Department of Horticultural Sciences, Northeast Agricultural University, Harbin 150030, Heilongjiang, China

ABSTRACT. BRI1-EMS-suppressor 1 (BES1) is a transcription factor (TF) that functions as a master regulator of brassinosteroid (BR)-regulated gene expression. Here, we provide a complete overview of Solanum lycopersicum BES1 (SLB) genes, including phylogeny, gene structure, protein motifs, chromosome locations and expression characteristics. Through bioinformatic analysis, we compared the sequences of SLB genes, arabidopsis (Arabidopsis thaliana) genes, and chinese cabbage (Brassica pekinensis) genes. All of the gene sequences were divided into three groups by cluster analysis. SLB genes were mapped to the eight tomato (S. lycopersicum) chromosomes. Bioinformatic analysis showed that SLB genes shares similarities with the proteins from other plants, though different species exhibit specific features. The expression patterns of SLB genes in various tissues and under different abiotic conditions were analyzed by quantitative reverse transcription polymerase chain reaction. SLB genes were found to be induced by multiple stresses, particularly salt stress, indicating that SLB genes may have important roles in the response to unfavorable environmental changes. This study provides insight into the evolution of SLB genes and may aid in the further functional identification of BES1 proteins and the response of tomato plants to different stresses.

Transcription factors are proteins that bind to a specific nucleotide sequence and play a central role in gene regulation by activating or repressing the transcription of target genes. TFs can also activate a wide array of defense mechanisms in plants suffering from biotic and abiotic stresses (Century et al., 2008). BRI1-EMS-suppressor 1 is a new class of TFs that bind to and activate the promoters of BR genes (Yin et al., 2005). BRs regulate many plant growth and developmental processes, such as vascular development, cell elongation, stress responses, and senescence (Li and Chory, 1999). Extensive research has revealed the roles of BES1 TFs in plant growth, stress responses, and development (Guo et al., 2013; Ryu et al., 2010; Yin et al., 2005). Activated BES1 leads to the phosphorylation of TFs and other signaling components that regulate expression of downstream genes (Yin et al., 2005). Moreover, BES1 functions with BES1-interacting Myc-like 1 (BIM1), a basic helix-loop-helix TF, to synergistically bind to E box sequences to activate several BR-induced gene promoters (Yin et al., 2005). BRs have been shown to act as key components of the signaling pathways that mediate responses to abiotic and biotic stresses such as drought, hypoxia, and osmotic stress (Fujioka and Yokota, 2003). BES1 is phosphorylated and appears to be destabilized by the glycogen synthase kinase-3 BRASSINOSTEROID INSENSITIVE2 (BIN2), a negative regulator of the BR pathway (Yin et al., 2002). It has been revealed that the BES1 protein contains a putative nuclear localization sequence, followed by a highly conserved amino-terminal domain (N) shared among BES1 and family members, a BIN2 phosphorylation domain (P), a PEST motif, and a carboxyl-terminal domain (C) (Wu et al., 2016; Yin et al., 2005). More recent studies have shown that BES1 regulates the localization of BR receptor BRL3 within the provascular tissue of the arabidopsis primary root (Salazarhenao et al., 2016).

Tomato is an important crop grown in many areas around the world. In the present study, a genome-wide bioinformatic analysis was conducted to provide a relatively complete profile of the SLB gene family. The chromosomal localizations, gene structures, and conserved motifs in the promoter regions of these genes were analyzed, and used quantitative reverse transcription polymerase chain reaction (qRT-PCR) to analyze the expression of nine SLB genes in various tissues and under different abiotic stresses. In this study, we identified nine SLB genes by downloading their sequences and analyzing their gene structures, chromosomal locations, gene duplicates, and evolutionary mechanisms. We also discuss the kinetics of the corresponding transcription patterns in response to cold, drought, and salt (abiotic stress), as estimated by qRT-PCR. We report that some SLB genes are connected to tissue development and some gene expression was controlled by different abiotic stress reactions. These findings provide an important starting point for future research on the biological functions of the BES1 family in tomato.

