notice that this hypothesis implies the inequality \(\kappa(s) R_0 < 1\). In addition, let us remember that the curvature \(\kappa(s)\) at a point \(P\) of the curve \(\gamma(s)\) is defined as the inverse of the radius of the osculating circle at \(P\), see \([20]\). Then, if at this point \(P\) the cable radius is \(R(s)\), the radius of the osculating circle must be larger than \(R(s)\). Thus, at the point \(P\) the curvature \(\kappa(s)\) must be smaller than \(R^{-1}(s)\) and the following inequality
\[ \kappa(s)R(s) < 1 \quad (16) \]
the equation (22) can be written as
\[ c = \text{constant} \]
where it depends on neither the torsion \( \tau \) nor the curvature \( \kappa \).

In the next section we will propose a cable equation when a cable is described by (5).

### III. CABLE EQUATION

In order to propose a cable equation to a cable with the geometry given by the equation (5), we break the curve \( \gamma(s) \) into \( n \) pieces. Each piece has a surface area \( \Delta A_i \) and a cross sectional area \( a_i \) \( (i = 0, 1, 2, \ldots n) \).

Now, we consider a current flow \( I_{\text{long}}(s,t) \) along the cable. Then, if \( V(s,t) \) is the membrane potential and \( R_L \) is the resistance of the cable, from the Ohm’s law we have
\[ V(s + \Delta s, t) - V(s, t) = -I_{\text{long}}(s,t)R_L. \tag{18} \]
In addition, due to the resistance to a cable with a cross-sectional area \( a(s) \) is \[ R_L = \frac{r_L \Delta s}{a(s)}, \tag{19} \]
where \( r_L \) is the specific intracellular resistivity, from the Ohm’s law we obtain
\[ I_{\text{long}} = -\frac{a(s)}{r_L} \left( \frac{V(s + \Delta s, t) - V(s, t)}{\Delta s} \right) \approx -\frac{a(s)}{r_L} \frac{\partial V(s, t)}{\partial s}. \tag{20} \]
Furthermore, if \( C_M \) is the membrane capacitance, we get
\[ Q_{\text{cap}} = VC_M, \tag{21} \]
which implies
\[ I_{\text{cap}} = \frac{dQ}{dt} = C_M \frac{\partial V(s, t)}{\partial t}. \tag{22} \]
Observe that the capacitance for the cable surface can be taken as
\[ C_M = \Delta A(s)c_M, \tag{23} \]
where \( c_M \) is the specific membrane capacitance. Thus, the equation (22) can be written as
\[ I_{\text{cap}} = \Delta A(s)c_M \frac{\partial V(s, t)}{\partial t}. \tag{24} \]
Moreover, the total ionic current that flows across the membrane is
\[ I_{\text{ion}} = (\Delta A)i_{\text{ion}}, \tag{25} \]
where \( i_{\text{ion}} \) is the current per unit area into and out of the cable.

Hence, the change in cable current is given by
\[ I_{\text{cap}} + I_{\text{ion}} = -I_{\text{long}}(s + \Delta s, t) + I_{\text{long}}(s, t), \tag{26} \]
which implies
\[ \Delta A(s)c_M \frac{\partial V(s, t)}{\partial t} + (\Delta A)i_{\text{ion}} \approx \frac{a(s + \Delta s)}{r_L} \frac{\partial V(s + \Delta s, t)}{\partial s} - \frac{a(s)}{r_L} \frac{\partial V(s, t)}{\partial s}. \]

Then, if \( \vec{\gamma} \) \((s,t) \) is the membrane potential, we get
\[ \partial V(s, t) + \frac{i_{\text{ion}}}{C_M} \approx \frac{1}{r_L C_M \int_0^{\pi / 2} du \sqrt{g(u,s)}} \frac{dV(s + \Delta s, t)}{ds} - \frac{a(s)}{r_L} \frac{\partial V(s, t)}{\partial s}. \tag{27} \]

Thus, at the limit \( \Delta s \to 0 \) we arrive to
\[ \frac{\partial V(s, t)}{\partial t} = \frac{1}{r_L C_M \int_0^{\pi / 2} du \sqrt{g(u,s)}} \frac{dV(s + \Delta s, t)}{ds} - \frac{a(s)}{r_L} \frac{\partial V(s, t)}{\partial s}. \tag{28} \]
This equation is the cable equation when the cable geometry is given by (5) and it depends on geometric quantities as the curvature \( \kappa \) and torsion \( \tau \) of the cable.

