Abstract
We describe a reduction process for symplectic principal $\mathbb{R}$-bundles in the presence of a momentum map. These types of structures play an important role in the geometric formulation of non-autonomous Hamiltonian systems. We apply this procedure to the standard symplectic principal $\mathbb{R}$-bundle associated with a fibration $\pi : M \to \mathbb{R}$. Moreover, we show a reduction process for non-autonomous Hamiltonian systems on symplectic principal $\mathbb{R}$-bundles. We apply these reduction processes to several examples.

1. Introduction

It is well known that the configuration space for a non-autonomous mechanical system is a smooth manifold which is fibered on the real line. So we have a fibration $\pi : M \to \mathbb{R}$, with respect to which the restricted phase space of momenta is the dual bundle $V^*\pi$ of the vertical bundle $V\pi$ of $\pi$ and the extended phase space of momenta is the cotangent bundle $T^*M$ of $M$.

In the presence of a Hamiltonian section (that is, a section of the canonical projection $\mu_\pi : T^*M \to V^*\pi$) and using the canonical symplectic structure of $T^*M$ (respectively, a suitable cosymplectic structure on $V^*\pi$), one may develop the extended (respectively, the restricted) Hamiltonian formalism (see section 2 and [9, 15, 18]).

We remark that $\mu_\pi : T^*M \to V^*\pi$ is a principal $\mathbb{R}$-bundle (an AV-bundle in the terminology of [9]). In addition, the principal action is symplectic and, thus, we have a symplectic principal $\mathbb{R}$-bundle. A non-autonomous Hamiltonian system is a symplectic principal $\mathbb{R}$-bundle $\mu : A \to V$ and a Hamiltonian section $h : V \to A$, that is, a section of the principal $\mathbb{R}$-bundle projection $\mu$. The Hamiltonian section $h$ induces a vector field on $V$ whose integral curves are the solutions of the dynamical equations for the Hamiltonian system (see section 5.1). In the particular case when $\mu : A \to V$ is a standard symplectic principal
\( \mathbb{R} \)-bundle (that is, \( \mu = \mu_\pi \) for some fibration \( \pi : M \to \mathbb{R} \)), we obtain the classical Hamilton equations. Moreover, all the tools used in the standard theory in geometric non-autonomous mechanics, as Lagrangian and Hamiltonian formalisms or variational formulation, appear in the framework of the AV bundles (see [9–12]).

On the other hand, in the context of autonomous mechanical systems, the phase space is represented by a symplectic manifold. A classical procedure, due to Marsden and Weinstein ([23]), called symplectic reduction, allows us to use the symmetry properties of a symplectic manifold in order to reduce the degrees of freedom of the system. Moreover, if an invariant Hamiltonian function is given on the unreduced symplectic manifold, one may obtain a Hamiltonian system on the reduced symplectic manifold.

Reduction theory may also be applied, for example, in order to obtain the symplectic structure on the coadjoint orbit of a Lie group \( G \) (see [1]). In the particular case when the unreduced symplectic manifold is the cotangent bundle of a manifold endowed with its canonical symplectic structure, a natural question arises as follows: is the reduced symplectic manifold a standard symplectic manifold (that is, a cotangent bundle endowed with its canonical symplectic structure)? An answer to this question is given by the so-called cotangent bundle reduction theory (see [16, 20, 21, 25]).

Although reduction theory goes back to the early roots of mechanics, it allows us to obtain many results about other geometric structures. Indeed, a similar idea may be used in order to reduce not only Poisson structures [22], but also cosymplectic, Kähler, hyperkähler, contact, \( f \)-structures, etc. and to obtain new examples of such kinds of manifolds [2, 7, 8, 13, 14].

The aim of this paper is to perform the reduction process in the framework of symplectic principal \( \mathbb{R} \)-bundles. We introduce the notion of symmetry of a symplectic principal \( \mathbb{R} \)-bundle and show that, under suitable regularity conditions, one may obtain a reduced symplectic principal \( \mathbb{R} \)-bundle. We apply this reduction process to the standard symplectic principal \( \mathbb{R} \)-bundle associated with a fibration. Finally, we prove that a non-autonomous Hamiltonian system with equivariant Hamiltonian section induces a non-autonomous Hamiltonian system on the reduced symplectic principal \( \mathbb{R} \)-bundle.

The paper is structured as follows. In section 2, we recall some basic facts about non-autonomous Hamiltonian systems which motivate the study of symplectic AV-differential geometry. In section 3, we introduce the category of symplectic principal \( \mathbb{R} \)-bundles and prove that the base manifold \( V \) of a symplectic principal \( \mathbb{R} \)-bundle is canonically equipped with a Poisson structure. Moreover, we relate the induced Poisson structures on the corresponding base spaces of an embedding of symplectic principal \( \mathbb{R} \)-bundles. In order to introduce a reduction process for symplectic principal \( \mathbb{R} \)-bundles, in section 4, we define the notion of a canonical action on a principal \( \mathbb{R} \)-bundle and prove the reduction theorem in the symplectic principal \( \mathbb{R} \)-bundle framework. As an example, in the last part of this section, we discuss the reduction of a standard symplectic principal \( \mathbb{R} \)-bundle \( \mu_\pi : T^*M \to V^*\pi \) associated with a fibration \( \pi : M \to \mathbb{R} \) which is invariant with respect to a free and proper action of a Lie group \( G \) on \( M \). In section 5, we develop the reduction of a non-autonomous Hamiltonian system on a symplectic principal \( \mathbb{R} \)-bundle. For this purpose, we use symplectic and cosymplectic reduction theory. In sections 4 and 5, we apply the reduction processes to the case of the bidimensional time-dependent damped harmonic oscillator and the time-dependent heavy top. In section 6, we show how to apply these reductions to the frame-independent formulation of the analytical mechanics in the Newtonian spacetime.

The paper concludes with our conclusions, a description of future research directions and an appendix in which we review some reduction processes for Poisson, symplectic and cosymplectic manifolds.
2. A motivation: non-autonomous Hamiltonian systems

It is well known that if a manifold $Q$ is the configuration space of an autonomous Hamiltonian system, then $T^*Q$ is the phase space of momenta. Moreover, using the canonical symplectic structure of $T^*Q$, one may describe the Hamilton equations in an intrinsic form (see, for instance, [1]).

For non-autonomous Hamiltonian systems, the situation is different (see, for instance, [9, 15, 18]). Namely, the configuration space is a manifold $M$ fibered over the real line. So we have a surjective submersion $\pi : M \to \mathbb{R}$. We will denote by $V\pi$ the vertical bundle of $\pi$ which is a vector bundle over $M$. Then, the restricted (respectively, extended) phase space of momenta is the dual bundle $V^*\pi$ of $V\pi$ (respectively, the cotangent bundle $T^*M$ of $M$).

We remark that $T^*M$ is a principal $\mathbb{R}$-bundle over $V^*\pi$ and the dual map $\mu_{\pi} : T^*M \to V^*\pi$ of the inclusion $i : V\pi \to TM$ is the principal bundle projection. The corresponding principal action $\psi_{\pi} : \mathbb{R} \times T^*M \to T^*M$ is defined by

$$\psi_{\pi}(s, \alpha_s) = \alpha_s + s \pi^*(dt)(x), \quad \text{for } s \in \mathbb{R} \text{ and } \alpha_s \in T^*_x M,$$

where $t$ is the usual coordinate on $\mathbb{R}$. Note that the principal action $\psi_{\pi}$ is symplectic with respect to the symplectic structure on $T^*M$. Moreover, the infinitesimal generator $Z_{\mu_{\pi}}$ of $\psi_{\pi}$ is the Hamiltonian vector field

$$Z_{\mu_{\pi}} = \mathcal{H}_{-\pi \circ \mu_{\pi}} \in \mathcal{X}(T^*M)$$

of the real function on $T^*M$ given by $-\pi \circ \mu_{\pi} : T^*M \to \mathbb{R}$, where $\pi_{\pi} : T^*M \to M$ is the canonical projection. One easily proves that

$$f \in C^\infty(T^*M) \text{ is } \mu_{\pi}-\text{projectable if and only if } Z_{\mu_{\pi}}(f) = 0. \tag{2.1}$$

On the other hand, the extended phase of momenta $T^*M$ admits a linear Poisson structure $\{\cdot, \cdot\}_{T^*M}$ induced by the canonical symplectic 2-form $\Omega_{\mu_{\pi}}$ on $T^*M$. Moreover, using (2.1) and the Jacobi identity of $\{\cdot, \cdot\}_{T^*M}$, one deduces that the subset $\mu_{\pi}^*(C^\infty(V^*\pi))$ of $C^\infty(T^*M)$ is closed with respect to $\{\cdot, \cdot\}_{T^*M}$. Therefore, there is a unique Poisson structure $\{\cdot, \cdot\}_{V^*\pi}$ on $V^*\pi$ such that (see [27])

$$\{f \circ \mu_{\pi}, h \circ \mu_{\pi}\}_{T^*M} = \{f, h\}_{V^*\pi} \circ \mu_{\pi}, \quad f, h \in C^\infty(V^*\pi). \tag{2.2}$$

Note that $\{\cdot, \cdot\}_{V^*\pi}$ is also linear and $\mu_{\pi} : T^*M \to V^*\pi$ is, by construction, a Poisson epimorphism.

In this setting, a Hamiltonian section is a section $h : V^*\pi \to T^*M$ of $\mu_{\pi}$. Using the Hamiltonian section, one may define a symplectic structure $(\omega_h, \eta)$ on $V^*\pi$ as follows:

$$\omega_h = h^*(\Omega_{\mu_{\pi}}), \quad \eta = \pi_{V^*\pi}^*(\pi^*(dt)) \tag{2.3}$$

with $\pi_{V^*\pi} : V^*\pi \to M$ the corresponding projection (for the definition of a cosymplectic structure, see the appendix). In fact, the 1-form $\eta$ given by (2.3) is just $\eta = -h^*(\mathcal{Z}_{\pi_{\mu_{\pi}}})\Omega_{\mu_{\pi}}$ and $\omega_h$ is well-known Poicard–Cartan 2-form.

On the other hand, since $\mu_{\pi}(h \circ \mu_{\pi})(\alpha_s) = \mu_{\pi}(\alpha_s)$, there exists a unique $F_h(\alpha_s) \in \mathbb{R}$ such that

$$\psi_{\pi}(-F_h(\alpha_s), \alpha_s) = h(\mu_{\pi}(\alpha_s)).$$

The extended Hamiltonian function associated with the Hamiltonian section $h$ is just the real $C^\infty$-function $F_h : T^*M \to \mathbb{R}$ and $(T^*M, \Omega, F_h)$ is the so-called homogeneous Hamiltonian system. It is easy to prove that the Hamiltonian vector field $\mathcal{H}_{F_h}$ of $F_h$ is $\mu_{\pi}$-projectable on the Reeb vector field $R_h$ of the cosymplectic structure $(\omega_h, \eta)$.
In what follows, we will give the local expressions of these elements. First, from the fact that $\pi : M \to \mathbb{R}$ is a submersion, one may consider the local coordinates $(t, q')$ on $M$ adapted to the submersion $\pi$ such that $\pi : M \to \mathbb{R}$ is the coordinate $t$. Denote by $(t, p, q', p_i)$ (respectively, $(t, q', p_i)$) the corresponding local coordinates on $T^*M$ (respectively, on $V^*\pi$). With respect to them, we have that 

$$\{t, q'\}_{V^*\pi} = \{t, p\}_{V^*\pi} = \{q', q'\}_{V^*\pi} = \{p_i, p_i\}_{V^*\pi} = 0, \quad \{q', p_i\}_{V^*\pi} = \delta^j_i,$$

and

$$\psi (s, (t, p, q', p_i)) = (t, s + p, q', p_i), \quad \mu (t, p, q', p_i) = (t, q', p_i).$$

If the local expression of a Hamiltonian section $h : V^*\pi \to T^*M$ is given by

$$h(t, q', p_i) = (t, -H(t, q, p), q', p_i),$$

then

$$F_0(t, p, q', p_i) = p + H(t, q', p_i)$$

and

$$\omega_{\text{h}} = d\eta \wedge \eta = dt.$$ 

Thus, the Reeb vector field $R_h$ of the cosymplectic structure $(\omega_{\text{h}}, \eta)$ and the Hamiltonian vector field $H\varphi_h$ have the following local expressions:

$$R_h = \frac{\partial}{\partial t} + \frac{\partial H}{\partial p} \frac{\partial}{\partial q'} - \frac{\partial H}{\partial q'} \frac{\partial}{\partial p}, \quad H\varphi_h = \frac{\partial}{\partial t} - \frac{\partial H}{\partial p} \frac{\partial}{\partial q'} + \frac{\partial H}{\partial p} \frac{\partial}{\partial q'}.$$

We remark that the integral curves of $R_h$ are just the Hamilton equations for $h$,

$$\frac{dq'}{dt} = \frac{\partial H}{\partial p}, \quad \frac{dp_i}{dt} = -\frac{\partial H}{\partial q'},$$

for all $i$.

### 3. The category of symplectic principal $\mathbb{R}$-bundles

Motivated by the example of the above section, one may introduce the notion of a symplectic principal $\mathbb{R}$-bundle as follows.

Let $\mu : A \to V$ be a principal $\mathbb{R}$-bundle (an AV-bundle in the terminology of [9]). We will denote by

$$\psi : \mathbb{R} \times A \to A, \quad (s, a) \mapsto \psi_s(a),$$

the corresponding principal action of the Lie group $(\mathbb{R}, +)$ on the manifold $A$.

In this case, the vertical distribution of $\mu$ has dimension 1 and it is generated by the infinitesimal generator $Z_\mu \in \mathfrak{X}(A)$ whose flow is $\psi_s$.

**Definition 3.1.** We will say that $\mu : (A, \Omega) \to V$ is a symplectic principal $\mathbb{R}$-bundle, if $\mu : A \to V$ is a principal $\mathbb{R}$-bundle and $\Omega$ is a symplectic structure on $A$ such that the associated principal action $\psi : \mathbb{R} \times A \to A$ is symplectic.

Note that the infinitesimal generator $Z_\mu$ of a symplectic principal $\mathbb{R}$-bundle $\mu : (A, \Omega) \to V$ is a locally Hamiltonian vector field.

**Example 3.2** (The standard symplectic principal $\mathbb{R}$-bundle associated with a fibration). If $\pi : M \to \mathbb{R}$ is a surjective submersion, then $T^*M$ is the total space of a symplectic principal $\mathbb{R}$-bundle over $V^*\pi$ (see section 2).
Example 3.3 (The standard symplectic principal \( \mathbb{R} \)-bundle associated with a fibration and a magnetic term). Let \( \pi : M \to \mathbb{R} \) be a surjective submersion with total space a manifold \( M \) of dimension \( n+1 \) and \( \beta \) a closed 2-form on \( M \). Consider the closed basic 2-form (the magnetic term) \( B = \pi^* \beta \) on \( T^*M \), where \( \pi_M : T^*M \to M \) is the canonical projection. An easy computation shows that \( B \) is invariant with respect to the \( \mathbb{R} \)-principal action of the standard symplectic principal \( \mathbb{R} \)-bundle \( \mu_\pi : T^*M \to V^* \pi \). Thus, if \( \Omega_M \) is the canonical symplectic form on \( T^*M \), \( \mu_\pi : (T^*M, \Omega_M - B) \to V^* \pi \) is a symplectic principal \( \mathbb{R} \)-bundle.