Materials and Methods

PLANT GROWTH CONDITIONS AND STRESS TREATMENTS. For RNA isolation, the tomato cultivar Moneymaker [World Vegetable Center (AVRDC), Shanhua, Taiwan] was grown as the experimental plant material at the Northeast Agricultural University
Experimental Station (Harbin, China). Seedlings were grown in a mixture of perlite:vermiculite:plant ash (1:6:2) in a growth room under fluorescent lighting (200 μE·m⁻²·s⁻¹) at 22 to 24 °C, with 60% relative humidity and a 14/10-h light/dark cycle (Li et al., 2015). To investigate organ-specific expression profiles, samples of five types of organs (fibrous roots, young stems, young leaves, petals, and mature fruit) were collected from adult plants. Three samples of the tomato tissues were obtained from different plants. Two-month-old seedlings were used for all abiotic treatments. Seedlings at the four-leaf stage were put into growth chambers set at 4 °C under the fluorescent lighting (200 μE·m⁻²·s⁻¹) at 22 to 24 °C and a 14/10-h light/dark cycle with 60% relative humidity for cold treatment. Before the drought and salinity treatments, the seedlings were transferred to Hoagland's nutrient solution for 24 h (Hoagland and Arnon, 1937), under the fluorescent lighting (200 μE·m⁻²·s⁻¹) at 22 to 24 °C and a 14/10-h light/dark cycle 60% relative humidity and then irrigated with 200 mmol·L⁻¹ NaCl and 15% polyethylene glycol (PEG), respectively, for 24 h. Each treatment had three to five seedlings, and all the treatments had three biological replicates. Young leaf samples were collected at different time points (1.5, 3, 6, 12, and 24 h) and then immediately frozen in liquid nitrogen and stored at −80 °C before RNA extraction.

**Identification of SLB Genes.** Searches of the nucleotide and protein sequences of SLB genes were conducted in Sol Genomics Network (International Solanaceae Initiative, 2015). The BES1 protein sequences of arabidopsis and chinese cabbage were downloaded from The Arabidopsis Information Resource (Phoenix Bioinformatics Corporation, 2013) (Huala et al., 2001) and the BRAD database (Cheng et al., 2011). The BES1 domain (PF05687) obtained from the PFAM database was used as the query for a hidden Markov model search using the HMMER 3.0 program with a predefined threshold of E < 1e−5 (Artimo et al., 2012; Cui et al., 2016). The molecular weight and the theoretical isoelectric point (pI) of the obtained proteins were determined using the computing pl/Mw tool on the ExPASy server (Artimo et al., 2012).

**Phylogenetic tree analyses and sequence alignment.** Multiple sequence alignments of the amino acid sequences of the BES1 proteins of tomato, arabidopsis, and chinese cabbage were generated with ClustalX 2.0 software (Larkin et al., 2007). A phylogenetic tree based on the sequence alignments was constructed using MEGA 5.0 software (Tamura et al., 2011) and the neighbor-joining method with 1000 bootstrap replicates, maximum composite likelihood.

**Conserved domain and gene structure.** We used the sequence analysis software DNAMAN5.0 and the online software WebLogo (Crooks et al., 2004) to analyze conserved sequences of the tomato BES1 protein. The genomic sequences of SLB genes were then retrieved, and online Gene Structure Display Server (Center for Bioinformatics, 2015) was used to decipher the architecture of the SLB genes (Bai et al., 2016).

**Chromosomal distribution.** To determine the physical locations of SLB genes on chromosomes, Phytozome (Energy’s Joint Genome Institute, 1997) was used to identify the initial site of each gene. MapInspect software was then used to draw images of the locations of the SLB genes (Song et al., 2014). Standards regarding gene duplication followed the criteria described by Chen et al. (2012).

**RNA extraction and reverse transcription of cDNA.** RNA samples were extracted using the TRizol method according to the manufacturer’s instructions (Rio et al., 2010). Total RNA was treated with RNase-free DNase (TaKaRa, Dalian, China). Reverse transcription was performed with 1 μg of total RNA in a 20-μL volume with TransScript® RT/RI Enzyme Mix (Transgen Biotech, Beijing, China), according to the manufacturer’s instructions.

