Abstract

As a generalization of deterministic, nonlinear conservative dynamical systems, a notion of canonical conservative dynamics with respect to a positive, differentiable stationary density $\rho(x)$ is introduced: $\dot{x} = j(x)$ in which $\nabla \cdot \left( \rho(x) j(x) \right) = 0$. Such systems have a conserved “generalized free energy function” $F[u] = \int u(x,t) \ln \left( \frac{u(x,t)}{\rho(x)} \right) dx$ in phase space with a density flow $u(x,t)$ satisfying $\partial u_t = -\nabla \cdot (ju)$. Any general stochastic diffusion process without detailed balance, in terms of its Fokker-Planck equation, can be decomposed into a reversible diffusion process with detailed balance and a canonical conservative dynamics. This decomposition can be rigorously established in a function space with inner product defined as $\langle \phi, \psi \rangle = \int \rho^{-1}(x) \phi(x) \psi(x) dx$. Furthermore, a law for balancing $F[u]$ can be obtained: The non-positive $dF[u(x,t)]/dt = E_{in}(t) - e_p(t)$ where the “source” $E_{in}(t) \geq 0$ and the “sink” $e_p(t) \geq 0$ are known as house-keeping heat and entropy production, respectively. A reversible diffusion has $E_{in}(t) = 0$. For a linear (Ornstein-Uhlenbeck) diffusion process, our decomposition is equivalent to the previous approaches developed by R. Graham and P. Ao, as well as the theory of large deviations. In terms of two different formulations of time reversal for a same stochastic process, the meanings of dissipative and conservative stationary dynamics are discussed.

1 Introduction

With the recent development of stochastic thermodynamics in terms of mesoscopic entropy production [1, 2, 3, 4], free energy dissipation [5, 6, 7], work equalities and fluctuation theorems [8, 9, 10, 11], and the mathematical theory of nonequilibrium steady state [12, 13],
there is a revitalized interest in nonlinear stochastic dynamics, particularly those without detailed balance.

Nonlinear stochastic dynamics without detailed balance can be mathematically represented by irreversible Markov processes. For a general discrete state Markov process, either with discrete or continuous time parameter, a decomposition theorem is known. In a nutshell, the transition probability matrix of a Markov process, with respect to its stationary distribution, can be decomposed in terms of a symmetric and an anti-symmetric parts. The latter part can be further decomposed into many pure rotations among the discrete states. The notion of cycle kinetics arises in this analysis.

For continuous diffusion processes on $\mathbb{R}^n$ without detailed balance, such a decomposition has not been fully established, even though computations have revealed both stationary density and rotational flux as key determinants of a stationary process. A sophisticated analysis on a compact differentiable manifold with genus also exists. In the physics literature, R. Graham and coworkers have proposed and studied extensively a decomposition of non-gradient vector field in terms of Fokker-Planck equations, via WKB method and a Hamilton-Jacobi equation. But the program was ultimately abandoned due to technical difficulties. In recent years, P. Ao and coworkers have again proposed a related decomposition from a rather different starting point. However, the feasibility of this new approach has been rigorously demonstrated only for a linear system which is nearly equivalent, apart from the normalizability of the invariant density, to analyzing irreversible Ornstein-Uhlenbeck processes. Still, their emphasis on stable as well as unstable fixed points had suggested the possible applicability to nonlinear systems. A full analysis beyond heuristic for general nonlinear diffusion processes without detailed balance still is not available. See for more, and recent discussions.