Now, we will prove a version of Darboux theorem for a symplectic principal \( \mathbb{R} \)-bundle.

Theorem 3.4. Let \( \mu : (A, \Omega) \to V \) be a symplectic principal \( \mathbb{R} \)-bundle with the infinitesimal generator \( Z_\mu \). Suppose that \( \dim A = 2n+2 \). Then, for any \( a \in A \), there exist the local coordinates \( (t, p, q^i, p_i) \) in a neighborhood \( U \) of \( a \) such that

(i) the local expression of \( \mu : A \to V \) is

\[
\mu(t, p, q^i, p_i) = (t, q^i, p_i),
\]

(ii) \( (t, p, q^i, p_i) \) are the Darboux coordinates for \( \Omega \).

Moreover, the local expression of the infinitesimal generator is \( Z_\mu = \frac{\partial}{\partial p} \).

Proof. The proof is based on the well-known construction of the Darboux coordinates (see, for instance, \cite[17]). Fix \( a \in A \). Since the vector field \( Z_\mu \) is locally Hamiltonian, there exists a local function \( t \) such that \( Z_\mu = -\mathcal{H}_t \). Choose a function \( p \) (eventually defined on a smaller open neighborhood of \( a \)) such that \( Z_\mu(p) = 1 \). Using the generalized Darboux theorem on the closed 2-form \( \Omega' = \Omega - dt \wedge dp \) of rank \( 2n \), one may complete \( t, p \) to a coordinate system \( (t, p, q^i, p_i) \) such that

\[
\Omega = dt \wedge dp + \sum_i dq^i \wedge dp_i.
\]

It follows that \( Z_\mu = -\mathcal{H}_t = \frac{\partial}{\partial p} \). Since \( \mu \) is the projection of \( A \) on \( A/(Z_\mu) \), the local expression of \( \mu \) is as in (3.1).

We will say that \( (t, p, q^i, p_i) \) in the previous theorem are canonical coordinates for the symplectic principal \( \mathbb{R} \)-bundle \( \mu \).

If \( \mu : (A, \Omega) \to V \) is a symplectic principal \( \mathbb{R} \)-bundle, then, using a well-known result on Poisson reduction (see, for instance \cite[17]), we have that the base manifold \( V \) may be canonically equipped with a Poisson structure as we show in the following result.

Proposition 3.5. Let \( \mu : (A, \Omega) \to V \) be a symplectic principal \( \mathbb{R} \)-bundle. Then, there exists a unique Poisson structure \( \{\cdot, \cdot\}_V \) on \( V \) such that \( \mu \) is a Poisson map, i.e.

\[
\{f \circ \mu, f' \circ \mu\}_A = \{f, f'\}_V \circ \mu, \quad \text{for any} \ f, f' \in C^\infty(V),
\]

where \( \{\cdot, \cdot\}_A \) is the Poisson bracket on \( A \) induced by the symplectic form \( \Omega \).

Note that for the canonical coordinates of \( \mu \), if \( (t, q^i, p_i) \) are the induced coordinates on \( V \), the corresponding local expression of the Poisson bracket on \( V \) with respect to these coordinates is as follows:

\[
\{t, q^i\}_V = \{t, p_i\}_V = \{q^i, p_i\}_V = \{p_i, p_j\}_V = 0, \quad \{q^i, p_j\}_V = \delta^i_j.
\]
Example 3.6. In the particular case when we have a standard symplectic principal $\mathbb{R}$-bundle $\mu_p : (T^*M, \Omega_M) \rightarrow V^*\pi$ associated with a fibration $\pi : M \rightarrow \mathbb{R}$, the Poisson structure is just the one described in (2.2).

Additionally, we suppose that we have a closed 2-form $\beta$ on $M$. Denote $B = \pi_M^*(\beta) \in \Omega^1(T^*M)$, where $\pi_M : T^*M \rightarrow M$ is the canonical projection, and by

- $\Lambda_{T^*M}^\beta$ and $\Lambda_{T^*M}^\beta$, the Poisson structures on $T^*M$ induced by the symplectic 2-form $\Omega_M$ and $\Omega_M - B$, respectively;
- $\Lambda_{V^*\pi}$ and $\Lambda_{V^*\pi}$ the Poisson structures on $V^*\pi$ induced on the base space of the symplectic principal $\mathbb{R}$-bundles $\mu_p : (T^*M, \Omega_M) \rightarrow V^*\pi$ and $\mu_\pi : (T^*M, \Omega_M - B) \rightarrow V^*\pi$, respectively.

If $\{\cdot, \cdot\}_{T^*M}$ and $\{\cdot, \cdot\}_{T^*M}$ are the Poisson brackets on $T^*M$ induced by the symplectic forms $\Omega_M$ and $\Omega_M - B$, respectively, then one may easily prove that

$$\{F, F'\}_{T^*M}^\beta = \{F, F'\}_{T^*M} + B(\mathcal{H}_F, \mathcal{H}_F),$$

for any $F, F' \in C^\infty(T^*M)$, where $\mathcal{H}_F, \mathcal{H}_F \in \mathcal{X}(T^*M)$ are the Hamiltonian vector fields of $F, F'$ with respect to the symplectic structure $\Omega_M$ (see [20]).

Alternatively, (3.3) may be written in terms of the vertical lift of $\beta$. We recall that for a vector bundle $\tau : E \rightarrow Q$, the vertical lift $\gamma^v$ of a section $\gamma$ of $\wedge^2 E \rightarrow Q$ is a $p$-vector on $E$. In fact, if $(q')$ are the local coordinates on an open subset $U$ of $Q$, $\{e_i\}$ is a local basis of $\Gamma(E)$ and $\gamma = \gamma^{i_1\cdots i_p} e_{i_1} \wedge \cdots \wedge e_{i_p}$ on $U$,

$$\gamma^v = \gamma^{i_1\cdots i_p} \frac{\partial}{\partial y^{i_1}} \wedge \cdots \wedge \frac{\partial}{\partial y^{i_p}},$$

where $(q', y^p)$ are the corresponding local coordinates on $E$. Then, (3.3) may be rewritten as

$$\{F, F'\}_{T^*M}^\beta = \{F, F'\}_{T^*M} + \beta^v(dF, dF').$$

Indeed, it is sufficient to prove that if $F$ and $F'$ are the lineal or basic functions on $T^*M$, then $\beta^v(dF, dF') = B(\mathcal{H}_F, \mathcal{H}_F)$.

Therefore, from (3.4), we deduce that the Poisson structures $\Lambda_{T^*M}^\beta$ and $\Lambda_{T^*M}^\beta$ are related as follows:

$$\Lambda_{T^*M}^\beta = \Lambda_{T^*M} + \beta^v.$$  \hfill (3.5)

On the other hand, we consider the section $\tilde{\beta}$ of the vector bundle $\wedge^2 V^*\pi \rightarrow M$ defined by

$$\tilde{\beta}(x) = \beta(x)|_{V_x \times \Lambda_{V^*\pi}^\cdot}, \quad \text{for any } x \in N.$$

If $\{\cdot, \cdot\}_{V^*\pi}$ and $\{\cdot, \cdot\}_{V^*\pi}$ denote the Poisson brackets on $V^*\pi$ induced by $\Lambda_{V^*\pi}^\beta$ and $\Lambda_{V^*\pi}$, respectively, from (3.4) and proposition 3.5, we have that

$$\{f, f'\}_{V^*\pi}^\beta \circ \mu_\pi = \{f, f'\}_{V^*\pi} + \beta^v(\mu_\pi^*(df), \mu_\pi^*(df')),$$

for $f, f' \in C^\infty(V^*\pi)$.

Moreover, one may easily prove that

$$\beta^v(\mu_\pi^*(df), \mu_\pi^*(df')) = \tilde{\beta}^v(df, df') \circ \mu_\pi.$$

Thus,

$$\Lambda_{V^*\pi}^\beta = \Lambda_{V^*\pi} + \tilde{\beta}^v.$$  \hfill (3.7)
In the last part of this section, we will study morphisms in the category of symplectic principal \( \mathbb{R} \)-bundles.

Let \( \mu : A \to V \) and \( \mu' : A' \to V' \) be two principal \( \mathbb{R} \)-bundles with principal actions \( \psi \) and \( \psi' \); respectively. Suppose that the function \( \varphi : A \to A' \) is a principal \( \mathbb{R} \)-bundle morphism, that is, \( \varphi \) is equivariant with respect to the principal actions, i.e.

\[
\varphi \circ \psi_s = \psi'_s \circ \varphi, \quad \text{for any } s \in \mathbb{R}. \tag{3.8}
\]

From (3.8), one deduces that the infinitesimal generators \( Z_\mu \) and \( Z_{\mu'} \) of \( \mu : A \to V \) and \( \mu' : A' \to V' \), respectively, are \( \varphi \)-related. Moreover, by passing to the quotient and using (3.8), one may define a map \( \varphi^V : V \to V' \) characterized by the following relation:

\[
\mu' \circ \varphi = \varphi^V \circ \mu. \tag{3.9}
\]

Note that, since \( \mu \) is a submersion, \( \varphi^V \) is smooth. The following diagram illustrates the situation:

\[
\begin{array}{ccc}
A & \xrightarrow{\varphi} & A' \\
\downarrow{\mu} & & \downarrow{\mu'} \\
V & \xrightarrow{\varphi^V} & V'
\end{array}
\]

Now suppose that \( \psi \) is a principal \( \mathbb{R} \)-bundle embedding. Then \( \varphi^V \) is also an embedding. In fact, using (3.8), (3.9) and the fact that \( \mu \circ \psi_s = \mu \), for all \( s \), we deduce that \( \varphi^V \) is an injective immersion. Moreover, standard topological arguments show that the map \( \varphi^V : V \to \varphi^V(V) \) is a homeomorphism.

On the other hand, if \( \varphi : A \to A' \) is a diffeomorphism, then \( \varphi^V \) also is a diffeomorphism. Indeed,

\[
(\varphi^V)^{-1} = (\varphi^{-1})^V.
\]

**Definition 3.7.** Let \( \mu : (A, \Omega) \to V \) and \( \mu' : (A', \Omega') \to V' \) be the symplectic principal \( \mathbb{R} \)-bundles. A smooth function \( \varphi : A \to A' \) is said to be a symplectic principal \( \mathbb{R} \)-bundle morphism if \( \varphi \) is a principal \( \mathbb{R} \)-bundle morphism such that \( \varphi^* \Omega' = \bar{\Omega} \).

If we change the word ‘morphism’ by ‘embedding’ (respectively, ‘isomorphism’) in the previous definition, we obtain the notion of a symplectic principal \( \mathbb{R} \)-bundle embedding (respectively, a symplectic principal \( \mathbb{R} \)-bundle isomorphism). In what follows, we relate the Poisson structures induced on a symplectic principal \( \mathbb{R} \)-bundle embedding.

First, we remark that in general, if \( \varphi : (A, \Omega) \to (A', \Omega') \) is a symplectic morphism, \( \varphi \) is not a Poisson morphism with respect to the corresponding Poisson structures \( \Lambda_A \) and \( \Lambda_{A'} \) (see, for instance, [25]). In fact, if \( \varphi : (A, \Omega) \to (A', \Omega') \) is a symplectic embedding, then one may give a relation between the corresponding Poisson structures \( \Lambda_A \) and \( \Lambda_{A'} \) on \( A \) and \( A' \), respectively. Under the identification of the tangent space \( T_aA \) at \( a \in A \) with \( T_a\varphi(T_aA) \), we have

\[
T^*_{\varphi(a)}A' = (T_aA)^\nu \oplus ((T_aA)^\Omega)^\nu = (T_aA)^\nu \oplus (\#_{\Lambda_{A'}}(T_aA)^\nu)^\nu, \tag{3.10}
\]

where \( (T_aA)^\Omega \) denotes the symplectic orthogonal space of \( T_a\varphi(T_aA) \equiv T_aA \) with respect to the symplectic form \( \Omega_{\varphi(a)} \) on \( T_{\varphi(a)}A' \) and \( W^\nu \) denotes the annihilator of a subspace \( W \subset T_{\varphi(a)}A' \) in \( T^*_{\varphi(a)}A' \).

Denote by \( \tilde{P}_a : T^*_{\varphi(a)}A' \to ((T_aA)^\Omega)^\nu \) and \( \tilde{Q}_a : T^*_{\varphi(a)}A' \to (T_aA)^\nu \) the corresponding projectors associated with splitting (3.10). Note that if \( \alpha \in (T_aA)^\nu \), then \( T^\nu_{\varphi(a)}(\alpha) = 0 \) and
\( \tilde{P}_a(\alpha) = 0. \) Using these facts, we deduce that the Poisson structures \( \Lambda_A \) and \( \Lambda_A' \) are related as follows:

\[
\Lambda_A(a)(\varphi^*(\alpha_1'), \varphi^*(\alpha_2')) = \Lambda_A(\varphi(a))(\alpha_1', \alpha_2') - \Lambda_A(\varphi(a))(\tilde{Q}_a(\alpha_1'), \tilde{Q}_a(\alpha_2'))
\]

(3.11) for all \( \alpha_1', \alpha_2' \in T_{\varphi(a)}A'. \)

Now, let \( \varphi : A \to A' \) be an embedding of the principal \( \mathbb{R} \)-bundles \( \mu : (A, \Omega) \to V \) and \( \mu' : (A', \Omega') \to V' \) and let \( \varphi^V : V \to V' \) be the corresponding embedding between the base spaces \( V \) and \( V' \). Using (3.9), (3.10) and the fact that the infinitesimal generators \( Z_{\mu} \) and \( Z_{\mu'} \) are \( \varphi \)-related, one may obtain that

\[
T_{\varphi^V(v)}V' = T_vV \oplus T_{\varphi(a)}\mu'((T_aA)^\mathbb{R}) \quad \text{with } v = \mu(a).
\]

Moreover, from (3.9) and since \( \dim(T_vV)^\mathbb{R} = \dim(T_aA)^\mathbb{R} \), it follows that

\[
(T_aA)^\mathbb{R} = T_{\varphi(a)}\mu((T_vV)^\mathbb{R}),
\]

with \( (T_vV)^\mathbb{R} \) being the annihilator of \( T_vV \) in \( T_{\varphi^V(v)}V' \). Therefore, from the fact that \( \mu' \) is a Poisson map, we deduce that

\[
T_{\varphi^V(v)}V' = T_vV^\mathbb{R} \oplus ((\sharp_{\Lambda_{\mu'}}(T_vV)^\mathbb{R}))^\mathbb{R}
\]

and the first projector \( \tilde{q}_v : T_{\varphi^V(v)}V' \to (T_vV)^\mathbb{R} \).

Now, from (3.2), (3.9) and (3.11) and the relation \( \tilde{Q}_a \circ T_{\varphi^V(a)}\mu' = T_{\varphi(a)}\mu' \circ \tilde{q}_v \), we obtain the following.