**Quantitative real-time PCR analysis.** The analysis was performed using the iQ5 real-time PCR platform (Bio-Rad Laboratories, Hercules, CA). Each 20-μL quantitative polymerase chain reaction mixture contained 2.5 μL of first-strand cDNA, 10 μL of 2 × FastStart Universal SYBR Green Master (Vazyme, Nanjing, China), and 0.2 μm of forward and reverse primers for each gene. The reaction was initiated with a preliminary step of 95 °C for 3 min, followed by 40 cycles of 95 °C for 10 s, and 60 °C for 30 s. The comparative Ct value method was adopted to analyze relative gene expression. RNA expression levels relative to the actin gene were calculated as 2^(-ΔΔCt) values according to a previous analysis (Pfaffl, 2001). The primers used for qRT-PCR were designed according to the genomic sequences of SLB genes using Primer 5 (Jie et al., 2013) software, and the Actin7 gene was used as an internal control (Wei et al., 2015) (Supplemental Table 1). The qRT-PCR data were clustered with the Pearson correlation distance metric using the average linkage method. The results are shown as color-coded heatmaps that reflect absolute signal values. The heatmaps were plotted using OmicShare tools (Gene Denovo, 2015), a free online platform for data analysis.

**Results**

**Identification and sequence alignment of SLB family genes in tomato.** Using the method described above, nine genes were identified as candidate BES1 genes in the tomato species. The primer sequences and the qRT-PCR results are provided in (Supplemental Table 1). The heatmaps were plotted using OmicShare tools (Gene Denovo, 2015), a free online platform for data analysis.

**Table 1.** Characteristic features of BR11-EMS-suppressor 1 (BES1) transcription factor gene family identified in tomato.

| Gene ID          | Gene name | Amino acids (no.) | Domain size (aa) | MW (Da)     | Theoretical pI | Aliphatic index | Gravy |
|------------------|-----------|-------------------|------------------|------------|----------------|----------------|-------|
| Solyc1g094580.2.1 | SLB1       | 695               | 69–213           | 77,864.45  | 5.37           | 71.41          | –0.466 |
| Solyc2g063010.2.1 | SLB2       | 319               | 9–153            | 34,474.87  | 9.38           | 65.52          | –0.516 |
| Solyc2g071990.2.1 | SLB3       | 324               | 2–142            | 34,908.89  | 8.14           | 57.78          | –0.606 |

ID = identity; SLB = Solanum lycopersicum BES1 gene 8; aa = amino acids; MW = molecular weight; pl = isoelectric point; Gravy = grand average of hydropathy.
genome. HMM analysis using the SMART/Pfam tool revealed that all of the deduced protein sequences contain DUF822, a conserved BES1 domain. The amino acid sequence lengths encoded by SLB genes ranges from 180 (SLB8) to 695 (SLB1). The molecular masses range from 20,389.00 (SLB8) to 77,864.45 (SLB1) Da and the pI values of the proteins from 5.37 (SLB1) to 9.38 (SLB2). The characteristic features of the SLB gene family are shown in Table 1.

Two conserved domains were identified in the SLB genes: DUF822 and glycosyl hydrolase 14 (Fig. 1). DUF822 is also known as BES1_N, comprising the N-terminal regions of several TFs. This sequence was classified as BES1/BZR1, a plant-specific TF that cooperates with other TFs such as BIM1 to regulate BR-induced genes. Located at the N-terminus, the domain is ≈110–148 amino acids. Only SLB1 and SLB7 exhibit the conserved glycosyl hydrolase 14 domain, corresponding to a family of glycoside hydrolases.