The centrepiece of the Fokker-Planck equation of a diffusion process is a linear, partial differential operator $\mathcal{L}$. Assuming the existence of a unique stationary density $\rho(x) > 0, x \in \mathbb{R}^n$ and $\mathcal{L}(\rho) = 0$, an inner product in a function space can be introduced. For diffusion process with detailed balance, this functional analysis approach is reduced to the Sturm-Liouville problem. In the present work, we follow this approach and introduce an operator decomposition in terms of a symmet-
ric $\mathcal{L}_s$ and an anti-symmetric $\mathcal{L}_a$: $\mathcal{L} = \mathcal{L}_s + \mathcal{L}_a$. The partial differential equation (PDE) $(\partial/\partial t - \mathcal{L}_s)(u) = 0$ is a parabolic PDE with a self-adjoint elliptic operator $\mathcal{L}_s$, representing a reversible diffusion process and a gradient-like system, as expected for a symmetric operator. In sharp contrast, the PDE $(\partial/\partial t - \mathcal{L}_a)(u) = 0$ turns out to be a first-order hyperbolic PDE in which the $\mathcal{L}_a$ is only a first-order differential operator with respect to $x \in \mathbb{R}^n$.

We show that the anti-symmetric system corresponds to a generalization of the conservative nonlinear dynamics one usually studies [39], where the $\rho$ is uniform. One important example of this class of dynamics is Hamiltonian systems. We shall call the usual conservative dynamics $\dot{x} = g(x)$ with $\nabla \cdot g(x) = 0$ microcanonical-like. The terminology is borrowed from statistical physics where microcanonical system is a Hamiltonian dynamics in phase space with Liouville’s equation [40]. Then the dynamical system defined by $\mathcal{L}_a$ with $\dot{x} = j(x)$ in which $\nabla \cdot (\rho(x)j(x)) = 0$ could be called a canonical-like. Indeed, for the density function $u(x, t)$ in the phase space, a microcanonical-like dynamics has

$$\frac{d}{dt} \left[ - \int_{\mathbb{R}^n} u(x, t) \ln u(x, t) \, dx \right] = 0,$$

(2a)

a result known to Boltzmann [41]. Similarly in a canonical-like dynamics we have (see below)

$$\frac{d}{dt} \left[ \int_{\mathbb{R}^n} u(x, t) \ln \left( \frac{u(x, t)}{\rho(x)} \right) \, dx \right] = 0.$$

(2b)

In the present work, Eqs. (2a) and (2b) are used as the definitions for microcanonical and canonical conservative dynamics, respectively.

\section{Fokker-Planck differential operator decomposition}

A general Fokker-Planck equation is characterized by a symmetric, non-singular $n \times n$ diffusion matrix $A(x)$ and a vector field, $b(x)$, the drift. In the present work, we shall denote the linear differential operator in a function space

$$\mathcal{L}(\phi) = \nabla (A(x)\nabla \phi(x)) - \nabla (b(x)\phi(x)),$$

(3)

$$\mathcal{L}^*(\phi) = \nabla (A(x)\nabla \phi(x)) + b(x)\nabla \phi(x),$$

(4)

and adopt the inner product given in Eq. (1), in which $\rho(x)$ is the normalized stationary solution to the PDE $\mathcal{L}(\rho) = 0$. We assume the $\rho(x)$ is unique, positive and differentiable.
Then we have
\[
\langle \psi, L(\phi) \rangle = \int_{\mathbb{R}^n} \rho^{-1} \psi(x) \, dx \left\{ \nabla (A(x) \nabla \phi(x)) - \nabla (b(x) \phi(x)) \right\}
\]
\[
= \int_{\mathbb{R}^n} \left\{ \nabla [A(x) \nabla (\rho^{-1} \psi(x))] + b(x) \nabla (\rho^{-1} \psi(x)) \right\} \phi(x) \, dx
\]
\[
= \langle \rho L^* (\rho^{-1} \psi) , \phi \rangle.
\]

We now introduce symmetric and anti-symmetric operators
\[
L_s(\phi) = \frac{1}{2} \left\{ L(\phi) + \rho L^* (\rho^{-1} \phi) \right\}, \quad (5)
\]
\[
L_a(\phi) = \frac{1}{2} \left\{ L(\phi) - \rho L^* (\rho^{-1} \phi) \right\}. \quad (6)
\]

Then it is easy to verify:
\[
\langle \psi, L_s(\phi) \rangle = \frac{1}{2} \left( \langle \psi, L(\phi) \rangle + \langle L(\psi), \phi \rangle \right) = \langle L_s(\psi), \phi \rangle, \quad (7)
\]
\[
\langle \psi, L_a(\phi) \rangle = -\langle L_a(\psi), \phi \rangle, \quad (8)
\]
and \(L\) has a decomposition \(L = L_s + L_a\).