**Proposition 3.8.** Let \( \varphi : A \to A' \) be an embedding of the symplectic principal \( \mathbb{R} \)-bundles \( \mu : (A, \Omega) \to V \) and \( \mu' : (A', \Omega') \to V' \) and let \( \varphi^V : V \to V' \) be the corresponding embedding between the base spaces \( V \) and \( V' \). Then the Poisson structures \( \Lambda_V \) and \( \Lambda_{V'} \) induced on \( V \) and \( V' \), respectively, by \( \mu \) and \( \mu' \), are related by

\[
\Lambda_V(v)((\varphi^V)^*(\sigma_1'), (\varphi^V)^*(\sigma_2')) = \Lambda_{V'}(\varphi^V(v))(\sigma_1', \sigma_2') - \Lambda_{V'}(\varphi^V(v))(\tilde{Q}_v(\sigma_1'), \tilde{Q}_v(\sigma_2'))
\]

with \( v \in V \) and \( \sigma_1', \sigma_2' \in T_{\varphi^V(v)}V' \). If \( \varphi : A \to A' \) is an isomorphism of principal \( \mathbb{R} \)-bundles, then \( \varphi^V : V \to V' \) is a Poisson isomorphism.

### 4. Reduction of symplectic principal \( \mathbb{R} \)-bundles

In this section, we describe the reduction process of a symplectic principal \( \mathbb{R} \)-bundle in the presence of a momentum map.

#### 4.1. Canonical actions and momentum maps

In this subsection, we consider special types of actions which are compatible with the symplectic principal \( \mathbb{R} \)-bundle in a certain sense.

**Definition 4.1.** We say that an action \( \phi : G \times A \to A \) is a canonical action on the symplectic principal \( \mathbb{R} \)-bundle \( \mu : (A, \Omega) \to V \) with principal action \( \psi : \mathbb{R} \times A \to A \), if the following conditions hold:

---

8
(i) \( \phi \) is a symplectic action;
(ii) the actions \( \psi \) and \( \phi \) commute, that is,
\[
\phi_g \circ \psi_s = \psi_s \circ \phi_g, \quad \text{for any} \ g \in G, \ s \in \mathbb{R};
\]
(iii) the 1-form \( \xi_\mu = i_{\partial_\mu} \Omega \) is basic with respect to \( \phi \), i.e. \( \xi_\mu (\xi_A) = 0 \) for any \( \xi \in g \), where \( \xi_A \) is the infinitesimal generator of \( \phi \) defined by \( \xi \).

We will see that, for a canonical action on \( \mu \) with a momentum map \( J : A \rightarrow g^* \), one may induce canonically a Poisson action with a momentum map on \( V \) (for the definition of a momentum map associated with the Poisson action, see the appendix). In fact, let \( \xi \) be an element of the Lie algebra \( g \). Using that \( \xi_\mu \) is basic, it follows that
\[
Z_\mu (J_\xi) = i_{\xi_A} \Omega (Z_\mu) = -\xi_\mu (\xi_A) = 0.
\]
Therefore, the function \( J_\xi : A \rightarrow \mathbb{R} \) is constant on the fibers of \( \mu \) and thus,
\[
J \circ \psi_s = J, \quad \text{for any} \ s.
\]
Using this fact and (4.1), we may define the action \( \phi^V : G \times V \rightarrow V \) of \( G \) on \( V \) and the map \( J^V : V \rightarrow g^* \) characterized by
\[
\phi_g^V \circ \mu = \mu \circ \phi_g, \quad \text{for any} \ g \in G,
\]
\[
J^V \circ \mu = J.
\]
Note that, by construction, \( \mu \) is equivariant with respect to the actions \( \phi \) and \( \phi^V \). So \( \mu \) transforms the infinitesimal generator \( \xi_A \in \mathfrak{X}(A) \) of \( \xi \in g \) with respect to the action \( \phi \) into the infinitesimal generator \( \xi_V \in \mathfrak{X}(V) \) of \( \xi \) with respect to the action \( \phi^V \), that is,
\[
T_\mu \mu (\xi (a)) = \xi_V (\mu (a)), \quad \text{for any} \ a \in A.
\]
Moreover, we have

**Proposition 4.2.** If \( \phi : G \times A \rightarrow A \) is a canonical action equipped with a momentum map \( J : A \rightarrow g^* \), then

(i) \( \phi^V : G \times V \rightarrow V \) is a Poisson action,

(ii) \( J^V : V \rightarrow g^* \) is a momentum map associated with \( \phi^V \) and if \( J \) is \( \text{Ad}^* \)-equivariant, then so is \( J^V \).

**Proof.** For any \( g \in G \), \( \phi^V_g : V \rightarrow V \) is just the map induced by the symplectic principal \( \mathbb{R} \)-bundle isomorphism \( \phi_g : A \rightarrow A \). Thus, using proposition 3.8, it follows that \( \phi^V_g \) is a Poisson map.

Now we prove that \( J^V \) is a momentum map, that is, \( \xi_V = H_{J^V} \), for any \( \xi \in g \). In fact, for any \( f \in C^\infty (V) \) and \( a \in A \), one has, from (3.2), (4.5) and (4.6), that
\[
(\xi_V(f))(\mu(a)) = \xi(a)(f \circ \mu) = H_{J^V}(\mu)(f \circ \mu) = \left[ f \circ \mu, J^V \circ \mu \right]_A(a)
\]
\[
= \left[ f, J^V \right]_V(\mu(a)) = H_{J^V}(f)(\mu(a)).
\]
Since \( a \) is an arbitrary element of \( A \) and \( \mu \) is surjective, we obtain that \( \xi_V = H_{J^V} \).

If \( J \) is \( \text{Ad}^* \)-equivariant (see the appendix), then for any \( v = \mu (a) \in V \) and for any \( g \in G \),
\[
\text{Ad}_{\mu^{-1}}^*(J^V(v)) = \text{Ad}_{\mu^{-1}}^*(J(a)) = J(\phi_g(a)) = J^V(\phi^V_g(v)).
\]
Thus, \( J^V \) is \( \text{Ad}^* \)-equivariant. \( \square \)
4.2. The reduction process of symplectic principal \( \mathbb{R} \)-bundles

In this subsection, we will use the results of the appendix to reduce a symplectic principal \( \mathbb{R} \)-bundle equipped with a canonical action and an \( \text{Ad}^* \)-equivariant momentum map.

Suppose that \( \mu: (A, \Omega) \to V \) is a symplectic principal \( \mathbb{R} \)-bundle equipped with a canonical action \( \phi: G \times A \to A \) of a Lie group \( G \) with an \( \text{Ad}^* \)-equivariant momentum map \( J: A \to g^* \). One may induce a Poisson action \( \phi^V: G \times V \to V \) on \( V \) with an \( \text{Ad}^* \)-equivariant momentum map \( \phi^V: V \to g^* \). Assume that \( \phi^V \) is free and proper. Then, so is \( \phi \). Moreover, \( J \) and \( J^V \) are submersions and any element of \( g^* \) is a regular value of both maps.

If \( v \in g^* \), from the Marsden–Weinstein reduction theorem (respectively, Poisson reduction theorem), we may induce a reduced symplectic structure and, using (4.10), we may induce a reduced symplectic structure on the reduced space \( A_{\mu} = J^{-1}(v)/G_v \) (respectively, \( V_v = (J^V)^{-1}(v)/G_v \)). Let us prove that \( A_v \) and \( V_v \) are the total space and the base manifold, respectively, of a reduced principal \( \mathbb{R} \)-bundle \( \mu_v: A_v \to V_v \).

The map \( \mu_v: A_v \to V_v \) is defined as follows. Using (4.5), it follows that the restriction \( \mu: J^{-1}(v) \to (J^V)^{-1}(v) \) of \( \mu \) on the closed submanifold \( J^{-1}(v) \) is a surjective submersion. Moreover, we have that the actions \( \phi: G_v \times J^{-1}(v) \to J^{-1}(v) \) and \( \phi^V: G_v \times (J^V)^{-1}(v) \to (J^V)^{-1}(v) \) of the isotropy group \( G_v \) on \( J^{-1}(v) \) and \( (J^V)^{-1}(v) \), respectively, are free and proper and \( \mu \) is equivariant with respect to them. Denote by \( \mu_v: A_v = J^{-1}(v)/G_v \to V_v = (J^V)^{-1}(v)/G_v \) the induced map on the quotient spaces which is characterized by

\[
\mu_v \circ \pi_v = \pi_v^V \circ \mu.
\]

where \( \pi_v: J^{-1}(v) \to A_v \) and \( \pi_v^V: (J^V)^{-1}(v) \to V_v \) are the corresponding canonical projections. Note that \( \mu_v \) is a surjective submersion.

Moreover, using (4.1) and (4.3), we have that the principal action \( \psi: \mathbb{R} \times A \to A \) restricts to an action of \( \mathbb{R} \) on \( J^{-1}(v) \). So it defines an action of \( \mathbb{R} \) on \( A_v \), \( \psi_v: \mathbb{R} \times A_v \to A_v \), characterized by

\[
(\psi_v)(a) \circ \pi_v = \pi_v \circ \psi_v.
\]

In addition, we may prove the following result.

**Theorem 4.3.** Let \( \mu: (A, \Omega) \to V \) be a symplectic principal \( \mathbb{R} \)-bundle equipped with a canonical action \( \phi: G \times A \to A \) and an \( \text{Ad}^* \)-equivariant momentum map \( J: A \to g^* \).

Suppose that the induced action \( \phi^V: G \times V \to V \) is free and proper. Then, for any \( v \in g^* \), \( \mu_v: (A_v, \Omega_v) \to V_v \) is a symplectic principal \( \mathbb{R} \)-bundle with principal action defined by (4.8), where \( \Omega_v \) is the reduced symplectic structure on the reduced space \( A_v = J^{-1}(v)/G_v \) and \( \pi_v \)-projectable. Its \( \pi_v \)-projection is the infinitesimal generator \( Z_{\mu_v} \) of \( \mu_v \).

**Proof.** First of all, we will see that \( \psi_v \) is a free action. Indeed, suppose that \( (\psi_v)_* (\pi_v (a)) = \pi_v (a) \) for \( a \in J^{-1}(v) \). Then, from (4.1) and (4.8), we deduce that there exists \( g \in G_v \) such that

\[
a = \psi_v (\phi_v (a)).
\]

This implies that

\[
\mu (a) = \mu (\psi_v (\phi_v (a))) = \mu (\phi_v (a))
\]

and, using (4.4), it follows that \( \phi^V (\mu (a)) = \mu (a) \). Thus, since \( \phi^V \) is a free action, we obtain that \( g = e \). Therefore, from (4.9), we conclude that \( s = 0 \).
Next, we will prove that the fibers of \( \mu_v \) are just the orbits of the action of \( \mathbb{R} \) on \( A_v = J^{-1}(v)/G_v \). In other words, we will see that

\[
(\psi_v)_*(a)(\mathbb{R}) = (\mu_v)\left( (\mu_v)_*(a) \right), \quad \text{for } a \in J^{-1}(v).
\]

In fact, a straightforward computation, using (4.4), (4.7) and (4.8), proves the result. Consequently, \( \mu_v : A_v \to V_v \) is a principal \( \mathbb{R} \)-bundle.

Now, as we know, the action \( \psi : \mathbb{R} \times A \to A \) restricts to an action of \( \mathbb{R} \) on \( J^{-1}(v) \). This implies that the restriction on \( J^{-1}(v) \) of the infinitesimal generator \( Z_{\mu_1} \) of \( \mu_1 \) is tangent to \( J^{-1}(v) \) and \( Z_{\mu_1}(J^{-1}(v)) \) is just the infinitesimal generator of the action of \( \mathbb{R} \) on \( J^{-1}(v) \).

In addition, since the projection \( \pi_v \) is equivariant, we obtain that \( Z_{\mu_1}(J^{-1}(v)) \) is \( \pi_v \)-projectable and its projection is the infinitesimal generator \( Z_{\mu_1} \) of \( \mu_1 \).

Finally, we prove that \( Z_{\mu_1} \) is a locally Hamiltonian vector field. We will show that the flow \( (\psi_v)_* : A_v \to A_v \) of \( Z_{\mu_1} \) preserves the symplectic form \( \Omega_v \). In fact, using (4.8), (A.2) (see the appendix) and the invariance of \( \Omega \) under the action of \( \psi_v \), we obtain

\[
\pi_v^*(\psi_v)_*^*\Omega_v = \psi_v^*(\pi_v^*\Omega_v) = \psi_v^*(i_v^*\Omega) = i_v^*\Omega = \pi_v^*\Omega_v.
\]

As a consequence, we have that \( (\psi_v)_*^*\Omega_v = \Omega_v \). \( \square \)

From proposition 3.5, the symplectic 2-form \( \Omega_v \) on \( V_v \) induces a Poisson structure \( \{ \cdot, \cdot \} \) on \( V_v \). On the other hand, using theorem A.1, we have that \( V_v \) is equipped with a reduced Poisson structure. The following result proves that these structures are the same.

**Proposition 4.4.** Under the same hypotheses as in theorem 4.3, the reduced Poisson bracket \( \{ \cdot, \cdot \}_v \) on \( V_v \) is just the one induced by the symplectic principal \( \mathbb{R} \)-bundle \( \mu_v : A_v \to V_v \).

**Proof.** Let \( f, f' \) be functions on \( V_v \) and \( \pi_v^* \) \( (v) \in V_v \), with \( v \in (J^V)^{-1}(v) \). Choose \( a \in J^{-1}(v) \) such that \( \mu(a) = v \). The bracket \( \{ \cdot, \cdot \}_v \) is characterized by

\[
\left\{ f, f' \right\}_v(\pi_v^* (v)) = \{ f, f' \}_V(v),
\]

where \( f \) and \( f' \in C^\infty(V) \) are the arbitrary \( G \)-invariant extensions of \( f \circ \pi_v^* \) and \( f' \circ \pi_v^* \), respectively.

Note that \( f \circ \mu, f' \circ \mu \in C^\infty(A_v) \) are the \( G \)-invariant extensions of \( f \circ \pi_v^* \circ \mu_{J^{-1}(v)} \) and \( f' \circ \pi_v^* \circ \mu_{J^{-1}(v)} \), respectively. Applying theorem A.2 (see the appendix), we obtain that the Poisson bracket \( \{ \cdot, \cdot \}_A \) on \( A_v \) induced by \( \Omega_v \) may be expressed as follows:

\[
\left\{ f, f' \right\}_A(\pi_v(a)) = \{ f \circ \mu, f' \circ \mu \}_A(a).
\]

Therefore, using (3.2) referred to \( \mu \) and \( \mu_v \), we have

\[
\left\{ f, f' \right\}_{V_v}(\pi_v^* (v)) = \left\{ f \circ \mu_v, f' \circ \mu_v \right\}_A(\pi_v(a)) = \left\{ f \circ \mu, f' \circ \mu \right\}_A(a) = \left\{ f_v, f'_v \right\}_{V_v}(\pi_v^* (v)).
\]

This proves that \( \left\{ f, f' \right\}_{V_v} = \left\{ f_v, f'_v \right\}_v \). \( \square \)

### 4.3. The standard case

In this subsection, we apply the reduction procedure to the standard symplectic principal \( \mathbb{R} \)-bundle \( \mu : (T^*M, \Omega_M) \to V^* \pi \) associated with a surjective submersion \( \pi : M \to \mathbb{R} \) (see section 2 and example 3.2), where \( \Omega_M \) is the canonical symplectic structure on \( T^*M \).

Suppose that \( \phi : G \times M \to M \) is an action of a connected Lie group \( G \) on the manifold \( M \). The lifted action \( T^* \phi : G \times T^*M \to T^*M \) is symplectic with respect to the standard symplectic
structure $\Omega_M$ on $T^*M$ and it admits an $Ad^*$-equivariant momentum map $J : T^*M \to \mathfrak{g}^*$ given by

$$J(\alpha_x)(\xi) = J_\xi(\alpha_x) = \alpha_x(\xi_M(x)),$$

for any $\xi \in \mathfrak{g}$, \hspace{1cm} (4.10)

where $\xi_M \in \mathfrak{X}(M)$ is the infinitesimal generator of $\phi$ associated with $\xi$.