**Phylogenetic analysis of SLB genes.** A phylogenetic tree based on nine SLB, six arabidopsis AtBES1, and 15 chinese cabbage BrBES1 protein sequences was constructed. In this tree, the SLB gene sequences were divided into three main groups: Group I (5), Group II (10), and Group III (15) (Fig. 2). Group I contains the lowest number of BES1 sequences, including only SLB1 and SLB7, which exhibit both the DUF822 and glycosyl hydrolase 14 conserved domains. Group II is the largest tomato group, with four SLBs (SLB8 performed more similar to Group II genes than Group III after sequence alignment). Group III contains nine BrBES1, three SLB, and three AtBES1 sequences, thus constituting the family with the greatest number.

**Gene structure and conserved motif identification in tomato.** Considering that a gene structure is a typical imprint of evolution within a gene family, we analyzed the BES1 genes of the above three plants using the tools available on the GSDS website (Bo et al., 2015; Center for Bioinformatics, 2015). The genes in each group showed similar structures and introns (Fig. 3C). As almost all SLB genes contain one or two introns except SLB1 and SLB7, each SLB sequence is divided into many segments by introns. Among the nine SLB genes, two present a 9-exon/9-intron structure and seven present a 2-exon/1-intron structure. Interestingly, all BES1 genes in arabidopsis contain upstream/downstream area; all genes without upstream/downstream area belong to chinese cabbage and tomato.

The conserved motifs were analyzed using the MEME program (National Institutes of Health, 2015; Fig. 3B), and LOGOs of the protein motifs were obtained with MEME (Fig. 1). Ultimately, we identified 20 motifs (with an E-value cutoff <e–1.0) (Baloglu et al., 2014) (Supplemental Fig. 1). With the exception of AT1G32130, all of the sequences contain motif 1, motif 2, and motif 14 and belong to the main family of DUF822 conserved domains. Moreover, motifs 5, 11, 12, 13, 14, 18, and 19 were resharable by SLB1 and SLB7. Some of the other conserved motifs were also specifically found in Group I. The results indicated that genes from the same subfamily might share similar functions and motif compositions.

**Distribution of BES1 genes on tomato chromosomes.** We used MapInspect software to determine the chromosomal distribution of the SLB genes. All of the SLB sequences were mapped to the eight chromosomes of tomato. Chromosome 2 was the only chromosome containing two genes (SLB1 and SLB2), whereas no SLB genes are present on chromosomes 5, 6, 9, and 11. On average, one SLB gene occurs every 34.3 Mb. Gene duplication has been studied in many plant species (Wang et al., 2015). In tomato, two duplicated SLB genes were identified, which were divided into two groups: SLB3 and SLB4 belonging to Group II and SLB5 and SLB9 belonging to Group III. Both pairs are the result of segmental duplications, and no tandem duplicated genes were found.

**Expression patterns of SLB in various tissues.** To investigate the functional divergence of SLB genes, expression of all nine SLB genes was analyzed in different tissues under normal conditions by qRT-PCR (Fig. 4). With the exception of SLB2 and SLB5, all of the other genes showed high expression...
levels in roots. In the stem, only SLB2 was expressed at a high level, and both SLB4 and SLB5 presented high expression in leaves, with the latter only showing high expression in leaves. Petals were the organ which owns the greatest number of genes exhibited high expression, including SLB2, SLB6 and SLB7, SLB7 showed a significantly high expression level. SLB1 genes displayed high expression levels in all other tissues, though was highly expressed in fruit, indicating that SLB genes may not be involved in fructification.

Expression patterns of SLB under different abiotic conditions. To investigate the role of SLB genes, all nine SLB genes were selected for evaluation by qRT-PCR of comprehensive expression profiles under drought and cold treatments. The results showed (Fig. 5) that some SLB genes exhibit diverse gene expression patterns in response to different treatments (Fig. 5A). Under PEG treatment, some genes were downregulated, such as SLB2 and SLB5, whereas genes such as SLB1 and SLB6 were upregulated within 24 h; moreover, SLB2 showed a downward trend as the duration of stress progressed. In addition, expression of SLB1 was upregulated by >1.58-fold compared with that of the control treatment after 1.5 h of drought stress. These results suggest that both SLB1 and SLB2 are closely related to drought stress but may have different mechanisms. SLB1, SLB6, SLB7, and SLB8 were downregulated under cold treatment, and SLB9 expression displayed a tendency to decline initially and later increase. With the exception of SLB2, all of the other genes were significantly upregulated after 6 and 24 h of salt treatment. Moreover, expression of some genes was upregulated by >100-fold after 6 and 12 h of salt treatment compared with other treatment times. Thus, expression of these genes was clearly increased in response to salt treatment, indicating that they play an important role in resistance to salt stress in tomato. Interestingly, SLB2 was upregulated under both cold and 12 h of salt treatment. Hence, we deduce that SLB2 functions in both cold and salt stresses.