In physics literature, one usually prefers to write Fokker-Planck equation. However, in mathematical literature, a diffusion process is represented by its infinitesimal generator \(\tilde{L} = \nabla A(x) \nabla + b(x) \nabla\). Then one defines an inner product with respect to the invariant measure \(\rho(x)\) as \(\langle u, v \rangle^\rho = \int_{\mathbb{R}^n} u(x)v(x)\rho(x) \, dx\). With respect to \(\rho(x)\), the \(\tilde{L} = \rho^{-1}(x)\nabla (A(x)\rho(x) \nabla) + j(x) \nabla\) has its adjoint \(\tilde{L}^* = \rho^{-1}(x)\nabla (A(x)\rho(x) \nabla) - j(x) \nabla\), where the \(j(x)\) is defined in Eq. (21) below. The present paper chooses to work with the forward operator \(L\) rather than the backward operator \(\tilde{L}\).

3 Symmetric reversible diffusion

The multi-dimensional elliptic differential operator
\[
L_s(u) = \nabla \left( A(x) \nabla u(x) - (A(x) \nabla \ln \rho(x)) u(x) \right) \quad (9)
\]
is a Fokker-Planck type with diffusion tensor \(A(x)\) and drift \(A(x) \nabla \ln \rho(x)\). One can immediately check that \(\rho(x)\) is its stationary density. The diffusion process associated with \(L_s\) has been extensively studied in the past and is well understood.
The corresponding partial differential equation (PDE)

\[
\frac{\partial u(x,t)}{\partial t} = L_s(u(x,t))
\]  

is formally a gradient system

\[
\frac{\partial u}{\partial t} = \frac{\delta}{\delta u} \langle L_s(u), u \rangle. 
\]  

(11)

See [38] for many important properties associated with reversible diffusion processes.

**Potential function, entropy production and stochastic generalized free energy.** The “potential function” in Eq. (11) can be expressed as

\[
- \langle L_s(u), u \rangle = \int_{\mathbb{R}^n} \left[ \nabla \left( \frac{u(x,t)}{\rho(x)} \right) \right]^T A(x) \left[ \nabla \ln \left( \frac{u(x,t)}{\rho(x)} \right) \right] u(x,t) dx. 
\]  

(12)

Then for \(u(x,t)\) following the self-adjoint PDE (10) [45, 6, 7],

\[
\frac{dF(t)}{dt} = \langle \rho \frac{\partial u}{\partial t}, \ln \left( \rho^{-1} u \right) \rangle + \langle \rho u, u \rangle - \langle \mathcal{L}_s(u), \rho \ln \left( \rho^{-1} u \right) \rangle = -e_p. 
\]  

(14)

The \(e_p \geq 0\) is known as the entropy production rate for the reversible diffusion process [38, 12]. A stationary reversible diffusion, therefore, has \(e_p = 0\).