The following result gives a sufficient condition for $T^*\phi$ to be a canonical action on the standard symplectic principal $\mathbb{R}$-bundle $\mu_{\pi}$.

**Proposition 4.5.** Let $\pi : M \to \mathbb{R}$ be a surjective submersion. Denote by $\mu_{\pi} : (T^*M, \Omega_M) \to (V^*\pi, \pi)$ the corresponding standard symplectic principal $\mathbb{R}$-bundle and by $T^*\phi : G \times T^*M \to T^*M$ the cotangent lift of an action $\phi : G \times M \to M$ of a connected Lie group $G$ on $M$. If $\pi$ is $G$-invariant, i.e. $\pi \circ \phi_g = \pi$ for any $g \in G$, then $T^*\phi$ is a canonical action on $\mu_{\pi}$.

**Proof.** Recall that the infinitesimal generator $\xi_{T^*M}$ of the action $T^*\phi$ associated with an element $\xi$ of $\mathfrak{g}$ is just the Hamiltonian vector field of the linear function $\xi_M \in C^\infty(T^*M)$ associated with $\xi_M \in \mathfrak{X}(M)$.

Moreover, since $\pi_M : T^*M \to M$ is equivariant with respect to the actions $T^*\phi$ and $\phi$, the vector fields $\xi_{T^*M}$ and $\xi_M$ are $\pi_M$-related. Now, using that $Z_{\pi_M}$ is the Hamiltonian vector field of the function $-\pi \circ \pi_M$ and that $\pi$ is $G$-invariant, we obtain

$$\Omega_M(\xi_{T^*M}, Z_{\pi_M}) = H_{\xi_M}(\pi \circ \pi_M) = \xi_{T^*M}(\pi \circ \pi_M) = \xi_M(\pi) \circ \pi_M = 0.$$

Thus, $\xi_{\pi_M} = i_{Z_{\pi_M}} \Omega_M$ is basic. It also follows that

$$[Z_{\pi_M}, \xi_{T^*M}] = -[H_{\pi \circ \pi_M}, H_{\xi_M}] = H(\pi \circ \pi_M, \xi_M)_{T^*M} = 0$$

for all $\xi \in \mathfrak{g}$. Since $G$ is connected, the actions $\psi$ and $T^*\phi$ commute. \hfill $\square$

Moreover, we note that if $\phi$ is free and proper, so is $(T^*\phi)^{V^*\pi}$.

The rest of the subsection is devoted to giving sufficient conditions for the reduced symplectic principal $\mathbb{R}$-bundle obtained from a standard principal $\mathbb{R}$-bundle to be again standard. We will use some well-known results of the cotangent bundle reduction theory (see, for instance, [20]).

Suppose that a connected Lie group $G$ acts freely and properly on a manifold $M$.

We assume that we have a $G$-invariant surjective submersion $\pi : M \to \mathbb{R}$. Using theorem 4.3, we obtain a reduced symplectic principal $\mathbb{R}$-bundle

$$(\mu_{\pi})_v : ((T^*M)_v, (\Omega_M)_v) \to (V^*\pi)_v,$$

where $((T^*M)_v = J^{-1}(v)/G_v$ and $(V^*\pi)_v = (J^{V^*\pi})^{-1}(v)/G_v$.

On the other hand, since $\pi$ is $G$-invariant, there exists a unique surjective submersion $\pi_{1,v}^* : M/G_v \to \mathbb{R}$ such that

$$\pi_{1,v}^* \circ \pi_{M,G_v} = \pi,$$

(4.11)

where we have denoted by $\pi_{M,G_v} : M \to M/G_v$ the $v$-shape space. Thus, we may consider the corresponding standard symplectic principal $\mathbb{R}$-bundle

$$(\mu_{\pi_{1,v}})_v : (T^*(M/G_v), \Omega_{M/G_v}) \to (V^*\pi_{1,v}^*)_v,$$

with $\Omega_{M/G_v}$ being the canonical symplectic 2-form on the cotangent bundle $T^*(M/G_v)$.

We will prove that, under a suitable hypothesis, the reduced symplectic principal $\mathbb{R}$-bundle $(\mu_{\pi})_v$ may be embedded into the standard symplectic principal $\mathbb{R}$-bundle $\mu_{\pi_{1,v}}$, where the total space $T^*(M/G_v)$ will be equipped with the canonical symplectic form $\Omega_{M/G_v}$ deformed by a magnetic term.
The magnetic term is defined as follows. Consider the action $\phi_v : G \times M \rightarrow M$ deduced from $\phi : G \times M \rightarrow M$. Its cotangent lift $T^*\phi_v : G_v \times T^*M \rightarrow T^*M$ has an $\text{Ad}^*$-equivariant momentum map $J_v : T^*M \rightarrow g^*_v$ obtained by restricting $J$, that is, for $\alpha_x \in T^*_x M$,

$$J_v(\alpha_x) = J(\alpha_x)_{|g_v}.$$  \hfill (4.12)

Let $v' = v|_{g_v}$ be the restriction of $v$ on $g_v$. Since the actions are free and proper, $v$ and $v'$ are the regular values for $J$ and $J_v$, respectively. Note that the inclusion of submanifolds $i : J^{-1}(v) \hookrightarrow J_v^{-1}(v')$ is a $G_v$-invariant embedding.

We will use the following assumption.

**(MT)** There exists a $G_v$-invariant 1-form $\lambda_v$ on $M$ with values in $J_v^{-1}(v')$.

In fact, if $A : TM \rightarrow g$ is the connection 1-form associated with a principal connection on the principal $G$-bundle $\pi_{M,G} : M \rightarrow M/G$, then $\lambda_v = v \circ A$ defines a 1-form on $M$ which satisfies condition (MT) (for more details, see [20]).

Now, using that the 2-form $\mathsf{d}\lambda_v$ is basic with respect to the projection $\pi_{M,G}$, we deduce that there exists a unique closed 2-form $\beta_{\lambda_v}$ on $M/G_v$ such that

$$\pi_{M,G}^* \beta_{\lambda_v} = \mathsf{d}\lambda_v.$$

If we define the 2-form $B_{\lambda_v}$ on $T^*(M/G_v)$ as

$$B_{\lambda_v} = \pi_{M,G}^* \beta_{\lambda_v},$$

where $\pi_{M,G}^* : T^*(M/G_v) \rightarrow M/G_v$ is the cotangent bundle projection, we may consider the corresponding standard symplectic principal $\mathbb{R}$-bundle

$$\mu_{\pi_{1,v}} : (T^*(M/G_v), \Omega_{M/G_v} - B_{\lambda_v}) \rightarrow V^* \pi_{1,v}$$

with the magnetic term $B_{\lambda_v}$ (see example 3.3). The form $B_{\lambda_v}$ is usually called the magnetic term associated with $\lambda_v$.

The main theorem of this section is as follows.

**Theorem 4.6.** Let $\phi : G \times M \rightarrow M$ be a free and proper action of a connected Lie group $G$ on the manifold $M$ and $\pi : M \rightarrow \mathbb{R}$ a $G$-invariant surjective submersion. Let $v \in g^*$ and $\pi_{1,v} : M/G_v \rightarrow \mathbb{R}$ be the surjective submersion obtained from $\pi$ by passing to the quotient. Choose a $G_v$-invariant 1-form $\lambda_v \in \Omega^1(M)$ with values in $J_v^{-1}(v')$. Then there is a symplectic principal $\mathbb{R}$-bundle embedding

$$\varphi_{\lambda_v} : (T^*M)_v \rightarrow T^*(M/G_v)$$

between the reduced symplectic principal $\mathbb{R}$-bundle $(\mu_{\pi_v})_v : ((T^*M)_v, (\Omega_{M,v})) \rightarrow (V^* \pi)_v$ and the standard symplectic principal $\mathbb{R}$-bundle $\mu_{\pi_{1,v}} : (T^*(M/G_v), \Omega_{M/G_v} - B_{\lambda_v}) \rightarrow V^* \pi_{1,v}$, with the symplectic structure modified by $B_{\lambda_v} \in \Omega^2((T^*(M/G_v)))$, the magnetic term associated with $\lambda_v$.

Moreover, $\varphi_{\lambda_v}$ is a symplectic principal $\mathbb{R}$-bundle isomorphism if and only if $g = g_v$ (in particular, if $v = 0$ or $G = G_v$), where $g_v$ is the Lie algebra of $G_v$.

**Proof.** Using the cotangent bundle reduction theory (see [1] for more details), we have that there is a symplectic embedding

$$\varphi_{\lambda_v} : (T^*M)_v \rightarrow T^*(M/G_v)$$

which is an isomorphism if and only if $g = g_v$.

Now, we will prove that $\varphi_{\lambda_v}$ is a principal $\mathbb{R}$-bundle morphism between $(\mu_{\pi_v})_v$ and $\mu_{\pi_{1,v}}$. 

13
First, we suppose that $G = G_v$. In such a case, $\varphi_{\lambda_v}$ is the symplectic isomorphism described as follows. Consider the map $\tilde{\varphi}_{\lambda_v} : J^{-1}(v) \to T^*(M/G)$ given by

$$\tilde{\varphi}_{\lambda_v}(\alpha_v(T_\pi \pi_v(v))) = (\alpha_v - \lambda_v(x))(v),$$

for all $\alpha_v \in J^{-1}(v) \cap T^*_v M$ and $v \in T M$. This map is invariant with respect to $\phi : G \times J^{-1}(v) \to J^{-1}(v)$. The corresponding quotient map from $J^{-1}(v)/G = (T^* M)_v$ to $T^*(M/G)$ is just $\varphi_{\lambda_v}$.

Now, we prove that $\tilde{\varphi}_{\lambda_v}$ is equivariant with respect to the $R$-actions $\psi_\pi : R \times J^{-1}(v) \to J^{-1}(v)$ and $\psi_{\pi_v} : R \times T^*(M/G) \to T^*(M/G)$, that is,

$$\tilde{\varphi}_{\lambda_v} \circ (\psi_\pi)_s = (\psi_{\pi_v})_s \circ \tilde{\varphi}_{\lambda_v},$$

for any $s \in R$. (4.13)

In fact, for all $\alpha_v \in J^{-1}(v) \cap T^*_v M$ and $v \in T M$,

$$[(\psi_{\pi_v})_s \circ \tilde{\varphi}_{\lambda_v}](\alpha_v(T_\pi \pi_v(v))) = (\alpha_v - \lambda_v(x))(v) + s\pi_v^*(\tilde{\eta}_s)(v),$$

where $\tilde{\eta} = (\pi_v^* s)^*(d \tau)$. From (4.11), we deduce (4.13).

If $\pi_v : J^{-1}(v) \to J^{-1}(v)/G_v$ denotes the quotient map, from (4.13) and since $\varphi_{\lambda_v} \circ \pi_v = \tilde{\varphi}_{\lambda_v}$ and $\pi_v$ is equivariant with respect to the principal $R$-actions, we have that

$$\varphi_{\lambda_v} \circ (\psi_{\pi_v})_s \circ \pi_v = \varphi_{\lambda_v} \circ \pi_v \circ (\psi_{\pi})_s \circ \tilde{\varphi}_{\lambda_v},$$

with $(\psi_{\pi})_s : R \times (T^* M)_v \to (T^* M)_v$ being the $R$-action on the reduced space $(T^* M)_v$ induced by $\pi_v$. Thus, using the fact that $\pi_v$ is surjective, we conclude that $\varphi_{\lambda_v}$ is a symplectic principal $R$-bundle morphism in the case $G = G_v$.

Finally, suppose that $v$ is an arbitrary element of $g^*_v$. Consider the action $\phi_v : G_v \times M \to M$ induced by $\phi$. Its cotangent lift $T^* \phi_v : G_v \times T^* M \to T^* M$ is a symplectic action which admits an $Ad^*$-equivariant momentum map $J_v : T^* M \to g^*_v$ given by (4.12).

If $v' = v|_{g_v} \in g_v^*$, then $v'$ is a fixed point of the coadjoint action of $G_v$, i.e. $(G_v)_v = G_v$. Moreover, the $G_v$-invariant embedding $\tilde{\iota} : J^{-1}(v) \to J^{-1}(v')$ descends to the quotient and we obtain

$$\iota : J^{-1}(v)/G_v \hookrightarrow J^{-1}(v')/G_v.$$  (4.14)

Note that $\iota$ is equivariant with respect to the $R$-actions $\psi_{\pi} : R \times J^{-1}(v) \to J^{-1}(v)$ and $\psi_{\pi_v} : R \times J^{-1}(v') \to J^{-1}(v')$. Thus, $\iota$ is equivariant with respect to the reduced $R$-actions

$$(\psi_{\pi})_v : R \times J^{-1}(v)/G_v \to J^{-1}(v)/G_v$$

and

$$(\psi_{\pi_v})_v : R \times J^{-1}(v')/G_v \to J^{-1}(v')/G_v.$$  

On the other hand, $J^{-1}(v)/G_v$ (respectively, $J^{-1}(v')/G_v$) is the total space of the reduced symplectic principal $R$-bundles $(\mu_{\pi})_v$ (respectively, $(\mu_{\pi_v})_v$) obtained from $\mu_\pi$ using the canonical action of $G$ (respectively, $G_v$) on $T^* M$. Consequently, $\iota$ is a symplectic principal $R$-bundle embedding.

Now, using that $(G_v)_v = G_v$ and the first part of the proof, we have a symplectic principal $R$-bundle isomorphism

$$\varphi_{\pi_v} : (T^* M)_v \to T^*(M/G_v)$$

between the reduced symplectic principal $R$-bundles $(\mu_{\pi})_v : ((T^* M)_v, (\Omega_M)_v) \to (V^* \pi)_v$ and $(\mu_{\pi_v})_v : (T^*(M/G_v), \Omega_{M/G_v} - B_v) \to V^* \pi_{\pi_v}$. Composing $\iota$ with $\varphi_{\pi_v}$, we obtain the required embedding $\varphi_{\lambda_v}$.  

Under the same hypotheses as in theorem 4.6, using (3.5) and (3.7), it follows that the Poisson structures on $T^*(M/G_v)$ and $V^* \pi_{\pi_v}^*$ are

$$\Lambda_{T^*(M/G_v)} + \beta_{\lambda_v}^\mu \text{ and } \Lambda_{V^* \pi_{\pi_v}^*} + \tilde{\beta}_{\lambda_v}^\mu,$$

respectively, where $\tilde{\beta}_{\lambda_v}$ is the restriction of $\beta_{\lambda_v}$ on $V^* \pi_{\pi_v}^* \times V^* \pi_{\pi_v}^*$.  

