Dear Editor,

The patient was a 56-year-old woman with cirrhosis caused by hepatitis C virus. Blood test results showed preserved liver function, indicating Child-Pugh class A and modified albumin-bilirubin (mALBI) grade 1, but the α-fetoprotein (AFP) level was significantly increased to 10,530 ng/mL (normal range: 0–10 ng/mL). Dynamic computed tomography (CT) showed a hepatic mass, 40 mm in diameter, in the lateral segment of the liver, with strong and homogeneous enhancement in the arterial phase (shown in Fig. 1a). It presented hyperintensity in the hepatobiliary phase of gadolinium ethoxybenzyl diethylenetriaminepentaacetic acid-enhanced magnetic resonance imaging (EOB-MRI) (shown in Fig. 1b). Positron emission tomography showed marked fluorodeoxyglucose uptake by the tumor (shown in Fig. 1c). There was no intrahepatic or extrahepatic metastasis, but the lateral branch of the portal vein could not be detected, suggesting portal vein tumor thrombosis.

On diagnosis of unresectable hepatocellular carcinoma (HCC), considering high postoperative recurrence rate of HCC with portal vein invasion if resected without preceding treatment, atezolizumab and bevacizumab were initiated at 1,200 mg and 15 mg/kg, respectively. However, CT after the second course revealed an increase in tumor size (80 mm in diameter) (shown in Fig. 1d); AFP level also increased rapidly (shown in Fig. 2). Therefore, lenvatinib was initiated as the second-line therapy at a dose of 8 mg/day. Some adverse events induced by lenvatinib, such as hand-foot syndrome and thrombocytopenia, were observed. In particular, thrombocytopenia with a platelet count <50,000/μL required temporary interruption and dose reduction to 4 mg/day or 4 mg and 8 mg on alternate days when lenvatinib was restarted. With this therapy, AFP level decreased immediately, and CT 4 weeks after initiation revealed remarkable tumor shrinkage accompanied by decreased tumor vascularity and viability; the tumor size decreased by 50%, suggesting partial response on modified RECIST (shown in Fig. 1e).

Liver function was not impaired by atezolizumab plus bevacizumab and lenvatinib, indicating Child-Pugh class A and mALBI grade 1. Considering that the tumor was...
well controlled and that the liver function was good, we performed conversion hepatectomy 13 weeks after initiating lenvatinib. A yellowish-white tumor, 45 mm in diameter, was observed macroscopically (shown in Fig. 1f). Microscopically, the tumor was totally necrotic with no viable cells, and there was no vascular invasion (shown in Fig. 1g). No recurrence since 3 months postoperatively. To the best of our knowledge, this is the first case of pathological complete response of unresectable HCC to treatment with lenvatinib after failure of atezolizumab plus bevacizumab.

HCCs are classified into 3 classes based on the immune status of the microenvironment. Among the 3 classes, the “immune exclusion class,” accounting for around 30% of cases, is characterized by activation of β-catenin induced by CTNNB1 mutation and tends to be resistant to treatment with immune checkpoint inhibitors. Ueno et al. [1] showed that Wnt/β-catenin signaling induces the expression of organic anion-transporting polypeptide 1B3, suggesting HCC enhancement in the hepatobiliary phase in EOB-MRI is driven by CTNNB1 mutation. In our patient, considering that the lesion was also enhanced in the
phase with a relative enhancement ratio of 0.99, it might have been immune exclusion HCC driven by CTNNB1 mutation; this may explain the poor effect of atezolizumab plus bevacizumab.

Although homogeneously enhanced HCC in dynamic CT arterial phase treated with lenvatinib has a lower early objective response rate than heterogeneously enhanced HCC [2], our case represented a remarkable response to lenvatinib. One of the reasons may be that the response to lenvatinib in iso-high intensity HCC in the hepatobiliary phase of EOB-MRI was not diminished like that in atezolizumab plus bevacizumab, which was reported by Kubo et al. [3]. Second, it has been reported that lenvatinib was initiated immediately after the failure of anti-PD-1/PD-L1 therapy, which is expected to have a more potent anti-tumor effect due to synergism than when initiated alone as first-line therapy [4]. This is supported by the fact that anti-PD-1 antibody binds to PD-1 for >20 weeks.

Moreover, Yamauchi et al. [5] showed that FGFR4 expression is higher in HCC with activated Wnt/β-catenin signaling and that HCC with FGFR4 expression has a significantly better response rate among patients with advanced HCC treated with lenvatinib. Our case could be driven by a CTNNB1 mutation leading to high FGFR4 expression. Hence, regardless of previous therapy, treatment with lenvatinib would be appropriate.

Various treatment options are currently available for unresectable HCC. It is important to be aware of the presence of cases primarily resistant to atezolizumab plus bevacizumab and consider alternative therapy in such cases.

**Conflict of Interest Statement**

The authors have no conflicts of interest to declare.

**Funding Sources**

Not applicable.

**Author Contributions**

T.K. and H.A. contributed to pretreatment diagnosis and systemic treatment. S.K., T.K., and H.O. performed the operation. K.S., N.O., and K.A. carried out the pathological diagnosis. Y.J. wrote the manuscript. All authors have read and approved the final version of the manuscript, and all authors fulfill the COPE (Committee on Publication Ethics) requirements for authorship.