**Stochastic differential equation for trajectories.** One can also write a stochastic differential equation for the diffusion process described by Eq. (10). If we follow Itô’s notion of stochastic integration, we have

\[
dx_i(t) = \rho^{-1}(\bar{x}) \sum_j \left( \frac{\partial}{\partial x_j} A_{ij}(\bar{x}) \rho(\bar{x}) \right) dt + \sum_j \Gamma_{ij}(\bar{x}) dB_j(t),
\]

(15)

in which matrix \(A(\bar{x}) = \frac{1}{2} \Gamma(\bar{x}) \Gamma^T(\bar{x})\), and \(B_j(t)\) are standard Brownian motions. On the other hand, if one follows Stratonovich’s integration, one has

\[
dx_i(t) = \sum_j \left( A_{ij}(\bar{x}) \frac{\partial \ln \rho(\bar{x})}{\partial x_j} + \frac{1}{2} \sum_k \Gamma_{ik}(\bar{x}) \frac{\partial}{\partial x_j} \Gamma_{jk}(\bar{x}) \right) dt + \sum_j \Gamma_{ij}(\bar{x}) dB_j(t), 
\]

(16)
and if one takes the “divergence form” for the integration, as strongly advocated by P. Ao [32, 34], then

\[ dx_i(t) = \sum_j \left( A_{ij}(\vec{x}) \frac{\partial}{\partial x_j} \ln \rho(\vec{x}) \right) dt + \sum_j \Gamma_{ij}(\vec{x}) dB_j(t). \]  

(17)

4 Canonical conservative dynamics

On the other hand, the anti-symmetric partial differential operator is

\[ L_a (u) = \nabla \left( (A(x) \nabla \ln \rho(x) - b(x)) u(x) \right) \]

(18)

\[ = (A(x) \nabla \rho(x) - b(x) \rho(x)) \cdot \nabla (\rho^{-1}(x) u(x)). \]  

(19)

The corresponding PDE

\[ \frac{\partial u(x,t)}{\partial t} = L_a(u(x,t)) \]

(20)

is not diffusive but rather it is a first-order hyperbolic PDE. It is easy to verify that \( \rho(x) \) is again a stationary density for Eq. (20). Eq. (19) actually is the Liouville equation in the phase space for the nonlinear ordinary differential equation (ODE)

\[ \frac{dx}{dt} = b(x) - A(x) \nabla \ln \rho(x) \equiv j(x). \]  

(21)

The \( j(x) \) in Eq. (21) satisfies

\[ \nabla \cdot (\rho(x) j(x)) = 0. \]  

(22)

That is,

\[ \nabla \cdot j(x) + j(x) \cdot \nabla \ln \rho(x) = 0. \]  

(23)

Thereore, Eq. (21) is a canonical conservative system with respect to stationary density \( \rho(x) \). Since \( \rho(x) \) is an invariant density to the dynamics in Eq. (20), one can again consider the generalized free energy functional [44, 19, 6, 7]

\[ F[u(x,t)] = \int_{\mathbb{R}^n} u(x,t) \ln \left( \frac{u(x,t)}{\rho(x)} \right) dx. \]  

(24)

For the hyperbolic system, this is a generalization of Boltzmann’s \( H\)-function in which the stationary distribution \( \rho(x) = \text{constant} \) due to “equal probability a priori”. Then one has
\[
\frac{dF(t)}{dt} = \int_{\mathbb{R}^n} \frac{\partial u(x,t)}{\partial t} \ln \left( \frac{u(x,t)}{\rho(x)} \right) \, dx \\
= \int_{\mathbb{R}^n} j(x)u(x,t) \left[ \frac{\nabla u(x,t)}{u(x,t)} - \frac{\nabla \rho(x)}{\rho(x)} \right] \, dx \\
= -\int_{\mathbb{R}^n} \left( \nabla \cdot j(x) + j(x) \cdot \nabla \ln \rho(x) \right) u(x,t) \, dx \\
= 0. \tag{25}
\]

In the derivation we have used Eqs. (20) and (23) as well as assumed that \( u(x,t) \rightarrow 0 \) sufficiently fast when \( \|x\| \rightarrow \infty \).