On the other hand, if \( \psi^V_\lambda \) : \((V^*\pi)_\lambda \rightarrow V^*\pi^*_1 \) is the corresponding embedding between the base spaces of the principal \( \mathbb{R} \)-bundles, \([\alpha_1] \) \in \((T^*M)_\nu\) and \([\bar{\alpha}_1] \) \in \((V^*\pi)_\nu\), then from (3.10), we have that

\[
T^*_{\psi^V_\lambda ([\alpha_1])}(T^*(M/G_\nu)) = (T^*_{[\alpha_1]}(T^*M))^o \oplus \bar{\varpi}_{\lambda}(T^*_{[\alpha_1]}(T^*M)),
\]

and the corresponding projectors

\[
q^*_{\bar{\alpha}_1} : T^*_{\psi^V_{\lambda}[\bar{\alpha}_1]}(V^*\pi^*_1) \rightarrow (T^*_{[\bar{\alpha}_1]}(V^*\pi))^o.
\]

Moreover, using proposition 3.8, we conclude that

**Theorem 4.7.** Under the same hypotheses as in theorem 4.6, the reduced Poisson structures \( \Lambda_\nu \) and \( \bar{\Lambda}_\nu \) on \((T^*M)_\nu\) and \((V^*\pi)_\nu\), respectively, are given by

\[
\Lambda_\nu([\alpha_1])(\psi^V_{\lambda_1}\alpha_1, \psi^V_{\lambda_2}\alpha_2) = (\Lambda_{T^*(M/G_\nu)} + \bar{\varpi}_{\lambda}(\psi_{\lambda}[\alpha_1]))(\alpha_1, \alpha_2)
\]

and

\[
\bar{\Lambda}_\nu([\bar{\alpha}_1])(\psi^V_{\lambda_1}\bar{\alpha}_1, \psi^V_{\lambda_2}\bar{\alpha}_2) = (\Lambda_{T^*(M/G_\nu)} + \bar{\varpi}_{\lambda}(\psi_{\lambda}[\bar{\alpha}_1]))(\bar{\alpha}_1, \bar{\alpha}_2),
\]

for all \( \alpha_1, \alpha_2 \in T^*_{\psi^V_{\lambda}[\alpha_1]}(T^*(M/G_\nu)) \), \( \alpha_1, \bar{\alpha}_2 \in T^*_{\psi^V_{\lambda}[\bar{\alpha}_1]}(V^*\pi^*_1) \) and \([\alpha_1] \in (T^*M)_\nu\), \([\bar{\alpha}_1] \in (V^*\pi)_\nu\).

**Example 4.8** (The multidimensional time-dependent damped harmonic oscillator). See [6] and references therein. This time-dependent mechanical system involves harmonic oscillators with time-dependent frequency or with time-dependent masses or subject to linear time-dependent damping forces. The configuration space is the manifold \( \mathbb{R}^2 \times \mathbb{R} \) fibered on \( \mathbb{R} \) with respect to the surjective submersion \( pr_2 : \mathbb{R}^2 \times \mathbb{R} \rightarrow \mathbb{R} \) and the corresponding restricted phase space of momenta is \( V^*pr_2 = T^*\mathbb{R}^2 \). The Hamiltonian function \( H : V^*pr_2 = T^*\mathbb{R}^2 \times \mathbb{R} \cong (\mathbb{R}^2 \times \mathbb{R}^2) \times \mathbb{R} \rightarrow \mathbb{R} \) is given by

\[
H(q^1, q^2, p_1, p_2, t) = \frac{\sigma(t)}{2}(p_1^2 + p_2^2) + F(t)((q^1)^2 + (q^2)^2)
\]

with \( \sigma, F : \mathbb{R} \rightarrow \mathbb{R} \) real \( C^\infty \)-functions on \( \mathbb{R} \).

We consider the action \( \phi : S^1 \times (\mathbb{R}^2 \times \mathbb{R}) \rightarrow (\mathbb{R}^2 \times \mathbb{R}) \) of \( S^1 \) on \( \mathbb{R}^2 \times \mathbb{R} \) given by

\[
\phi_\theta(q^1, q^2, t) = (q^1 \cos \theta + q^2 \sin \theta, -q^1 \sin \theta + q^2 \cos \theta, t), \quad \text{for } \theta \in S^1,
\]

which is not free. However, if one restricts this action to \( (\mathbb{R}^2 \setminus \{(0, 0)\}) \times \mathbb{R} \cong (S^1 \times \mathbb{R}^+) \times \mathbb{R}, \)

\( \phi \) is free and proper. Then, in order to reduce the system, we consider the second projection \( \pi : (S^1 \times \mathbb{R}^+) \times \mathbb{R} \rightarrow \mathbb{R} \) and the corresponding symplectic \( \mathbb{R} \)-principal bundle \( \mu_\pi : T^*(S^1 \times \mathbb{R}^+) \times \mathbb{R} \rightarrow T^*(S^1 \times \mathbb{R}^+) \times \mathbb{R}, \)

\( (\theta, r, p_\theta, p_r, t, p) \mapsto (\theta, r, p_\theta, p_r, t). \)

A direct computation proves that \( \pi \circ \phi_\theta = \pi \). Therefore, \( T^*\phi : S^1 \times (T^*(S^1 \times \mathbb{R}^+) \times \mathbb{R}) \rightarrow T^*(S^1 \times \mathbb{R}^+) \times \mathbb{R} \) is a canonical action. On the other hand, we have the momentum maps \( J : T^*(S^1 \times \mathbb{R}^+) \times \mathbb{R} \rightarrow \mathbb{R} \) and \( J^{V*\pi} : T^*(S^1 \times \mathbb{R}^+) \times \mathbb{R} \rightarrow \mathbb{R} \) deduced from (4.10) whose explicit expressions are

\[
J(\theta, r, p_\theta, p_r, t, p) = p_\theta, \quad J^{V*\pi}(\theta, r, p_\theta, p_r, t) = p_\theta.
\]
If \( v \in \mathbb{R} \), then the corresponding level sets may be expressed as
\[
J^{-1}(v) \cong S^1 \times T^* \mathbb{R}^+ \times \mathbb{R}^2, \quad (J^{-1})^{-1}(v) \cong S^1 \times T^* \mathbb{R}^+ \times \mathbb{R}
\]
and, since the isotropy subgroup of \( S^1 \) at \( v \) is again \( S^1 \), the reduced spaces are just
\[
J^{-1}(v)/S^1 \cong T^* (\mathbb{R}^+ \times \mathbb{R}), \quad (J^{-1})^{-1}(v)/S^1 \cong T^* \mathbb{R}^+ \times \mathbb{R}.
\]
Finally, the Poisson structure on \((J^{-1})^{-1}(v)/S^1 \cong T^* \mathbb{R}^+ \times \mathbb{R}\) is the one induced by the standard cosymplectic structure.

**Example 4.9** (The time-dependent heavy top). See [19] and references therein. This system consists of a rigid body with a fixed point moving in a time-dependent gravitational field.

The configuration space for this mechanical system is the product manifold \( SO(3) \times \mathbb{R} \) fibered on \( \mathbb{R} \) by the second projection \( \pi : SO(3) \times \mathbb{R} \rightarrow \mathbb{R} \). Moreover, the phase space of momenta \( V^* \pi \) may be identified in a natural way with \( (SO(3) \times \mathbb{R}^3) \times \mathbb{R} \) using the left trivialization of \( T^* SO(3) \). Under this identification, the Hamiltonian function \( H : (SO(3) \times \mathbb{R}) \times \mathbb{R}^3 \rightarrow \mathbb{R} \) is given by
\[
H((A, t), \Pi) = \frac{1}{2}\{I^{-1} \Pi, \Pi\} + \{A^{-1} e_3, \gamma(t)\},
\]
where \( I : so(3) \cong \mathbb{R}^3 \rightarrow so^* (3) \cong \mathbb{R}^3 \) is the inertial tensor of the body and \( \gamma : \mathbb{R} \rightarrow \mathbb{R}^3 \) is the time-dependent gravitational field.

Now, we consider the closed subgroup of \( SO(3) \),
\[
K = \begin{cases}
\begin{pmatrix}
\cos \theta & \sin \theta & 0 \\
-\sin \theta & \cos \theta & 0 \\
0 & 0 & 1
\end{pmatrix} & \theta \in \mathbb{R}
\end{cases}
\cong S^1.
\]
If \( \{e_1, e_2, e_3\} \) is the canonical basis of \( so(3) \cong \mathbb{R}^3 \), then the Lie algebra associated with \( K \) is just \((e_3)\).

In addition, we take the action of \( K \) on \( T^* (SO(3) \times \mathbb{R}) \cong (SO(3) \times \mathbb{R}) \times (\mathbb{R}^3 \times \mathbb{R}) \) given by
\[
\phi(A \theta, (A, t), \Pi, p) = ((A \theta A), t, \Pi, p),
\]
with \( A \theta \in K, A \in SO(3), t \in \mathbb{R} \) and \((\Pi, p) \in \mathbb{R}^3 \times \mathbb{R} \). This action is free and proper and \( \pi \) is invariant with respect to it.

Let \( J : (SO(3) \times \mathbb{R}) \times (\mathbb{R}^3 \times \mathbb{R}) \rightarrow \mathbb{R} \) be the momentum map deduced from (4.10) whose explicit expression is
\[
J((A, t), \Pi, p) = \lambda \Pi \cdot e_3.
\]
Now, for \( v \in \mathbb{R} \), the isotropic subgroup \( K_v \) is just \( S^1 \) and the level set \( J^{-1}(v) \) is
\[
\{(A, t), (\Pi, p)\} \in (SO(3) \times \mathbb{R}) \times (\mathbb{R}^3 \times \mathbb{R})/\lambda \Pi \cdot e_3 = v \}.
\]

If we apply the cotangent bundle reduction using the principal connection \( \lambda : T(SO(3)) \rightarrow \mathbb{R} \) given by \( \lambda(A, v) = (Av) \cdot e_3 \), we obtain that the reduced symplectic manifold \( J^{-1}(v)/K_v \) is diffeomorphic to \( T^* (S^2 \times \mathbb{R}) \cong T^* S^2 \times \mathbb{R}^2 \). The explicit diffeomorphism \( J^{-1}(v)/H_v \rightarrow T^* S^2 \times \mathbb{R}^2 \) is
\[
[(A, t), (\Pi, p)] \rightarrow \left( (A^{-1} e_3) \times \Pi, (t, p) \right).
\]
Note that \( T^*_A S^2 \cong \{ u \in \mathbb{R}^3/\mathbb{R} \cdot (A^{-1} e_3) = 0 \} \). Moreover, the symplectic 2-form on \( T^* (S^2 \times \mathbb{R}) \) is \( \Omega_{S^2 \times \mathbb{R}} = \pi_{S^2 \times \mathbb{R}}^\ast (\omega_{S^2}) \), where \( \Omega_{S^2 \times \mathbb{R}} \) is the canonical symplectic structure on \( T^* (S^2 \times \mathbb{R}) \), \( \pi_{S^2 \times \mathbb{R}} : T^* (S^2 \times \mathbb{R}) \rightarrow S^2 \times \mathbb{R} \) is the canonical projection and \( \omega_{S^2} \) is the symplectic area on \( S^2 \), i.e.
\[
\omega_{S^2} (x)(u, v) = -x \cdot (u \times v), \quad \forall x \in S^2, u, v \in T_x S^2 \subseteq T_x \mathbb{R}^3 \cong \mathbb{R}^3.
\]
Lemma 5.1. Let \( \varphi : (SO(3) \times \mathbb{R}) \times \mathbb{R}^3 \to \mathbb{R} \) be the Poisson momentum map 
\[ J^{\varphi^*} : (SO(3) \times \mathbb{R}) \times \mathbb{R}^3 \to \mathbb{R} \]
is given by
\[ J^{\varphi^*}(A, t), \Pi) = A\Pi \cdot \epsilon_3. \]
The level set \((J^{\varphi^*})^{-1}(v)\) (respectively, the reduced space \( J^{\varphi^*}(v)/K_\nu \)) is diffeomorphic to 
\((SO(3) \times \mathbb{R}) \times \mathbb{R}^2\) (respectively, to \( T^*S^2 \times \mathbb{R} \)). In order to describe the Poisson structure on 
this reduced space, we consider the symplectic 2-form \( \varphi \). The level set 
\([J^\varphi]^{-1}(v)\) is just the Poisson structure induced by \( pr^*_1(\Omega) \), where \( pr_1 : T^*S^2 \times \mathbb{R} \to T^*S^2 \) is the canonical projection on the first factor.

5. Non-autonomous Hamiltonian reduction

5.1. Non-autonomous Hamiltonian systems

In this section, we extend the example in section 2 for a symplectic principal \( \mathbb{R} \)-bundle in the presence of a Hamiltonian section. Let \( \mu : A \to V \) be a principal \( \mathbb{R} \)-bundle with principal action \( \varphi : \mathbb{R} \times A \to A \) and infinitesimal generator \( Z_\mu \).

It is well known (see [9]) that there exists a one-to-one correspondence between the space of the sections of \( \mu \) and the set \( \{ F \in \mathcal{C}^\infty(A) | Z_\mu(F) = 1 \} \). In fact, if \( h : V \to A \) is a section of \( \mu \), there is a unique function \( F_h : A \to \mathbb{R} \) such that
\[ a = \varphi(F_h(a), h(a)), \quad \text{for any } a \in A. \quad (5.1) \]
The following result will be useful in the following.

Lemma 5.1. Let \( \mu : A \to V \) be a principal \( \mathbb{R} \)-bundle with the principal action \( \varphi : \mathbb{R} \times A \to A \) and \( h : V \to A \) a section of \( \mu \). Then
\[ F_h(h(v)) = 0, \quad \text{for any } v \in V, \quad (5.2) \]
\[ F_h(\varphi(s, a)) = s + F_h(a), \quad \text{for any } s \in \mathbb{R}, \ a \in A. \quad (5.3) \]

Proof. For any \( v \in V \), we have (see (5.1))
\[ h(v) = \varphi(F_h(h(v)), h(\mu(h(v)))) = \varphi(F_h(h(v)), h(v)). \]
Thus, since \( \varphi \) is a free action, we deduce that \( F_h(h(v)) = 0 \).
Moreover, from (5.1), for any \( s \in \mathbb{R} \) and \( a \in A \),
\[ \varphi(s, a) = \varphi(F_h(\varphi(s, a)), h(\mu(\varphi(s, a)))) = \varphi(F_h(\varphi(s, a)), h(\mu(a))). \quad (5.4) \]
On the other hand, using again (5.1), it follows that
\[ \varphi(s, a) = \varphi(s, F_h(a), h(\mu(a))) = \varphi(s + F_h(a), h(\mu(a))). \quad (5.5) \]
Comparing (5.4) and (5.5), we obtain (5.3). \( \square \)

Using (5.3), we deduce that \( \varphi^* (dF_h) = dF_h \), for any \( s \in \mathbb{R} \) and since \( dF_h(Z_\mu) = 1 \), it follows that \( dF_h : TA \to \mathbb{R} \) is the connection 1-form of a principal connection on the principal
\( \mathbb{R} \)-bundle \( \mu : A \to V \) (see [9]).

The horizontal sub-bundle associated with the principal connection is
\[ a \in A \mapsto H^a_\mu = \{ X \in T_a A | X(F_h) = 0 \} \subseteq T_a A \]
and thus
\[ T_a A = H^a_\mu \oplus V_a \mu = H^a_\mu \oplus (Z_\mu(a)). \quad (5.6) \]
Note that
\[ T_{h(\mu(a))}\mu(T_{\mu(a)}h \circ T_{\mu}\mu)(X) = (T_{\mu}\mu)(X) \]
and, moreover, from (5.2)
\[ \{(T_{\mu(a)}h \circ T_{\mu}\mu)(X))(F_h) \} = 0. \]
This implies that
\[ (T_{h(\mu(a))}\psi_{F_{h(a)}})(T_{\mu(a)}h \circ T_{\mu}\mu)(X)) = X - X(F_h)Z_{\mu(a)} \]
and, therefore, the horizontal projector \( \text{hor}_a : T_a A \rightarrow H_{h a} \) is given by
\[ \text{hor}_a(X) = (T_{h(\mu(a))}\psi_{F_{h(a)}} \circ T_{\mu(a)}h \circ T_{\mu}\mu)(X). \] (5.7)

**Definition 5.2.** A non-autonomous Hamiltonian system \((A, \mu, \Omega, h)\) is a symplectic principal \(\mathbb{R}\)-bundle \(\mu : (A, \Omega) \rightarrow V\) endowed with a section \(h : V \rightarrow A\) of \(\mu\), i.e. a smooth map such that \(\mu \circ h = \text{id}_V\).