In the general case, \( i_{\text{ion}} \) depends on the voltage and the equation (28) is a non linear differential equation. However, in the passive cable model we can take
\[ i_{\text{ion}} = \frac{V(s, t)}{r_M}, \tag{29} \]
Therefore, the cable equation for the passive cable model with the geometry given by (5) is
\[ \frac{\partial V(s, t)}{\partial t} = \frac{1}{r_L C_M \int_0^{\pi / 2} du \sqrt{g(u,s)}} \frac{dV(s + \Delta s, t)}{ds} - \frac{V(s, t)}{r_M C_M}. \tag{30} \]
For an infinite cable, the voltage has to satisfy the Dirichlet boundary condition, while for a finite cable the voltage has to satisfy the Neumann boundary condition (3).

In the next section we will study some exactly solvable cases of the equation (30).
IV. CIRCULAR CROSS-SECTION

A cable with a deformed circular cross-section where the radius depends on the angle θ, namely \( R = R(\theta, s) \), can be modeled with the surface \([5]\) where
\[
f_1(\theta, s) = R(\theta, s) \cos \theta, \quad f_2(\theta, s) = R(\theta, s) \sin \theta.
\] (31)

In this case the cross-section area is given by
\[
a(s) = \frac{1}{2} \int_0^{2\pi} R^2(\theta, s) d\theta,
\] (32)
in addition we obtain
\[
\sqrt{\det g(\theta, s)} = \left[ R^2(\theta, s) \left( \frac{\partial R(\theta, s)}{\partial s} - \tau \frac{\partial R(\theta, s)}{\partial \theta} \right)^2 + (1 - \kappa s)R(s) \cos \theta \right]^{\frac{1}{2}}.
\] (33)

For this general cable geometry, to find solutions of the cable equation (30) is a difficult task. However, for some cases this equation can be simplified. For instance, for the straight cylindrical cable with the same radius. Furthermore, in this case voltage is not different from the voltage for the straight cylindrical cable with the same radius.

Thus, if a cable has a constant radius \( R_0 \), the voltage in cable depends on neither the curvature nor the torsion. Furthermore, in this case voltage is not different from the voltage for the straight cylindrical cable with the same radius.

The figure \([2]\) shows the cable equation solution for a cylindrical cable.

In the following sections we will study cables with a variable radius.

V. AN EXACT SOLUTION WITH A VARIABLE RADIUS

Cables with a no constant radius are important for different reasons. For example, discrete swellings along the axons appear in neurodegenerative diseases such as Alzheimer, Parkinson, HIV-associated dementia and Multiple Sclerosis. In particular, in Parkinson disease there are reported axons with a diameter of approximately 1\(\mu\)m with a swelling with diameter of approximately 5\(\mu\)m, see \([22]\). In addition, in Multiple Sclerosis there are reported axons with a diameter of approximately 4\(\mu\)m with a swelling with a diameter of approximately 60\(\mu\)m, see \([23]\). In Alzheimer disease there are reported axons with a diameter of approximately 1.5\(\mu\)m with a swelling train, where the swelling diameter varies between 4\(\mu\)m and 10\(\mu\)m, see \([24-26]\). For HIV-associated dementia, there are reported axons with a diameter of approximately 6\(\mu\)m and swellings with a diameter of approximately 43\(\mu\)m, see \([27, 31]\).

Other sizes of the axonal swellings can be seen in \([7, 24]\).

When the radius \( R(\theta, s) \) is not a constant, the equation (34) is very complicated. However, some ideal cases can help us to understand the general case. In this section, we study an ideal case which does not represent a realistic axon or dendrite, but it will help us to understand the generalized cable equation (30).

For an infinite cable, the solution of the equation (35) is
\[
V(s, t) = V_0 l_0 \sqrt{\frac{r_{LM}}{2\pi R_0 t}} e^{-\frac{r_{LM}^2}{2r_0^2 t}} e^{-\frac{r_0^2}{4R_0^2 t}}.
\] (36)

where \( V_0 \) is a constant with voltage dimensions and \( l_0 \) is a constant with length dimensions. Notice that in this case the initial condition
\[
V(s, 0) = V_0 l_0 \delta(s)
\] (37)
is satisfied, where \( \delta(s) \) is the Dirac delta function. Moreover, using the lab frame coordinate \( x \) and the equation (2), the voltage (36) can be written as
\[
V(x, t) = V_0 l_0 \sqrt{\frac{r_{LM}}{2\pi R_0 t}} e^{-\frac{r_{LM}^2}{2r_0^2 t}} e^{-\frac{r_0^2}{4R_0^2 t}}.
\]

Thus, if a cable has a constant radius \( R_0 \), the voltage in cable depends on neither the curvature nor the torsion. Furthermore, in this case voltage is not different from the voltage for the straight cylindrical cable with the same radius.