The result in Eq. (25) is reminiscent of a Boltzmann’s result before he introduced his Stosszahlansatz. His \( H \)-function, \(-\int f(x,t) \ln f(x,t) \, dx\), actually is invariant with respect to time if \( f(x,t) \) follows strictly the phase space Liouville equation for a Hamiltonian dynamics [41]. One also notes that the \( L_2 \) norm of \( u(x,t) \) is conserved in a canonical conservative dynamics:

\[
\frac{d}{dt} \|u(x,t)\|_2 = \langle L_a(u), u \rangle = -\langle u, L_a(u) \rangle = 0.
\]

Actually, any functional \( \int_{\mathbb{R}^n} u G(u/\rho) \, dx \) is a conserved quantity for Eq. (20).

**Fixed points in canonical conservative system.** Eq. (23) indicates that \( \nabla \cdot j(x) = 0 \) at the fixed point of vector field \( j(x) = 0 \). Without loss of generality, let \( x^* = 0 \) be a fixed point: \( j(x^*) = 0 \). Then in the neighbourhood of \( x^* = 0 \) one has

\[
 j(x) = B x + \frac{1}{2} x^T G x + \cdots, \quad \rho(x) = \rho(0) + \bar{q} \cdot x + \cdots, \tag{26}
\]

in which the Jacobian matrix \( B \) has elements \( B_{\ell k} = \partial j_{\ell}(0)/\partial x_k \), tensor elements \( G_{\ell kh} = \partial^2 j_{\ell}(0)/\partial x_k \partial x_h \), and gradient \( \bar{q} \) has elements \( q_k = \partial \rho(0)/\partial x_k \). Then the Eq. (23) becomes

\[
 \rho(0) \text{Tr}[B] + \bar{q} B x + \text{Tr}[B] \bar{q} \cdot x + \frac{\rho(0)}{2} \sum_{\ell k} \{G_{\ell \ell k} x_k + G_{\ell k \ell} x_k\} + O(\|x\|^2) = 0, \tag{27}
\]

\( \forall x \). Since \( \rho(0) \neq 0 \) this yields \( \text{Tr}[B] = 0 \). Furthermore,

\[
 \sum_{\ell} \frac{\partial \ln \rho(0)}{\partial x_\ell} \frac{\partial j_\ell(0)}{\partial x_k} + \frac{\partial^2 j_\ell(0)}{\partial x_\ell \partial x_k} = 0. \tag{28}
\]

Hence, the fixed point of a canonical conservative system can not be a node or focus. It has to be either a saddle or a center, just as in a Hamiltonian system [39].

**Stationary points of \( \rho(x) \) in canonical conservative system.** Eq. (23) also indicates that \( \nabla \cdot j(x) = 0 \) at the stationary position of \( \rho \) where \( \nabla \rho(x^*) = 0 \). A similar local analysis
can be carried out near $x^s$, and one has
\[
\sum_{\ell} j_{\ell}(x^s) \frac{\partial^2 \rho(x^s)}{\partial x_{\ell} \partial x_k} + \frac{\partial^2 j_{\ell}(x^s)}{\partial x_{\ell} \partial x_k} = 0. 
\] (29)

**Planar canonical conservative system.** A planar canonical conservative system has
the general form $\dot{x} = \rho^{-1}(x, y) \partial H(x, y)/\partial y$, $\dot{y} = -\rho^{-1}(x, y) \partial H(x, y)/\partial x$. The phase portrait for this system is identical to the Hamiltonian system with $\rho = 1$. Indeed, $H(x, y)$ is a conserved quantity in the dynamics: $dH(x(t), y(t))/dt = 0$.

**Mapping to microcanonical conservative system via time change.** More generally, let $\rho(x) j(x) = f(x)$. Let $\hat{x}(t)$ be a solution to the microcanonical conservative system $\dot{x} = f(x)$. Then the solution to the canonical conservative system with same initial value is $x(t) = \hat{x}(\hat{t}(t))$ in which
\[
\hat{t}(t) = t_0 + \int_{t_0}^t \rho^{-1}(\hat{x}(s)) \, ds.
\]

5 General diffusion processes without detailed balance

We now bring the results from the above two sections to bear on the general diffusion processes.

