Abstract

Objective: The role of hormone receptors as a prognostic and therapeutic tool in breast cancer is widely accepted. The aim of this study was to analyze the receptor status in breast cancer with histopathological characteristics of the tumor.

Methods: In the present study, immunohistochemical assay of 62 tumor block of patients of breast carcinoma was performed to know the hormone receptor status as well as histological examination.

Results: 62 samples were taken to study hormonal status and their relation with histopathological factors. Out of 62 breast cancer specimen available for immunohistochemical testing for ER/PR. The result of the study showed 45.16% cases were ER+/PR+, 4.84% cases ER+/PR-, 6.45% ER-/PR+ and 43.55% cases were ER-/PR-. A significant association was seen between histologic grade and hormone receptor status.

Conclusion: The Estrogen receptor and Progestron Receptor negative cases were found to be high grade disease on histological evaluation. The ER/PR status of all breast tumour should be evaluated for IHC. ER/PR positive breast tumour has better prognosis and respond better to treatment.

Keywords: Breast carcinoma; Estrogen; Progesterone; Histopathology

Abbreviations: ER: Estrogen Receptor; PR: Progesterone Receptor; Her2: Human Epidermal Growth Factor Receptor-2; H&E: Hematoxylin and Eosin; HPF: High- Power Fields

Introduction

Breast cancer is the most common cancer in women worldwide, with nearly 1.7 million new cases diagnosed in 2012 (second most common cancer overall). This represents about 12% of all new cancer cases and 25% of all cancers in women [1]. Breast cancer is a leading cause of death in women [2]. Incidence of breast cancer is low in India compared to western countries, but it is associated with poor prognosis and high mortality, may be due to late presentation at advanced stages [3]. It shows heterogeneity in its clinical behavior. Prognosis and management of breast cancer are influenced by the classic variables such as histological type and grade, tumor size, lymph node status, status of hormonal receptors- estrogen receptor (ER) and Progesterone receptor (PR) of tumor [4]. Determining the estrogen receptor (ER), progesterone receptor (PR) and human epidermal growth factor receptor-2 (Her2/neu) receptor status in breast cancer has become practice as survival advantage for patients with hormones receptor positive status by treatment with adjuvant hormonal or chemotherapeutic regimens. It is well known that strong ER-positive cases benefit from endocrine therapy alone, in contrast to those with low to moderate ER positivity [5].

PR status is independently associated with disease-free and overall survival. Patients with ER, PR positive tumors have a better prognosis than patients with negative expression of ER and PR tumors [6]. Immunohistochemistry is primarily a research tool in our population. Hormone receptors study is not routinely measured as it is expensive. This could impact treatment decisions and patients are sometimes treated empirically with tamoxifen which is not always required. The present study was planned keeping in mind predictive importance of receptor status for the prognosis of illness and application of appropriate therapy. The objective was to determine receptor status and it’s correlation with histopathological Grade of the tumor in an Indian population.
Objectives
To correlate the Histopathological grade with ER and PR receptor status of breast carcinoma

Materials and Methods
This was an observational study carried out in R L Jalappa Hospital, Tamaka, Kolar. Samples of sixty two patients with histological proven diagnosis of breast carcinoma from January 2011 to December 2015 were selected for this study. Modified radical mastectomy specimens were subjected for routine histopathological examination and immunohistochemical analysis. Clinical details were archived from the files. Specimens were routinely fixed 24-48 hours in 10% neutral buffer formalin and were grossly examined and representative tissue bits were taken according to standard guidelines and then processed. Sections were stained with routine hematoxylin and eosin (H&E) stain. Histopathological features were determined, amples Swere histologically graded according to Modified Bloom-Richardson-Elston grading system. ER / PR status was evaluated by immunohistochemistry technique with monoclonal antibodies (DAKO) using antigen-antibody Streptavidin immunoperoxidase technique and other tumor related parameters were reported as per standards. ER and PR positivity was assessed using Allred Score system. The Allred score combines the percentage of positive cells and the intensity of the reaction product in the most of the carcinoma. The 2 scores are added together for a final score with 8 possible values. A simplified Allred score groups 0 and 2; 3 and 4; 5 and 6; and 7 and 8 for 4 possible values [7] (Tables 1 & 2).