The figure \([2]\) shows the cable equation solution for a cylindrical cable.

In the following sections we will study cables with a variable radius.
FIG. 2. Voltage for the cylindric cable. Parameter values used for simulations correspond to realistic dendritic parameters as in [14]: \( c_M = 1\, \text{mF/cm}^2 \), \( r_M = 3000\, \Omega \cdot \text{cm}^2 \), \( r_L = 100\, \Omega \cdot \text{cm} \), \( R_0 = 10^{-4} \, \text{cm} \). The initial condition is given by (47).

The initial condition is given by (47).

The equation (34) becomes
\[
\frac{\partial V(s,t)}{\partial t} = \frac{R_0^2}{2r_Lc_M} \frac{\partial^2 V(s,t)}{\partial s^2} + \frac{1}{r_Lc_M} \sinh \left( \frac{s}{R_0} \right) \frac{\partial V(s,t)}{\partial s}
- \frac{V(s,t)}{r_Mc_M},
\]
which is solved by the voltage
\[
V(s,t) = V_0^2 \frac{a(s)}{R(s)} \sqrt{\frac{r_Lc_M}{2\pi R_0 t}} e^{-\frac{r_L^2 s^2}{2r_M^2}} e^{-t \left( \frac{1}{r_M^2} + \frac{1}{r_L^2} \right)}, \tag{39}
\]
Notice that when the radius (38) increases the voltage (39) decreases.

In the figure 3 we can see the voltage (39).

VI. GENERAL PROPERTIES

Studying the ideal cable (38) we learned that when the time increases the voltage (39) decreases. In addition, this voltage depends on \( R^-(s) \), namely this voltage depends on \( (\sqrt{a(s)})^{-1} \), where \( a(s) \) is the cable cross-section area. Then, inspired in the ideal case (39), in order to study the equation (30), we propose the following voltage
\[
V(s,t) = \frac{\Psi(s,t)}{\sqrt{a(s)}}. \tag{40}
\]
Thus, the equation (30) implies
\[
\frac{\partial \Psi(s,t)}{\partial t} = D(s) \frac{\partial^2 \Psi(s,t)}{\partial s^2} + \rho(s,t) \tag{41}
\]
where
\[
D(s) = \frac{\sqrt{a(s)}}{r_Lc_M \int_0^{2\pi} d\theta \sqrt{\text{det} g(\theta,s)}} \left( \frac{1}{4} \frac{da(s)}{ds} \right)^2 \frac{1}{a^2},
\]
\[
\rho(s,t) = \frac{\sqrt{a(s)}}{r_Lc_M \int_0^{2\pi} d\theta \sqrt{\text{det} g(\theta,s)}} \left( \frac{1}{4} \frac{da(s)}{ds} \right)^2 \frac{1}{a^2}
- \frac{1}{2a^2(s)} \frac{d^2 a(s)}{ds^2} - \frac{r_L \int_0^{2\pi} d\theta \sqrt{\text{det} g(\theta,s)}}{r_M \sqrt{a(s)}} \Psi(s,t).
\]
Notice that the equation (41) can be interpreted as a diffusion equation with a source, in this equation the coefficient diffusion and the source term are generated by the cable geometry.

Now, we can see that if we take
\[
\Psi(s,t) = e^{-Et} \psi(s), \tag{42}
\]
where $E$ is a constant with (time)$^{-1}$ dimensions, the equation (41) becomes

$$-\frac{\partial^2 \psi(s)}{\partial s^2} + U(s)\psi(s) = 0,$$  (43)

here

$$U(s) = -\left(\frac{d\alpha(s)}{ds}\right)^2 + \frac{1}{4a^2(s)} \frac{d^2 a(s)}{ds^2} + \frac{r_L}{r_M c_M} \left( E - \frac{1}{r_M c_M} \right) \int_0^{2\pi} d\theta \sqrt{\text{det} g(\theta, s)}.$$  (44)

If $E = 0$ the equation (43) is the equilibrium description of the diffusion equation (41). Moreover, in some cases the Fokker-Planck equation and the diffusion equation can be rewritten as a Schrödinger equation (43). In this respect, notice that the equation (43) can be seen as a Schrödinger equation where $U(s)$ is an effective potential, which is generated by the cable geometry.