**Decomposing free energy dissipation** $\frac{dF}{dt}$. In terms of $j(x)$, the “thermodynamic force” \cite{47} in a general diffusion generated by $\mathcal{L}$ \cite{38}
\[
b(x) - A(x) \nabla \ln u(x) = j(x) - \left\{ A(x) \nabla \ln \left( \frac{u(x)}{\rho(x)} \right) \right\},
\] (30)
in which the $j(x)$ characterizes the deviation of $b(x)$ from a gradient force; it does not involve $u(x)$. And since the $\rho(x)$ is uniquely determined by the diffusion matrix and drift, $j(x)$ is a stationary term strictly determined by the $A(x)$ and $b(x)$. The term in $\{ \cdots \}$ characterizes non-stationarity of the $u(x)$. Then we have,
\[
\left\langle \mathcal{L}(u), \rho \ln (\rho^{-1} u) \right\rangle = \left\langle \mathcal{L}_s(u), \rho \ln (\rho^{-1} u) \right\rangle + \left\langle \mathcal{L}_a(u), \rho \ln (\rho^{-1} u) \right\rangle.
\] (31)
The last term is zero for the canonical conservative system, e.g., Eq. (25). Therefore, the $\frac{dF}{dt}$ for a general diffusion process with $\mathcal{L}$ is entirely due to its symmetric part of the diffusion, $\mathcal{L}_s$. The canonical conservative dynamics generated by $\mathcal{L}_a$ has no contribution toward the generalized free energy dissipation of $\mathcal{L}$.
Non-negative source for generalized free energy $F[u]$. Another important quantity from physics, the house-keeping heat first proposed by Oono and Paniconi \cite{48, 6}, also called adiabatic entropy production \cite{7, 49, 9}, is

$$E_{in} = \int_{\mathbb{R}^n} \left( b - A\nabla \ln \rho \right) A^{-1}(x) \left( bu - A\nabla u \right) dx = \left\langle \rho j, A^{-1}(bu - A\nabla u) \right\rangle$$

(32)

for a general diffusion process. It is a type of projection of the thermodynamic driving force $\left( b(x) - A(x)\nabla \ln u(x) \right)$ onto the $j(x)$. It is zero for a reversible diffusion process with $j(x) = 0$. Noting the Eq. (30), we have

$$E_{in} = \left\langle \rho j, A^{-1}u_j \right\rangle - \left\langle \rho j, \rho \nabla (\rho^{-1}u) \right\rangle = \left\langle \rho j, uA^{-1}j \right\rangle \geq 0. \quad (33)$$

Then the free energy dissipation for a general diffusion

$$\frac{dF(t)}{dt} = E_{in}(t) - e_p(t), \text{ or } e_p(t) = E_{in}(t) - \frac{dF(t)}{dt}. \quad (34)$$

All three terms $e_p$, $E_{in}$, $-\frac{dF}{dt}$ are non-negative. A symmetric diffusion has $E_{in}(t) = 0 \ \forall t$ (Eq. 14); a canonical conservative dynamics has $\frac{dF(t)}{dt} = 0 \ \forall t$ (Eq. 25). A general diffusion process without detailed balance has $e_p(t)$ which is consist of non-negative $-\frac{dF}{dt}$ and $E_{in}$. Logically, we believe the mathematical Eq. (34) should be interpreted as a balance equation for the generalized free energy $F[u]$ with a source $E_{in}$ and a sink $e_p$. The fact that both $E_{in}$ and $e_p$ are non-negative indicates that they represent the authentic source and sink terms for the $F[u]$.