The section \(h : V \rightarrow A\) is called the Hamiltonian section of the system.

In this subsection, we prove that, given a non-autonomous Hamiltonian system \((A, \mu, \Omega, h)\), the base manifold \(V\) of the principal \(\mathbb{R}\)-bundle \(\mu\) may be equipped with a cosymplectic structure.

**Proposition 5.3.** Let \((A, \mu, \Omega, h)\) be a non-autonomous Hamiltonian system. Then the Hamiltonian vector field \(H_{F_h} \in \mathfrak{X}(A)\) of the function \(F_h\) associated with a Hamiltonian section \(h : V \rightarrow A\) is \(\mu\)-projectable to a vector field \(\mathcal{R}_h\) on \(V\).

**Proof.** Since the infinitesimal generator \(Z_\mu\) is locally Hamiltonian, for any \(a \in A\), there exists a function \(\tau\) defined on an open neighborhood \(U\) of \(a\) such that the restriction of \(Z_\mu\) on \(U\) is the Hamiltonian vector field of \(\tau\). Using the definition of \(F_h\), we have that on \(U\),
\[ \{\tau, F_h\}_A = -H_{\tau}(F_h) = -Z_\mu(F_h) = -1, \]
with \(\{\cdot, \cdot\}_A\) being the Poisson bracket on \(A\) induced by the symplectic form \(\Omega\). As a consequence,
\[ L_{Z_\mu}H_{F_h} = [H_{\tau}, H_{F_h}] = -H_{\tau|F_h}_A = 0. \]
Thus, the Lie derivative of \(H_{F_h}\) with respect to any vertical vector field is again vertical. This is a sufficient (and necessary) condition to ensure the \(\mu\)-projectability of \(H_{F_h}\).

The \(\mu\)-projection \(\mathcal{R}_h\) of \(H_{F_h}\) is a vector field on \(V\), which describes the Hamiltonian dynamics of the non-autonomous Hamiltonian system \((A, \mu, \Omega, h)\), as we will see in what follows.

**Proposition 5.4.** Let \((A, \mu, \Omega, h)\) be a non-autonomous Hamiltonian system. If \(\omega_h \in \Omega^2(V)\) and \(\eta_h \in \Omega^1(V)\) are defined by
\[ \omega_h = h^*\Omega, \quad \eta_h = -h^*(i_{Z_{\mu}}\Omega), \] (5.8)
then
\[ \Omega = \mu^*\omega_h - dF_h \wedge \mu^*\eta_h \] (5.9)
and
\[ \mu^*\eta_h = -i_{Z_{\mu}}\Omega. \] (5.10)
Proof. First of all, we will see that (5.10) holds. It is clear that
\[(\mu^*\eta_h)(Z_u) = -(i_{Z_u\Omega})(Z_u) = 0.\] (5.11)
On the other hand, from (5.7) and since \(\mu \circ \psi_s = \mu\) and \(\mu \circ h = id\), it follows that
\[(\mu^*\eta_h)(a)(\text{hor}_a^h(X)) = -[h^*(i_{Z_e\Omega})(\mu(a))(T_a\mu)(X)),\]
for \(a \in A\) and \(X \in T_aA\).

Thus, since \(\psi\) is a symplectic action, we obtain that
\[\mu^*(\eta_h)(a)(\text{hor}_a^h(X)) = -(i_{Z_e\Omega})(a)(\text{hor}_a^h(X)).\]

This, using (5.6) and (5.11), proves (5.10).

Next, we will see that (5.9) holds.
From (5.10), we deduce that
\[i_{Z_e\Omega} = i_{Z_e}(\mu^*\omega_h - dF_h \wedge \mu^*\eta_h).\] (5.12)
On the other hand, using (5.7) and (5.8) and the fact that \(\psi\) is a symplectic action, we have that
\[\Omega(a)(\text{hor}_a^h(X), \text{hor}_a^h(Y)) = (\mu^*\omega_h)(a)(X, Y)
\[= (\mu^*\omega_h)(a)(\text{hor}_a^h(X), \text{hor}_a^h(Y))
\[= (\mu^*\omega_h - dF_h \wedge \mu^*\eta_h)(\text{hor}_a^h(X), \text{hor}_a^h(Y))\] (5.13)
for \(a \in A\) and \(X, Y \in T_aA\).

Therefore, from (5.6), (5.12) and (5.13), we deduce (5.9). □

Now, we may prove the following result.

Theorem 5.5. Let \((A, \mu, \Omega, h)\) be a non-autonomous Hamiltonian system with the infinitesimal generator \(Z_\mu\). If \(\omega_h\) and \(\eta_h\) are the 1-form and the 2-form, respectively, on \(V\) defined by (5.8), then \((V, \omega_h, \eta_h)\) is a cosymplectic manifold. The Reeb vector field of the cosymplectic structure on \(V\) is just \(R_h\).

Proof. From (5.9) and (5.10) and since \(\Omega\) is closed and \(\mathcal{L}_{Z_e}\Omega = 0\), we deduce that \(\omega_h\) and \(\eta_h\) are closed.

Now, using (5.10) and proposition 5.4, we have that
\[\eta_h(R_h) = (\mu^*\eta_h)(\mathcal{H}_R) = (i_{\mathcal{H}_R}\Omega)(Z_\mu) = 1.\] (5.14)
On the other hand, from (5.9) and proposition 5.4, it follows that
\[\mu^*(i_{\mathcal{R}_\mu}\omega_h) = i_{\mathcal{R}_\mu}(\Omega + dF_h \wedge \mu^*\eta_h).\]

Thus, using (5.14), we obtain that \(\mu^*(i_{\mathcal{R}_\mu}\omega_h) = 0\) which implies that
\[i_{\mathcal{R}_\mu}\omega_h = 0.\] (5.15)
Next, suppose that \(\text{dim}A = 2n + 2\). Then, from (5.15), we deduce that \(\text{rank}(\omega_h) \leq 2n\). Therefore, using (5.4), it follows that
\[0 \neq \Omega^{n+1} = c(\mu^*\omega_h)^n \wedge dF_h \wedge \mu^*\eta_h,\] with \(c \in \mathbb{R}, c \neq 0\).

Consequently, the rank of \(\mu^*\omega_h\) is \(2n\) and we have that
\[\text{rank} \omega_h = 2n.\] (5.16)
Conditions (5.14)–(5.16) imply that \(\eta_h \wedge \omega_h^n \neq 0\). □

The cosymplectic structure \((\omega_h, \eta_h)\) on \(V\) defined on the base manifold \(V\) of a non-autonomous Hamiltonian system \((A, \mu, \Omega, h)\) induces a Poisson structure \(\{\cdot, \cdot\}_h\) on \(V\). On the other hand, as we know (see proposition 3.5), \(V\) is equipped with a Poisson structure \(\{\cdot, \cdot\}_V\) in such a way that \(\mu\) is a Poisson map. The next result shows that the Poisson brackets \(\{\cdot, \cdot\}_h\) and \(\{\cdot, \cdot\}_V\) are equal.
Proposition 5.6. Let \((A, \mu, \Omega, h)\) be a non-autonomous Hamiltonian system. \([[\cdot, \cdot]]_h\) the Poisson bracket on \(V\) associated with the cosymplectic structure \((\omega_h, \eta_h)\) and \([[\cdot, \cdot]]_V\) the Poisson bracket on \(V\) induced by the symplectic principal \(\mathbb{R}\)-bundle structure. Then, \([[\cdot, \cdot]]_h = [[\cdot, \cdot]]_V\).

Proof. Fix a real \(C^\infty\)-function \(f\) on \(V\). It is sufficient to prove that the Hamiltonian vector field \(X_f\) on \(V\) with respect to the Poisson bracket \([[\cdot, \cdot]]_V\) is equal to the Hamiltonian vector field of \(f\) with respect to the cosymplectic structure \((\omega_h, \eta_h)\). Note that, since \(\mu\) is a Poisson map, it follows that the Hamiltonian vector field \(H_{f\circ\mu} \in \mathfrak{X}(A)\) is \(\mu\)-projectable and its projection is just \(X_f\). Thus, from (5.10), we have
\[
\eta_h(X_f) = \mu^*\eta_h(H_{f\circ\mu}) = -i_{\partial V} \Omega(H_{f\circ\mu}) = \partial_t f \circ \mu = 0. \tag{5.17}
\]
On the other hand, using that \(\mathcal{R}_h\) is \(\mu\)-projectable on \(\mathcal{R}_h\), we deduce that
\[
\mathcal{R}_h(f) = \mathcal{R}_h(f \circ \mu) = -dF_h(H_{f\circ\mu}).
\]
Now, from (5.9) and (5.17), it follows that
\[
(i_X, \omega_h)(\mu(a))(T_{\partial Y} \mu) = (\mu^*\omega_h)(a)(\mathcal{H}_{f\circ\mu}(a), \tilde{Y}) = \Omega(a)(\mathcal{H}_{f\circ\mu}(a), \tilde{Y}) + (dF_h \circ \mu)(a)(\mathcal{H}_{f\circ\mu}(a), \tilde{Y}) = (df - \mathcal{R}_h(f)\eta_h)(\mu(a))(T_{\partial Y} \mu),
\]
for all \(\tilde{Y} \in T_{\partial Y} A\), with \(a \in A\). Therefore,
\[
i_X, \omega_h = df - \mathcal{R}(f)\eta_h.
\]
This ends the proof of the result. \(\square\)

In what follows, we will prove that the integral curves of the vector field \(\mathcal{R}_h\) satisfy local equations which are just the Hamilton equations. For this purpose, we will use canonical coordinates on the symplectic principal \(\mathbb{R}\)-bundle \(\mu : (A, \Omega) \to M\) (see theorem 3.4).

Let \((t, p, q', p_1)\) be the canonical coordinates on \(A\). Suppose that the local expression of the Hamiltonian section \(h: V \to A\) is
\[
h(t, q', p_1) = (t, -H(t, q', p_1), q', p_1),
\]
where \(H\) is a local function on \(V\). Then, \(F_h: A \to \mathbb{R}\) may be described locally by
\[
F_h(t, p, q', p_1) = p + H(t, q', p_1).
\]
Since \((t, p, q', p_1)\) are the Darboux coordinates for the symplectic form \(\Omega\) on \(A\), we have that
\[
\mathcal{H}_h = \frac{\partial}{\partial t} - H \frac{\partial}{\partial p} + \frac{\partial H}{\partial p_1} \frac{\partial}{\partial q'} - \frac{\partial H}{\partial p} \frac{\partial}{\partial p_1}, \quad \mathcal{R}_h = \frac{\partial}{\partial t} + H \frac{\partial}{\partial p_1} - \frac{\partial H}{\partial q'} \frac{\partial}{\partial p_1}.
\]
Finally, the cosymplectic structure \((\omega_h, \eta_h)\) on \(V\) is locally described by
\[
\omega_h = -\frac{\partial H}{\partial q'} dt \wedge dq' - \frac{\partial H}{\partial p_1} dt \wedge dp_1 + dq' \wedge dp_1, \quad \eta_h = dt.
\]
Thus, a curve on \(V\) with the local expression
\[
t \mapsto (t, q(t), p_1(t))
\]
is an integral curve of \(\mathcal{R}_h\) if and only if it satisfies the Hamilton equations
\[
\frac{dq'}{dt} = \frac{\partial H}{\partial p_1}, \quad \frac{dp_1}{dt} = -\frac{\partial H}{\partial q'}.
\]
Therefore, in the particular case when \(\mu\) is the standard principal \(\mathbb{R}\)-bundle associated with a fibration \(\pi: M \to \mathbb{R}\), we recover the results in section 2.
5.2. Non-autonomous reduction theorem

In this subsection, we obtain a reduction theorem for non-autonomous Hamiltonian systems.

Let \( \mu : (A, \Omega) \to V \) be a symplectic principal \( \mathbb{R} \)-bundle with the infinitesimal generator \( Z_\mu \) and \( \phi : G \times A \to A \) a canonical action of a Lie group \( G \) on the symplectic principal \( \mathbb{R} \)-bundle \( \mu : (A, \Omega) \to V \). Denote by \( \phi^V : G \times V \to V \) the corresponding action on \( V \).

Now suppose that \( h : V \to A \) is a Hamiltonian section of \( \mu \).

**Definition 5.7.** The Hamiltonian section \( h \) is said to be \( G \)-equivariant if \( h \) is equivariant with respect to the actions \( \phi \) and \( \phi^V \), that is,

\[
    h \circ \phi^V_g = \phi_g \circ h, \quad \text{for } g \in G.
\]

Note that, if \( h : V \to A \) is a Hamiltonian section of a principal \( \mathbb{R} \)-bundle, then, from (4.4) and (5.1), we have that

\[
    \phi_g(a) = \psi(F_h(\phi_g(a)), h(\phi^V_g(\mu(a))))
\]

for any \( a \in A \) and \( g \in G \). On the other hand, applying \( \phi_g \) to the two sides of (5.1) and using (4.1), we obtain

\[
    \phi_g(a) = \psi(F_h(\phi_g(a)), \phi(g(\mu(a))))
\]

Comparing (5.19) and (5.20), one may deduce that a Hamiltonian section \( h : V \to A \) is \( G \)-equivariant if and only if the corresponding function \( F_h \) is \( G \)-invariant, i.e. \( F_h \circ \phi_g = F_h \) for any \( g \in G \).

**Proposition 5.8.** If \( h : V \to A \) is a \( G \)-equivariant Hamiltonian section, the induced action \( \phi^V : G \times V \to V \) is a cosymplectic action with respect to the symplectic structure \((\omega_h, \eta_h)\) on \( V \) defined by \( h \).

Moreover, if \( J : A \to g^* \) is a momentum map with respect to the action \( \phi \), then the induced momentum map \( J^V : V \to g^* \) is such that \( \mathcal{R}_h(J^V) = 0 \), for any \( \xi \in g \).

**Proof.** From the equivariance of \( h \) and the \( G \)-invariance of \( \Omega \) and \( i_\xi \Omega \), we have that \( \phi^V_g \) preserves the forms \( \omega_h \) and \( \eta_h \), for any \( g \in G \). Thus, \( \phi^V \) is a cosymplectic action. Moreover, for any \( \xi \in g \), we have (see (4.5))

\[
    \mathcal{R}_h(J^V_\xi) = \mathcal{H}_{F_h}(J^V_\xi \circ \mu) = \mathcal{H}_{F_h}(J_\xi) = -\mathcal{H}_{F_h}(F_h) = -\xi_A(F_h) = 0,
\]

with \( \xi_A \) being the infinitesimal generator of \( \phi \) defined by \( \xi \). The last equality follows from the \( G \)-invariance of \( F_h \).