Table 1: Proportion score (PS).

| Score | % of Positive cells |
|-------|---------------------|
| 0     | 0                   |
| 1     | <1                  |
| 2     | 1-10                |
| 3     | 11-33               |
| 4     | 34-66               |
| 5     | 67-100              |

Table 2: The proportion score and intensity score are added together for a total score.

| Total score: PS+ IS | Interpretation |
|---------------------|----------------|
| 0,2                 | Negative       |
| 3, 4, 5, 6, 7, 8    | Positive       |

Elston- Ellis modification of Scarff- Bloom-Richardson grading system was used for histological grade. It evaluates the amount of tubule formation, the extend of nuclear pleomorphism and the mitotic count. Each variable is given a score of 1, 2, or 3 and the score are added to produce a grade. 2 The mitotic score was determined by the number of mitotic figures found in 10 consecutive high- power fields (HPF) in the most mitotically active part of the tumor. Only clearly identifiable mitotic figures were counted. Diagnosis age was categorized as<30, 30-39, 40-49, 50-59 and ≥60 yrs.

Results
Sixty two cases of breast carcinomas cases were tested for ER and PR status in relation to histological grading of tumor. In the present study female patients with breast carcinoma were aged between 3rd and 8th decade of life. The youngest was 25 years and oldest 79 years the mean age was 52.66 years. Majority (63%) were in age group of 40 to 59 yrs (Table 3).

Table 3: Age distribution of the patients.

| AGE GROUP (In Yrs ) | NUMBER OF CASES |
|---------------------|-----------------|
| <30                 | 1               |
| 30-39               | 8               |
| 40-49               | 14              |
| 50-59               | 19              |
| ≥60                 | 20              |

The morphological categories were infiltrating ductal carcinoma, not otherwise specified (52 cases- 83.9%) followed by medullary carcinoma (6 cases, 9.7%); infiltrating lobular carcinoma (2 cases- 3.2%); mucinous carcinoma and infiltrating papillary carcinoma 1 (0.7%) case each (Table 4).

Table 4: Number of patients in different morphological categories.

| Morphological Categories | No of Cases |
|--------------------------|-------------|
| Infiltrating Ductal Carcinoma(NOS) | 52          |
| Medullary Carcinoma       | 6           |
| Mucinous Carcinoma        | 1           |
| Infiltrating Lobular Carcinoma | 2   |
| Infiltrating Papillary Carcinoma | 1 |

The most frequent tumor grade was grade I (49%) followed by grade III (40%) and grade II (11%) (Table 3). The result of the study showed 45.16% cases were ER+/PR+, 4.84% cases ER+/PR-, 6.45% ER-/PR+ and 43.55% cases were ER-/PR. Expression of ER and PR found to be significantly associated with tumor grade (p=0.02) (Tables 5-8).

Table 5: Frequency of tumor grade.

| Histological grade | No of cases | Percentage |
|--------------------|-------------|------------|
| Grade I            | 30          | 49%        |
| Grade II           | 7           | 11%        |
| Grade III          | 25          | 40%        |
Discussion

Improved breast cancer treatment requires integration of clinical pathology and cancer biology which could affect patient outcome. ER, PR and her2/neu are well-established procedures in routine breast cancer management mainly as prognostic factors for adjuvant hormone therapy [8,9]. In our study, expression of ER, PR was found to be 48.39 %, 41.9 % respectively which correlate well with other studies [10,11]. Hormonal receptor status has shown that overall positivity rate for ER and PR was lower in India than that reported in Western literature. In European and American population, 60-80 % patients were found with positive receptor expression [10]. This may be due to lower average age at diagnosis or racial difference.

The tumor grade I were more common in our study followed by grade III and II contrast to other studies [12]. This is a similar to some other studies where well-differentiated breast cancer is more common than the poorly differentiated cancer [10,13]. In our study, ER and PR correlated well with grade I (p=0.001 and p=0.02 respectively). Tumor size is one of the important predictors of tumor behavior in breast cancer. Our results described the significant association of tumor size with an expression of ER and PR (p=0.02 & p=0.04) respectively. Our results confirmed that non-reactivity of hormonal receptors increases with increase in tumor size.

Infiltrating ductal carcinoma was the most common histological type similar to other studies followed by medullary carcinoma in our study where as in other studies Infiltrating lobular carcinoma being the second most common type [14,15].

Our study provides convincing evidence for a non-significant association between expression of ER, PR and lymph node metastasis. Similar results have been documented in other studies [16,17].

Conclusion

Immunohistochemical analysis of ER and PR receptors is widely available at a reasonable cost and is prognostic as well as somewhat predictive. This study confirms that receptor expression of ER and PR found to be significantly associated with tumor grade and tumor size. However, No association with node metastasis and ER, PR expressions was observed. Further functional analyzes of ER and PR receptors are needed to investigate the effects of compounds in inhibiting cancer in humans. These findings could have clinical importance in breast cancer treatment.