6 Ornstein-Uhlenbeck process: the linear case

We now consider the relationship between the above result and P. Ao’s decomposition \cite{32}. We shall explicitly work out the details for the Ornstein-Uhlenbeck (OU) Gaussian process \cite{35, 31}. We show that in the linear case, the two theories are equivalent. The present approach is also equivalent to that of R. Graham’s \cite{30} under the assumption of large deviation principle.

We consider linear vector field $b(x) = Bx$ and constant diffusion matrix $A$. The $n$-dimensional Fokker-Planck equation is

$$\frac{\partial u(x,t)}{\partial t} = \nabla \left( A \nabla u(x,t) - Bxu(x,t) \right). \quad (35)$$
It is easy to verify that the stationary solution has a Gaussian form \[ \rho(x) = \frac{1}{(2\pi)^{n/2} \det \Xi} \exp \left\{ -\frac{1}{2} x^T \Xi^{-1} x \right\}, \tag{36} \]
in which the covariant matrix \( \Xi \) satisfies the Lyapunov matrix equation \[ B\Xi + \Xi B^T + 2A = 0. \tag{37} \]
Accordingly, we have \[ Bx = A\nabla \ln \rho(x) + j(x) = -A\Xi^{-1} x + j(x), \quad j(x) = Jx, \tag{38} \]
where matrix \( J = B + A\Xi^{-1} \). We now show that matrix \( J \) can be written as \(-R\Xi^{-1}\) in which \( R \) is an anti-symmetric matrix. This is because of Eq. (37), \[ -R^T = (B\Xi + A)^T = \Xi B^T + A = -(B\Xi + A) = R. \]
Therefore, \( B = -(A + R)\Xi^{-1} \). So the linear stochastic differential equation \( dx(t) = Bxdt + \Gamma dB(t) \), with \( \frac{1}{2} \Gamma \Gamma^T = A \), can be re-written as \[ Mdx(t) = -\nabla \left( \frac{1}{2} x^T \Xi^{-1} x \right) dt + \Pi dB(t) \]
where \( \Pi = (A + R)^{-1} \Gamma \) and \( M = (A + R)^{-1} \). They are related via \[ M + M^T = \Pi\Pi^T, \tag{40} \]
because \[ \Pi^{-1} [(A + R)^{-1} + (A + R)^{-T}] \Pi^{-T} = \Gamma^{-1} [(A - R) + (A + R)] \Gamma^{-T} \]
\[ = 2\Gamma^{-1} A \Gamma^{-T} = I. \]
Eq. (39), together with (40), is Ao’s form of stochastic differential equation [32]. For the linear system, one also has an additional property: the gradient field \(-\Xi^{-1} x\) and canonical conservative dynamics \( Jx \) are actually orthogonal: \[ (\Xi^{-1} x)^T \cdot (Jx) = -x^T \Xi^{-1} R\Xi^{-1} x = - (\Xi^{-1} x)^T R (\Xi^{-1} x) = 0. \tag{41} \]
This orthogonality was noted in both [30] and [31]. See [35] and [31] for more discussions on irreversible OU processes.
7 Discussion

The above result provides some insights into the structural stability of non-gradient vector field \( b(x) \). Zeeman [50] has advocated an approach to structural stability based on \( \epsilon \)-noise perturbed dynamical systems. With respect to non-gradient field with a focus, he clearly noted one key difficulty in the Morse-Smale theory which requires a mapping from a focus to a node. While such a homeomorphism exists, “It is impossible, however, to make [such a map] smooth. ... Therefore in the attempt to capture density in two dimensions we have to abandon smoothness in the very definition of structural stability, and this, alas, is the beginning of the rot.” [50]