Now, we may reduce the non-autonomous Hamiltonian system. Let \( (A, \mu, \Omega, h) \) be a non-autonomous Hamiltonian system equipped with a canonical action \( \phi : G \times A \to A \) of a Lie group \( G \) on the manifold \( A \) with an \( \text{Ad}^* \)-equivariant momentum map \( J : A \to g^* \). Suppose that the induced action \( \phi^V : G \times V \to V \) on \( V \) is free and proper. Let \( \nu \) be an element of \( g^* \). Then we induce a free and proper action \( \phi^V : G \times (J^V)^{-1}(\nu) \to (J^V)^{-1}(\nu) \) of \( G \) on \( (J^V)^{-1}(\nu) \) and we may apply Albert’s theorem (see theorem A.3 in the appendix). Thus, we may reduce the cosymplectic manifold \( (V, (\omega_h)_*, (\eta_h)_*) \) for obtaining a reduced cosymplectic manifold \( (V, (\omega_h)_*, (\eta_h)_*) \), where \( V \) is the quotient manifold \( (J^V)^{-1}(\nu) / G \), and \( (\omega_h)_*, (\eta_h)_* \) are the 2-form and 1-form on \( V \) characterized by

\[
    (\pi^V_\nu)^*(\omega_h)_* = (i^V_\nu)^*\omega_h, \quad (\pi^V_\nu)^*(\eta_h)_* = (i^V_\nu)^*\eta_h
\]

with \( \pi^V_\nu : (J^V)^{-1}(\nu) \to V \) and \( i^V_\nu : (J^V)^{-1}(\nu) \leftrightarrow V \) being the canonical projection and the canonical inclusion, respectively.
On the other hand, from theorem 4.3, we obtain a symplectic principal \( \mathbb{R} \)-bundle \( \mu_v : (A_v, \Omega_v) \to V_v \) with the infinitesimal generator \( Z_{\mu_v} \). We recall that the restriction of \( Z_{\mu_v} \) on \( J^{-1}(v) \) is tangent to \( J^{-1}(v) \) and that \( Z_{\mu_v}|_{J^{-1}(v)} \) is \( \pi_v \)-projectable on \( Z_{\mu_v} \). Moreover, using (4.5) and (5.18), we have that \( h \) restricts to a \( G_v \)-invariant map \( h : (J^v)^{-1}(v) \to J^{-1}(v) \).

Therefore, \( h \) induces a smooth map \( h_v : V_v \to A_v \) characterized by

\[
h_v \circ \pi^v = \pi_v \circ h. \tag{5.22}
\]

The function \( h_v \) is a section of \( \mu_v \), so \( h_v \) is a Hamiltonian section of the symplectic principal \( \mathbb{R} \)-bundle \( \mu_v : A_v \to V_v \) and \( (A_v, \mu_v, \Omega_v, h_v) \) is a non-autonomous Hamiltonian system.

A direct computation, using (4.7), (4.8), (5.1) and (5.22), shows that the function \( F_{h_v} \) on \( A_v = J^{-1}(v)/G_v \) is characterized by the following condition:

\[
F_{h_v} \circ \pi_v = F_{h|_{J^{-1}(v)}}. \tag{5.23}
\]

Thus, \( F_{h_v} \) may be obtained from \( F_h \) by passing to quotient.

Moreover, from theorem 5.5, \( (V_v, (\omega_v)_{h_v}, (\eta_v)_{h_v}) \) is a cosymplectic manifold whose structure is given by

\[
(\omega_v)_{h_v} = h_v^*\Omega_v, \quad (\eta_v)_{h_v} = -h_v^*(iz_{\mu_v} \Omega_v). \tag{5.24}
\]

**Theorem 5.9.** Let \( (A, \mu, \Omega, h) \) be a non-autonomous Hamiltonian system and \( \phi : G \times A \to A \) be a canonical action of \( G \) on \( A \) such that the induced action on \( V \) is free and proper. Suppose that \( J : A \to g^* \) is an Ad*-equivariant momentum map. If \( h \) is \( G \)-equivariant, then, for any \( v \in g^* \), the cosymplectic structure \( (\omega_v)_{h_v}, (\eta_v)_{h_v} \) on \( V \) induced by the reduced non-autonomous Hamiltonian system \( (A_v, \mu_v, \Omega_v, h_v) \) is the one deduced from Albert’s reduction of the cosymplectic structure \( (\omega_v, \eta_v) \) on \( V \). In other words,

\[
(\omega_v)_{h_v} = (\omega_v)_h, \quad (\eta_v)_{h_v} = (\eta_v)_h. \tag{5.25}
\]

In particular, the dynamics \( \mathcal{R}_h \) of the reduced non-autonomous Hamiltonian system is just the \( \pi^v \)-projection of the restriction on \( (J^v)^{-1}(v) \) of the dynamics \( \mathcal{R}_h \) of \( (A, \mu, \Omega, h) \). More precisely,

\[
\mathcal{R}_{h_v}(\pi^v(\nu)) = T_v\pi^v(\mathcal{R}_h(\nu)), \quad \text{for any } v \in (J^v)^{-1}(v). \tag{5.26}
\]

**Proof.** In order to show (5.25), we will prove that the 2-form \( (\omega_v)_{h_v} \) and the 1-form \( (\eta_v)_{h_v} \) satisfy condition (5.21). In fact, if \( v \in (J^v)^{-1}(v) \) and \( X, Y \in T_v((J^v)^{-1}(v)) \), then, using (5.22) and (5.24), we have that \( \left( (\pi^v)^*(\omega_v)_{h_v} \right)(v)(X, Y) = (\omega_v)_{h_v}(\pi^v(v))(T_v\pi^v(X), T_v\pi^v(Y)) = \Omega_v(\pi_v(h(v)))(T_h(h(X)), T_h(h(Y))) = (i_{T_v(h)}(h(v)))(T_h(h(X)), T_h(h(Y)) = (T_v\omega)(v)(X, Y). \)

Thus, \( (\pi^v)^*(\omega_v)_{h_v} = i_{T_v(h)}\omega_v \). Moreover, using again (5.22) and (5.24), we deduce that \( \left( (\pi^v)^*(\eta_v)_{h_v} \right)(v)(X) = -(h_v^*(iz_{\mu_v}(\omega_v)))(\pi^v(v))(T_v\pi^v(X)) = -(i_{T_v(h)}(\omega_v)(h(v)))(T_h(h(X))) \)

Therefore, \( (\pi^v)^*(\eta_v)_{h_v} = i_{T_v(h)}\eta_v \). \( \square \)

Note that another way to obtain (5.26) is to use (5.23). In fact, since \( \mathcal{H}_{F_h} \) (respectively, \( \mathcal{H}_{F_{h_v}} \)) is \( \mu \)-projectable (respectively, \( \mu_v \)-projectable) on \( \mathcal{R}_h \) (respectively, \( \mathcal{R}_{h_v} \)), using (A.2), we have that

\[
\mathcal{R}_{h_v}(\pi^v(\nu)) = T_{\pi_v(\nu)}\mathcal{H}_{F_{h_v}}(\pi_v(\nu)) = T_{\pi_v(\nu)}\mu_v(T_{\pi_v}h(\mathcal{H}_{F_{h_v}}(\nu))) = T_{\pi_v(\nu)}\mu_v(T_{\mu_v}\mathcal{H}_{F_{h}}(\nu)) = T_{\mu_v}\pi^v(\mathcal{R}_h(\nu)),
\]

for any \( v = \mu(a) \in (J^v)^{-1}(v) \).
Example 5.10 (The bidimensional time-dependent damped harmonic oscillator). Using the same notation as in example 4.8, we have that the extended Hamiltonian function $F_h : T^* (S^1 \times \mathbb{R}^3) \times \mathbb{R}^2 \rightarrow \mathbb{R}$ is given by

$$F_h (\theta, r, p_\theta, p_r, t, p) = \frac{\epsilon (\nu)}{2} \left( \frac{p_r^2}{r^2} + \frac{1}{r^2} p_\theta^2 + F(t)r^2 + p. \right)$$

Since $F_h$ is $T^* \phi$-invariant, we may reduce the non-autonomous Hamiltonian system $(T^* (S^1 \times \mathbb{R}^3) \times \mathbb{R}^2, \mu_\varphi, \Omega, h)$ at $v \in \mathbb{R}$. The reduced homogeneous Hamiltonian system $\tilde{F}_{h_\nu} : T^* (\mathbb{R}^3 \times \mathbb{R}) \rightarrow \mathbb{R}$ is given by

$$\tilde{F}_{h_\nu} ((\omega, \eta)) = \frac{\epsilon (\nu)}{2} \left( \frac{p_r^2}{r^2} + \frac{1}{r^2} p_\theta^2 + F(t)r^2 + \eta. \right)$$

Finally, the reduced dynamics is described by the cosymplectic structure $((\omega_\nu), (\eta_\nu))$ and the vector field $\mathcal{R}_{h_\nu}$ on $T^* \mathbb{R}^3 \times \mathbb{R}$.

$$\omega_\nu = dr \wedge dp_r + \left( 2F(t)r - \epsilon (\nu) \frac{\nu^2}{r^2} \right) dr \wedge dt + \epsilon (\nu) p_r dp_r \wedge dt, \ \ \eta_\nu = dt, \ \ \mathcal{R}_{h_\nu} = \nabla \frac{\partial}{\partial \nu} + \epsilon (\nu) p_r \frac{\partial}{\partial t} + \left( \frac{\epsilon (\nu) \nu^2}{r^2} - 2F(t)r \right) \frac{\partial}{\partial p_r}.$$

Example 5.11 (The time-dependent heavy top). Using the same notation as in example 4.9, we have that the extended Hamiltonian homogeneous function $F_h : (SO(3) \times \mathbb{R}) \times (\mathbb{R}^3 \times \mathbb{R}) \rightarrow \mathbb{R}$ associated with this system is

$$F_h ((A, \Pi, p) = \frac{1}{2} \langle I^{-1} \Pi, \Pi \rangle + \langle A^{-1} e_3, \gamma (t) \rangle + p.$$

When one applies the reduction process at the level $v = 0$, we obtain the reduced Hamiltonian homogenous function $F_{h_\nu} : T^* S^2 \times \mathbb{R}^3 \rightarrow \mathbb{R}$ which is the restriction on $T^* S^2 \times \mathbb{R}^3$ of $\tilde{F}_{h_\nu} : \mathbb{R}^3 \times S^2 \times \mathbb{R}^3 \rightarrow \mathbb{R}$,

$$\tilde{F}_{h_\nu} ((q, p_q, t, p)) = \frac{1}{2} \langle I^{-1} (p_q \times q), (p_q \times q) \rangle + \langle q, \gamma (t) \rangle + p.$$

In fact, the equations defining $T^* S^2$ as a submanifold of $T^* \mathbb{R}^3 \equiv \mathbb{R}^3 \times \mathbb{R}^3$ are $||q||^2 - 1 = 0$ and $q \cdot p_q = 0$. So any extension of $F_{h_\nu}$ has the form

$$\tilde{F}_{h_\nu} (q, p_q, t, p) = \tilde{F}_{h_\nu} ((q, p_q, t), p) + \lambda (q \cdot p_q) + \mu (||q||^2 - 1),$$

where $\lambda$ and $\mu$ are the Lagrange multipliers which we must determine. Then the Hamilton equations for this Hamiltonian function with an initial condition on $T^* S^2 \times \mathbb{R}$ are

$$\begin{aligned}
\dot{q} &= q \times I^{-1} (p_q \times q) + \lambda q \\
\dot{p}_q &= p_q \times I^{-1} (p_q \times q) - \gamma (t) - \lambda p_q - 2\mu q \\
\dot{t} &= 1
\end{aligned}$$

with $(q, p_q) \in T^* S^2$. Since $q \cdot \dot{q} = 0$ and $p_q \cdot \dot{p}_q + p_q \cdot q = 0$,

$$\begin{aligned}
\dot{q} &= q \times I^{-1} (p_q \times q) \\
\dot{p}_q &= p_q \times I^{-1} (p_q \times q) - \gamma (t) - \langle q, \gamma (t) \rangle q \\
\dot{t} &= 1
\end{aligned}$$

The solutions of these equations are just the integral curves of the Reeb vector field associated with the cosymplectic manifold $T^* S^2 \times \mathbb{R}$ equipped with the cosymplectic structure $(\Omega_{S^2} + dH_0 \wedge dt, dt)$ on $T^* S^2 \times \mathbb{R}$, where $H_0 : T^* S^2 \times \mathbb{R} \rightarrow \mathbb{R}$ is given by

$$H_0 (q, p_q, t) = \frac{1}{2} [t^{-1} (p_q \times q), p_q \times q] + \langle q, \gamma (t) \rangle.$$
Note that if $I = Id$ and $y(t) = 0$, then the corresponding reduced Hamilton equations are

$$\dot{q} = p_q, \quad p_q = -\|\dot{q}\|^2 q, \quad i = 1$$

or equivalently $q = -\|\dot{q}\|^2 q$ and $i = 1$. Therefore, the geodesics of the standard metric of $S^2 \times \mathbb{R}$ are just the solutions of the previous equations.

6. Another example: the frame-independent formulation of the analytical mechanics in a Newtonian spacetime

The *Newtonian spacetime* is a system $(E, \tau, g)$ where $E$ is an affine space modeled over the $n$-dimensional vector space $V$, $\tau$ is a non-zero element of $V^*$ and $g : V_0 \rightarrow V_0^*$ is a scalar product on $V_0 = \ker \tau$. Let $V_1$ be the affine subspace of $V$ defined by the equation $\tau(v) = 1$.

An element $u$ of $V_1$ may be interpreted as the family of inertial observers that move in the spacetime with the constant velocity $u$ (see [12]). We will denote by $i : V_0 \rightarrow V$ the inclusion and by $g' = i \circ g^{-1} \circ i^* : V^* \rightarrow V$ the contravariant tensor on $V$ defined by $g$.

If $u$ is a fixed inertial frame, the homogeneous Hamiltonian function on $T^*E \cong E \times V^*$ is given by

$$H_u(x, \alpha) = \alpha(u) + \frac{1}{2m} \alpha(g'(\alpha)) + \varphi(x), \quad \text{for any } x \in E, \alpha \in V^*,$$

where $\varphi : E \rightarrow \mathbb{R}$ is the potential. The aim of this section is to describe a frame-independent formulation of the dynamics and describe how a reduction procedure may be applied in the symplectic principal $\mathbb{R}$-bundle setting.