In particular, when the radius of the cable is a constant the effective potential is the constant

$$U(s) = U_0 = -\frac{2r_L c_M}{R_0} \left( E - \frac{1}{r_M c_M} \right).$$  (45)

When the radius is not a constant, the function $\psi(s)$ is affected by the effective potential (44). For example, if the cable has a circular cross-section with radius $R(s)$, the effective potential is

$$U(s) = \frac{1}{R(s)} \left( \frac{1}{2} \frac{d^2 R(s)}{ds^2} - \left( E - \frac{1}{r_M c_M} \right) \frac{r_L c_M}{\pi} \times \int_0^{2\pi} d\theta \sqrt{(1 - \kappa(s) R(s) \cos \theta)^2 + \left( \frac{dR(s)}{ds} \right)^2} \right).$$  (46)

From this last equation we can see that if the derivatives of the radius $R(s)$ are small quantities, then the radius can be approximated by a constant and the effective potential can be approximated by a constant too. In this case, the voltage in the cable is similar to the cylindrical cable. Moreover, observe that the condition (46) implies that $(1 - \kappa(s) R(s) \cos \theta)^2$ is a small quantity. Then, when $(\frac{dR}{ds})^2$ is a large quantity and $(1 - \kappa(s) R(s) \cos \theta)^2 \ll (\frac{dR}{ds})^2$, the effective potential depends on neither the curvature nor the torsion. Thus, in this last case, cables with similar swelling have similar voltage.

When the cable has a deformed circular cross-section with radius $R = R(\theta, s)$, we should introduce the equations (32) and (33) in the effective potential (44). In this case we can see that the effective potential is affected by derivatives of the radius respect to the angle $\theta$. Then, geometrical inhomogeneities on a cable might affect the voltage.

In the next section we will provide numerical solution for cable with different geometries.

VII. NUMERICAL SOLUTIONS

In this section the differential equation (30) is solved by using the second order finite differences method for both spatial coordinate and temporal evolution. The choice of mesh size was made with the usual procedure. First we begin with 1024 points along the s-axis and 50 points in the time. The meshes for s-direction and for the time were refined several times. We stop when no differences in solutions are obtained in two successive refinements. The number of spatial and temporal points used in the simulation is shown in Table I.

The system is solved using the Gauss-Seidel iterative
In the figure 4(c) we plot the maximum voltage as a function of $\alpha_3$ for two different values of $\alpha_4$. We can see that the voltage to cable with a realistic geometry is not different from the voltage for a cylindrical cable.

### B. Cable with Gaussian swelling

Now, we study a cable with the radius

$$R(s) = R_0 \left( 1 + \alpha_3 e^{-\alpha_5(s-\alpha_6)^2} \right).$$

In the figure 5(a) can see a cable with this geometry. The numerical solution to the voltage can be seen in the figure 5(b). In this figure we can see that the voltage decreases faster than the voltage to the cylindrical cable. Notice that for this geometry when the height of the swelling increases the voltage of the cable decreases. In fact, for a big $\alpha_3$ parameter the voltage can be blocked.

### C. Cable with Gaussian swellings

In this section we study the cable with the following radius

$$R(s) = R_0 \left( 1 + \alpha_3 e^{-\alpha_5s^2} + \alpha_3 e^{-\alpha_5(s-\alpha_6)^2} + \alpha_3 e^{-\alpha_5(s-2\alpha_6)^2} + \alpha_3 e^{-\alpha_5(s-3\alpha_6)^2} \right).$$

A cable with this geometry can be seen in the figure 6(a) and the numerical solution to the voltage in this cable can be seen in the figure 6(b). In this case we can see that the voltage decreases faster than the voltage to the cylindrical cable. Moreover, notice that for this geometry when the height of the swelling increases the voltage of the cable decreases. Observe that the voltage in this cable decreases more than the voltage in the cable with radius 51. Actually, if $\alpha_3$ is a big parameter the voltage can be blocked.