For simplicity, let \( A(x) = \epsilon \), then \( b(x) = j_\epsilon(x) + \epsilon \nabla \ln \rho_\epsilon(x) \) in which \( \rho_\epsilon(x) \) is the stationary density for the randomly perturbed dynamical system \( dx(t) = b(x)dt + \epsilon dB(t) \), and \( j_\epsilon(x) \) is a canonical conservative system. In the limit of \( \epsilon \to 0 \), whether a limit exists for \(-\epsilon \ln \rho_\epsilon(x)\) is precisely the theory of large deviations [51, 52]. If a differentiable limit \( U(x) \) exists, then one obtains a decomposition \( b(x) = j_0(x) - \nabla U(x) \). Moreover, since \( \nabla \cdot (\rho_\epsilon(x)j_\epsilon(x)) = 0 \forall \epsilon \), one also has \(-\epsilon j_\epsilon(x) \cdot \nabla \ln \rho_\epsilon(x) = \epsilon \nabla \cdot j_\epsilon(x) \). Thus \( j_0(x) \cdot \nabla U(x) = 0 \) if the convergence is uniform, i.e., the decomposition is orthogonal. This is indeed R. Graham’s theory [30, 52]. On the other hand, if \( \rho_\epsilon(x) \) has a nonzero limiting density \( \rho_0(x) \) on an attractor, then \( U(x) = 0 \) on the entire attractor. This has been explicitly shown for systems with limit cycles and invariant tori where the asymptotic stationary density \( \rho_\epsilon(x) \sim \rho_0(x)e^{-U(x)/\epsilon} \) [18]. However, if the limit \( U(x) \) is non-differentiable or worse, some weaker forms might still exist [53]. This is the technical challenges encountered by R. Graham and his coworkers [30]; further investigations are required. The present work could provide a different approach to the challenge.

Canonical conservative system with \( \frac{dF(t)}{dt} = E_{in}(t) - e_p(t) = 0 \) also leads to an interesting contradistinction between two views on time irreversibility. It is now known that entropy production \( e_p \) can be defined as the relative entropy between the probabilities of a trajectory \( \omega_t \) and its time reversal \( r(\omega_t) \), under the probability measure generated by \( L \) [15, 54, 55]. For a stationary diffusion, the probability for the \( r(\omega_t) \) with the measure generated by \( L = L_s + L_a \) is in fact the same as the \( \omega_t \) under the measure generated by \( L^- = L_s - L_a \) [55]. Now, if one introduces a different entropy production \( e^\#_p \) as [7, 49]

\[
e^\#_p = E^p \left[ \ln \left( \frac{dP}{dP^-}(\omega_t) \right) \right],
\]

(42)
in which the $P^{-\#}$ is defined as the probability of time-reversed trajectory $r(\omega_t)$ under the measure generated by $L^-$. Then $P^{-\#} = P$ and $e_p^\# = 0$ for any stationary diffusion, as well as the canonical conservative dynamics. With such a choice for the definition of time reversal, there will be no nonequilibrium steady state; only equilibrium in which $e_p^\# = E^\#_{in} = 0$. Indeed, a Hamiltonian system is considered to be time reversible in classical dynamics precisely due to the second type of time reversal [56]. Under $e_p$, cycle kinetics is interpreted as a driven phenomenon; under $e_p^\#$, cyclic dynamics is explained as a consequence of “inertia”. Indeed, a map between nonequilibrium steady state and Hamiltonian system with rotation has also been proposed in [57].

Finally, we note that the decomposition of a general diffusion process into an $L_a$ and an $L_s$ parts unifies nicely the earlier mathematical theories of dynamics formulated respectively by Newton and Fourier [58, 59]. We also note, with cosmological dynamics in mind, that in a long-time limit, the $L_s$ part of a dynamics vanishes, only the $L_a$ part remains with permanence.

I thank Ping Ao, Zhen-Qing Chen, Hao Ge, Da-Quan Jiang, Yao Li, Jin Wang, and Jianhua Xing for many helpful discussions. I particularly acknowledge Dr. P. Ao for his inspiration, encouragement, and comradeship. The present work grew out of a desire to reconcile the decomposition in his Darwinian dynamics [19] and the nonequilibrium steady-state circulation decomposition theorems in [20, 12].