Discussion
Tomato is an important crop that is cultivated worldwide. According to PlantTFDB (Jin et al., 2017), BES1 genes have been discovered in 149 plant species in the past decade, with the number of genes in various species ranging from 2 to 42, and 30 BES1 genes have been analyzed. Advances in molecular analyses have improved our understanding of the BES1 TF family. Wu et al. (2016) identified 15 BES1 genes in Chinese cabbage and found that BES1 was present only in land plants. However, the BES1 genes of tomato have not been characterized to date, especially in response to abiotic stresses. In this study, we performed a comprehensive search for BES1 genes in the tomato genome and found nine. We used bioinformatics to analyze the BES1 TF family and the expression patterns of the encoding genes in different tissues and under different abiotic conditions.

According to our bioinformatics analysis, the tomato BES1 gene family can be divided into three groups, similar to the
categories of BES1 genes observed in Arabidopsis and Chinese cabbage (Wu et al., 2016). Although the SLB genes present a similar classification as Arabidopsis BES1 genes, their numbers in each group were different, proving that different plants show multiple duplications. The comparison of the homologs between species showed that SLB1 is homologous to Bra004944 (B. pekinensis), and SLB7 is homologous to Bra021962, which identified a closer relationship for tomato with Chinese cabbage than with Arabidopsis. For example, based on the patterns of gene expression, which were closely connected with gene function, we can predict the functions of tomato BES1 genes. Two conserved domains, BES1_N and glycosyl hydrolase 14, are present in tomato BES1 TFs (Fig. 1), a finding that is similar to previous results showing that Chinese cabbage BES1 contains BISON and glycosyl hydrolase 14 domains. All nine SLB genes harbor a BES1_N domain. Thus, the BES1_N type is the BES1 domain arrangement among BES1 family members in plants. Gene duplication occurs continuously during the evolution of living organisms and is considered a major cause of genome complexity and functional expansion (Magadum et al., 2013; Wei et al., 2016). Duplicated genes are highly similar in terms of their nucleotide sequence, gene structure, protein sequence, and chromosomal location. In our analysis of SLB, two pairs of putatively duplicated genes highly similar in their nucleotide sequence were discovered. For example, SLB3 on chromosome two and SLB4 on chromosome three encode proteins that are 95% identical in amino acid sequence (Fig. 6). Gene duplication can result in redundancy of gene function or generation of complementary genes. In this case, the duplicated BES1 genes may have similar or different expression patterns.