Consider the following equivalence relations on $V_1 \times E \times V^*$ and $V_1 \times E \times V_0^*$, respectively:

$$(u, x, \alpha) \sim (u', x', \alpha') \iff x = x' \text{ and } \alpha' = \alpha + \sigma(u, u')$$

$$(u, x, \alpha) \sim_0 (u', x', \alpha') \iff x = x' \text{ and } \alpha' = \alpha + mg(u - u'),$$

for any $(u, x, \alpha), (u', x', \alpha') \in V_1 \times E \times V^*$ and $(u, x, \alpha), (u', x', \alpha') \in V_1 \times E \times V_0^*$, where $\sigma : V_1 \times V_1 \rightarrow V^*$ is the map defined by

$$\sigma(u, u')(v) = g(u - u') \left( v - \tau(v) \frac{u + u'}{2} \right), \quad v \in V.$$

Then, one may easily prove that the quotient space $P = (V_1 \times E \times V^*)/\sim$ is an affine bundle over $E$ modeled over the vector bundle $E \times V^* \rightarrow E$. Moreover, if $u \in V_1$ is fixed, there exists a unique symplectic form $\Omega$ on $P$ such that the map $\Theta_u : T^*E \cong E \times V^* \rightarrow P$ given by $\Theta_u(x, \alpha) = [(u, x, \alpha)]$ is a symplectomorphism, where $E \times V^* \cong T^*E$ is equipped with the canonical symplectic 2-form. If $u' \in V_1$, then, since $\Theta^{-1}_u \circ \Theta_u : T^*E \rightarrow T^*E$ is just the translation by the constant 1-form $\sigma(u', u)\Omega$ does not depend on the choice of $u$. On the other hand, we may consider the action $\psi : \mathbb{R} \times P \rightarrow P$ and the projection $\mu : P \rightarrow P_0$ given by

$$\psi(s, [u, x, \alpha]) = [u, x, \alpha + s\tau], \quad \mu[u, x, \alpha] = [u, x, \alpha_{\|u\|}],$$

where $P_0$ is the quotient space $(V_1 \times E \times V_0^*)/\sim_0$. Then, $\mu : (P, \Omega) \rightarrow P_0$ is a symplectic principal $\mathbb{R}$-bundle and the principal action of $\mathbb{R}$ on $P$ is just $\psi$.

Consider the following Hamiltonian section $h : P_0 \rightarrow P$:

$$h[u, x, \alpha] = \left[ u, x, \alpha \circ i_u - \left( \frac{1}{2m} \alpha(g^{-1}(\alpha)) + \varphi(x) \right) \tau \right],$$

where $i_u : V \rightarrow V_0$ is the projection $v \mapsto v - \tau(v)u$. Note that the corresponding function $F_h : P \rightarrow \mathbb{R}$ is just the homogeneous Hamiltonian function, that is, $F_h[u, x, \alpha] = H_u(x, \alpha)$. Thus, $(P, \mu, \Omega, h)$ is a non-autonomous Hamiltonian system (frame-independent dynamical system in a Newtonian spacetime).
Now we will introduce a symmetry in the system: let $G$ be a subgroup of the group of the affine transformation of $A$. Suppose that for any $f_L \in G$, where $L : V \to V$ is the corresponding linear map, we have that
\[ L^* \tau = \tau, \quad L_{\mu} \text{ preserves } g \text{ and } \varphi \circ f_L = \varphi. \]
Moreover, we will suppose that $g \subset Aff(E, V_0)$. Then, we may consider the action $\phi : G \times P \to P$ defined by
\[ (f_L, [u, x, \alpha]) \mapsto \left[ Lu, f_L(x), (L^{-1})^* \alpha \right]. \]
A straightforward computation shows that $\phi$ is a canonical action on the symplectic principal $\mathbb{R}$-bundle $\mu$. Finally, we will suppose that the induced action $\phi^\mathbb{R} : G \times P_0 \to P_0$ is free and proper. If not, one may restrict to a subset of $E$ (supposed open) and repeat the proofs. For any reference frame $u \in V_1$, one may consider the momentum map $J_a : P \to g^*$ defined by
\[ J_a([w, x, \alpha]) = (\alpha - m \sigma(u, w)(\xi E(x)), \quad \text{for any } [w, x, \alpha] \in P \text{ and } \xi \in g, \]
where $\xi E \in \mathcal{X}(E)$ is the infinitesimal generator of the natural action of $G$ on $E$ and we are identifying $T_E \simeq V$. Then, one can obtain the following result.

**Theorem 6.1.** Under the previous hypotheses, if $v \in g^*$ and $u \in V_1$ are fixed, a reduced symplectic principal $\mathbb{R}$-bundle $\mu_v : (P_v, \Omega_v) \to (P_0)_v$ and a reduced Hamiltonian section $h_v : (P_0)_v \to P_0$ are given, where

\[ P_v = J^\mathbb{R}_v^{-1}(v)/G_v, \quad (P_0)_v = (J^\mathbb{R}_0)^{-1}(v)/G_v. \]

Here, $J^\mathbb{R}_0 : P_0 \to g^*$ is the momentum map for the Poisson action of $G$ on $P_0 = (V_1 \times E \times V_0^\mathbb{R})/ \sim_0$.

### 7. Conclusions and future work

A reduction process for a symplectic principal $\mathbb{R}$-bundle is described in this paper. In particular, we discuss the case of the standard symplectic principal $\mathbb{R}$-bundle associated with a fibration over the real line. Finally, we consider the reduction of a non-autonomous Hamiltonian section on a symplectic principal $\mathbb{R}$-bundle. In order to do this, we have obtained previously a cosymplectic structure on the base space of the principal $\mathbb{R}$-bundle.

In the paper, we assume the regularity of the canonical action on the symplectic principal $\mathbb{R}$-bundle. Then one may ask if a similar construction holds if we relax this assumption in order to include other examples (see, for instance, example 4.8). We expect that well-known methods on singular reduction (see [3, 5, 24–26]) could be applied in the time-dependent setting. We remark that this reduction process could not be functorial, in the sense that a more general object (as, for instance, a suitable map between stratified spaces) could be needed.

Moreover, it would be interesting to develop the procedure of the reconstruction in the symplectic principal $\mathbb{R}$-bundle framework. The aim is to obtain the dynamics of a symmetric non-autonomous Hamiltonian system on a symplectic principal $\mathbb{R}$-bundle from the reduced dynamics. Classical techniques on symplectic reconstruction (see [21]) could be used.

On the other hand, suppose that a canonical action of a connected Lie group $G$ on a symplectic principal $\mathbb{R}$-bundle is given and that $G$ has a closed normal subgroup $H$. A goal could be to realize the reduced principal $\mathbb{R}$-bundle in a two-step procedure: first reducing by $H$ and then by an appropriate Lie group which is related to the quotient group $G/H$. It would be interesting to discuss this procedure which is called *reduction by stages* (for reduction by stages in the symplectic framework, see [20]).
Acknowledgments

The research has been partially supported by MEC (Spain) grants MTM2009-13383, MTM2010-12116-E, and the Projects of the Canary government SOLSUBC200801000238 and ProdID20100210. The authors would like to thank the referees for their very valuable comments and suggestions which have improved the paper. IL would like to thank the University of Bari and, in particular, Professor Pastore for the support.

Appendix. Poisson reduction theorems

In this appendix, we recall some well-known results about Poisson reduction in the presence of a momentum map (for more details, see [1, 2, 16, 17, 20, 22, 23, 25]).

Let \( \phi : G \times M \rightarrow M \) be an action of a Lie group \( G \) on a Poisson manifold \( (M, \{\cdot, \cdot\}) \). The action \( \phi \) is said to be a Poisson action if \( \phi_g : M \rightarrow M \) is a Poisson map for any \( g \in G \). In such a case, a smooth map \( J : M \rightarrow g^* \) from \( M \) to the dual space \( g^* \) of the Lie algebra \( g \) of \( G \) is said to be a momentum map if the infinitesimal generator \( \xi_M \) of the action associated with any \( \xi \in g \) is the Hamiltonian vector field of the function \( J_\xi : M \rightarrow \mathbb{R} \) defined by the natural pointwise pairing. Moreover, \( J \) is said to be Ad\(^*\)-equivariant if it is equivariant with respect to the action \( \phi \) and to the coadjoint action Ad\(^*\) : \( G \times g^* \rightarrow g^* \), i.e.

\[
J(\phi_g(x)) = \text{Ad}_{g^{-1}}^*(J(x)), \quad \text{for any } x \in M.
\]

If \( v \) is a regular value of \( J \), then \( J^{-1}(v) \) is a closed submanifold of \( M \). Moreover, if \( G_v \) denotes the isotropy group of \( v \) with respect to the coadjoint action, i.e.

\[ G_v = \{ g \in G : \text{Ad}^*_v(g) = v \}, \]

then \( \phi \) induces an action

\[ \phi : G_v \times J^{-1}(v) \rightarrow J^{-1}(v) \]

of \( G_v \) on the submanifold \( J^{-1}(v) \).

In addition, we have the following result.

**Theorem A.1** (Poisson reduction theorem [23]). Let \( \phi : G \times M \rightarrow M \) be a free and proper Poisson action of a Lie group \( G \) on a Poisson manifold \( (M, \{\cdot, \cdot\}) \). If \( J : M \rightarrow g^* \) is an Ad\(^*\)-equivariant momentum map associated with \( \phi \) and \( v \in g^* \) is a regular value of \( J \), then the reduced space \( M_v = J^{-1}(v)/G_v \) is a Poisson manifold with the Poisson bracket \( \{\cdot, \cdot\}_v \), characterized by

\[
\{\rho_v, \tau_v\}_v(\pi_v(x)) = \{\rho, \tau\}(x), \quad \text{for any } \rho_v, \tau_v \in C^\infty(M_v),
\]

where \( \pi_v : J^{-1}(v) \rightarrow M_v \) is the canonical projection and \( \rho, \tau \in C^\infty(M) \) are the arbitrary \( G \)-invariant extensions of \( \rho_v \circ \pi_v \) and \( \tau_v \circ \pi_v \), respectively.

Note that, if \( \rho \) is a \( G \)-invariant function on \( M \) and \( \rho_v \) is the function on \( M_v \) such that \( \rho_v \circ \pi_v = \rho|_{J^{-1}(v)} \), then the restriction on \( J^{-1}(v) \) of \( \mathcal{H}_\rho \) is tangent to \( J^{-1}(v) \) and

\[
T_x\pi_v(\mathcal{H}_\rho(x)) = \mathcal{H}_{\rho_v}(\pi_v(x)), \quad \text{for all } x \in J^{-1}(v).
\]

The symplectic version of the Poisson reduction theorem is the well-known Marsden–Weinstein reduction theorem. In this case, we will assume that the Poisson action is symplectic.
Let $\phi : G \times M \to M$ be an action of a Lie group $G$ on a symplectic manifold $(M, \Omega)$. The action $\phi$ is said to be symplectic if $\phi_g : M \to M$ is a symplectic map for any $g \in G$. If $v \in g^*$, then it is a regular value of $J$ (see for example [21], pp 8–9).

Theorem A.2 (Marsden–Weinstein reduction theorem [24]). Let $\phi : G \times M \to M$ be a free and proper symplectic action of a Lie group $G$ on a symplectic manifold $(M, \Omega)$. If $J : M \to g^*$ is an $\Ad^*$-equivariant momentum map associated with $\phi$ and $v \in g^*$, then $M_v = J^{-1}(v)/G_v$ is a symplectic manifold with symplectic 2-form $\Omega_v$ characterized by

$$\pi_v^*\Omega_v = i_v^*\Omega,$$

where $\pi_v : J^{-1}(v) \to M_v$ is the canonical projection and $i_v : J^{-1}(v) \hookrightarrow M$ is the canonical inclusion.

In fact, the Poisson structure associated with $\Omega_v$ is just the reduced Poisson structure obtained by theorem A.1 (see [22]).

Other interesting examples of Poisson manifolds are the cosymplectic manifolds. For these types of structures, Albert [2] obtained a cosymplectic reduction theorem. We recall that a cosymplectic structure on a manifold $M$ of odd dimension $2n+1$ is a couple $(\omega, \eta)$, where $\omega$ is a closed 2-form on $M$ and $\eta$ is a closed 1-form on $M$ such that $\eta \wedge \omega^2$ is a volume form. If $(\omega, \eta)$ is a cosymplectic structure on a manifold $M$, then there exists a unique vector field $R$ on $M$, the Reeb vector field, satisfying the conditions $i_R \omega = 0$ and $i_R \eta = 1$. On the other hand, the Hamiltonian vector field $\mathcal{H}_\tau$ associated with a function $\tau : M \to \mathbb{R}$ is characterized by

$$i_{\mathcal{H}_\tau} \omega = d\tau - R(\tau) \eta, \quad \eta(\mathcal{H}_\tau) = 0. \quad (A.3)$$

An action $\phi : G \times M \to M$ of a Lie group $G$ on a cosymplectic manifold $(M, \omega, \eta)$ is said to be cosymplectic if $\phi_g : M \to M$ preserves the cosymplectic structure, for any $g \in G$.

Theorem A.3 (Cosymplectic reduction theorem [2]). Let $\phi : G \times M \to M$ be a free, proper and cosymplectic action of a Lie group $G$ on a cosymplectic manifold $(M, \omega, \eta)$. Suppose that $J : M \to g^*$ is an $\Ad^*$-equivariant momentum map associated with $\phi$ such that $R(J_\xi) = 0$ for any $\xi \in g$, where $R$ is the Reeb vector field of $M$.

Then, for any $v \in g^*$, $M_v = J^{-1}(v)/G_v$ is a cosymplectic manifold with the cosymplectic structure $(\omega_v, \eta_v)$ characterized by

$$\pi_v^*\omega_v = i_v^*\omega, \quad \pi_v^*\eta_v = i_v^*\eta, \quad (A.4)$$

where $\pi_v : J^{-1}(v) \to M_v$ is the canonical projection and $i_v : J^{-1}(v) \hookrightarrow M$ is the canonical inclusion.

Moreover, the restriction $\mathcal{R}_{|J^{-1}(v)}$ of $\mathcal{R}$ is tangent to $J^{-1}(v)$ and $\pi_v$-projectable on the Reeb vector field $\mathcal{R}_\nu$ of $M_v$.

We remark that, in the hypotheses of the previous theorem, one may prove that $v$ is regular values of $J$. Furthermore, using (A.3), it is easy to show that, if $\rho$ is a $G$-invariant function on $M$ and $\rho_v$ is the function on $M_v$ such that $\rho \circ \pi_v = \rho_{J^{-1}(v)}$, then the restriction on $J^{-1}(v)$ of $\mathcal{H}_\rho$ is tangent to $J^{-1}(v)$ and $T_v \pi_v(\mathcal{H}_\rho(x)) = \mathcal{H}_{\rho_v}(\pi_v(x))$, for all $x \in J^{-1}(v)$. \quad (A.5)

This relation is formally the same as (A.2). This fact suggests that the Poisson bracket induced by the reduced cosymplectic structure is just the reduced Poisson bracket. In fact, as in the symplectic case, we have the following result.
Proposition A.4. Under the same hypotheses as in theorem A.3, the Poisson bracket associated with $(\omega_\nu, \eta_\nu)$ is just the reduced Poisson bracket $\{\cdot, \cdot\}_\nu$ deduced from theorem A.1.

Proof. Denote by $\{\cdot, \cdot\}_\nu$ (respectively, $\{\cdot, \cdot\}'_\nu$) the Poisson bracket on $M_\nu$ obtained from theorem A.1 by reducing the Poisson bracket $\{\cdot, \cdot\}$ on $M$ (respectively, induced by the reduced cosymplectic structure $(\omega_\nu, \eta_\nu)$). Let $\rho_\nu, \tau_\nu \in C^\infty(M_\nu)$, and $\rho$ and $\tau$ be the arbitrary $G$-invariant extensions of $\rho_\nu \circ \pi_\nu$ and $\tau_\nu \circ \pi_\nu$, respectively. Then, for any $x \in J^{-1}(\nu)$, using (A.1) and (A.5), we have that

$$\{\rho_\nu, \tau_\nu\}(\pi_\nu(x)) = \{\rho, \tau\}(x) = H_\tau(x)(\rho_\nu \circ \pi_\nu(x)) = \{\rho_\nu, \tau_\nu\}'_\nu(\pi_\nu(x)).$$

Since $\pi_\nu$ is surjective, $\{\cdot, \cdot\}_\nu = \{\cdot, \cdot\}'_\nu$. □