### D. Amorphous swelling

In the literature there are reported axons with amorphous swelling [6]. For an amorphous cable we can propose the following radius

$$R(\theta, s) = R_0 \left( 1 + \alpha_3 e^{-\alpha_5(s-\alpha_6)^2} + \alpha_7 \sin \theta \cos \alpha_8 s \right).$$

A cable with this geometry can be seen in the figure 7(a) and the numerical solution for the voltage in this...
FIG. 4. (a) Cable with geometry \([48]\). (b) Cable with geometry \([50]\). (c) Maximum voltage for a cable with radius \([50]\) at time \(t = 1000\text{sec}\) vs the parameter \(\alpha_3\). The voltage changes only if \(\alpha_3 > 50\), a values for non-realistic cable geometries with swellings. Parameter values used for simulations correspond to realistic dendritic parameters as in \([14]\): \(c_M = 1\text{mF/cm}^2\), \(r_M = 3000\Omega \cdot \text{cm}^2\), \(r_L = 100\Omega \cdot \text{cm}\), \(R_0 = 10^{-4}\text{cm}\). The initial condition is given by \([47]\).

cable can be seen in the figure \([7]\)(b), (c), (d). In this case we can see that the voltage decreases faster than the voltage to the cylindrical cable. In addition, observe that the voltage in this cable decreases more than the voltage in the cable with radius \([51]\). Thus, geometric inhomogeneities in a cable can change its voltage in it.

Axons with swellings are hallmark features of some neurodegenerative diseases such as Alzheimer, Parkinson, HIV-associated dementia and Multiple Sclerosis \([6\text{–}8]\). The numerical results of this section indicate us when the cable geometry is important to the voltage propagation. These results show that when the derivatives of the cable radius are slowly changing functions, namely when \(\left(\frac{dR}{ds}\right)^2 \ll \left(1 - \kappa(s)R(s)\cos\theta\right)^2\) and \(\frac{d^2R(s)}{ds^2} \ll \frac{c_M}{r_M}\), the voltage is similar to voltage in a straight cylindrical cable. However, when these derivatives change significantly the voltage cable is reduced and, in a extreme case, it can be blocked. Moreover, these numerical results show that geometric inhomogeneities in a cable can affect the voltage.

FIG. 5. (a) Cable with geometry \((51)\). (b) Voltage for the cable with a gaussian swelling, radius \((51)\). (c) Voltage vs \(t\) in \(s = 0\) with different values for \(\alpha_3\). (d) Voltage vs \(s\) at time \(t = 1000\) sec for different values of \(\alpha_3\). Parameter values used for simulations correspond to realistic dendritic parameters as in \([14]\): \(c_M = 1\) \(mF/cm^2\), \(r_M = 3000\Omega \cdot cm^2\), \(r_L = 100\Omega \cdot cm\), \(R_0 = 10^{-4}\) cm. The initial condition is given by \((47)\).

VIII. SUMMARY

In this paper, using the Frenet-Serret frame, we proposed a cable with general geometry and construct a generalized cable equation to the voltage in it. This generalized equation depends on geometric quantities as curvature and torsion of the cable. For the general case, this equation is very complicated to obtain exact solutions. However, when the cable has a constant circular cross-section, we showed that the equation depends on neither the curvature nor the torsion of the cable. In fact, in this last case the new equation is equivalent to the cable equation for a straight cylindrical cable, where the voltage depends on the arc length parameter. This shows that the natural variables for the voltage are given by the cable geometric quantities. Additionally, we found an exact solution for an ideal cable with a particular non constant circular cross-section and zero curvature. In this last case, we show that when the radius increases the voltage decreases. Inspired in this ideal case, we rewrote the generalized cable equation as a diffusion equation with a source term. In this diffusion equation the source term and the diffusion coefficient are generated by the cable geometry. Furthermore, we provided numerical solutions to the new cable equation to different cable with swelling. These solutions show that when the derivatives of the cable radius are slowly changing functions the voltage is similar to voltage in a straight cylindrical cable. However, when these derivatives change significantly the voltage cable is reduced and, in a extreme case, it can be blocked. Moreover, these numerical results show that geometric inhomogeneities in a cable can change its voltage in it. The results of this paper might help us to understand the the behaviour of the voltage in focal axonal swellings which appears in some neurodegenerative diseases such as Alzheimer, Parkinson, HIV-associated dementia and Multiple Sclerosis \([6]\).

In this work we did not study the active case, but we can argue that when the cable has a constant circular cross-section the active case is not different from the