We identified expression of all nine tomato SLB genes in various tissues. Our results indicated high expression levels of SLB genes in roots but low expression levels in fruits. Espinosa-Ruiz et al. (2017) found that BR may control shoot boundaries and root meristem development in Arabidopsis, which indicates that BES1 genes may be closely associated with the growth of roots and less associated with fruit development. Moreover, all nine SLB genes were examined under different stress treatments via qRT-PCR. By regulating an array of TFs are crucial for controlling different mechanisms (Broun, 2004; Zhao et al., 2012). According to previous studies, Arabidopsis and Chinese cabbage BES1 genes are associated with stress responses (Wu et al., 2016). As abiotic stresses, such as drought, are causing increasing injury to crop production and quality, a thorough understanding of the molecular mechanisms involved in plant stress tolerance has become pivotal for the development of new strategies and technologies related to the increasing demand of agricultural production (Chen et al., 2015). The results of the present study revealed that almost all SLB genes were induced to some
degree by common abiotic stresses, including exposure to drought, low temperature, and salt (Fig. 5). In tomato, SLB2 may be associated with the drought response, as it exhibited a stable downregulation trend under drought conditions. Thus, we deduce that SLB2 cannot be resistant to drought stress. Moreover, genes such as SLB5, 6 may be associated with drought. It has been reported that *Gossypium hirsutum* BES1 mRNA (GenBank KP272000.1) showed high resistance to drought in drought environments after spraying BR (Wenkai et al., 2015). SLB9 likely contributes to cold stress endurance, as shown by its expression pattern, whereas other genes, such as SLB1, -6, -7, and -8 might be repressed by low-temperature treatments. However, no studies on the association of BES1 TFs with cold resistance are available in the literature. Nonetheless, as almost all of these genes were markedly upregulated after 6 and 24 h of salt treatment, BES1 TFs appear to play an important role in salt resistance in tomato. Previous work indicated that one BES1 gene, *BZR1* (*AT1G19350*) of *arabidopsis*, is over-expressed under cold, drought, and salt treatments (Li et al., 2009). SLB5 and SLB9 are in the same group (Group III), as is *AT1G19350*, so they may have similar function as *AT1G19350*. SLB2 was upregulated under cold and 12 h of salt treatment, and SLB9 showed specific expression under drought, salt, and cold treatments. Moreover, high levels of expression were detected under salt treatment compared with that under the other treatments (Fig. 5B). These findings suggest that BES1 TFs might be involved in stress-related regulatory networks, especially for salt stress.

In conclusion, this study is the first to comprehensively investigate BES1 TFs in tomato, and a preliminary evaluation of their expression profiles under various abiotic stresses was performed. We employed an improved method based on protein domain and phylogenetic analysis to classify BES1 proteins from tomato, *arabidopsis*, and *Chinese cabbage*, and this approach will be important for research in other species. Nine SLB genes were mapped to the eight chromosomes of 12 chromosomes of tomato, and two duplicated SLB genes were identified. In addition, tomato BES1 TFs were found to be related to stress responses. In the future, additional experiments should be conducted to determine the specific biological functions of each of these genes. However, the identification of putative functional motifs and the evaluation of expression profiles provide useful information for further exploration of the biological functions of each putative BES1 gene.

Supplemental Fig. 1. Sequence logos of BRI1-EMS-suppressor 1 domains in tomato. The overall height of the stack indicates the level of sequence conservation. The height of residues within the stack indicates the relative frequency of each residue at that position.

Supplemental Table 1. The primers were applied for quantitative real-time polymerase chain reaction amplification in this study.

| Gene name | Forward primer (5'-3') | Reverse primer (5'-3') |
|-----------|------------------------|------------------------|
| SLB1      | AGGCTCAGTCCCTCCTCAT    | TCGGAAACTAGTCAACCACAAA |
| SLB2      | TGGGAATCCCTCTCCAGGGT  | AGGCGGCATCGACTCAATCA   |
| SLB3      | CACGAGGCTACCGACATGGA  | TCTTCAACAATCCACAGGCTCCT |
| SLB4      | GTGAAAGCCTGGAAGGTTGA  | GCGAGCTAGCTAGCACTCA     |
| SLB5      | TGTTGGAGGTTTGGAGGTTT   | CCGTCACTCCCTCCATGATCGCT |
| SLB6      | TGGACAGTTGGAGCCATGGG  | AAGAGGAAAGGCGGCTTGG    |
| SLB7      | AGGCTCAGTCCCTCCTCAT    | TCGGAAACTAGTCAACCACAAA |
| SLB8      | GGGGATAGGGTTGTTGACAAA  | ACGTTGCGTGGAGGAAATC     |
| SLB9      | GTGAGGCTGAGGTTGTTACC   | GCAGCTCAGCTCCCTCCTC   |
| Actin-7   | ATTGTTGCTGAGGTTCCCG   | CGGAAACAGAAGGACACT     |

SLB = *Solanum lycopersicum* BRI1-EMS-suppressor 1.
