Abstract

Background: Lung cancer is the leading cause of cancer deaths worldwide, with a five-year overall survival rate of only 15%. Cancersous inhibitor of PP2A (CIP2A) is a human oncogene inhibiting PP2A in many human malignancies. However, whether CIP2A can be a new drug target for lung cancer is largely unclear.

Methodology/Principal Findings: Normal and malignant lung tissues were derived from 60 lung cancer patients from southern China. RT-PCR, Western blotting and immunohistochemistry were used to evaluate the expression of CIP2A. We found that among the 60 patients, CIP2A was undetectable or very low in paratumor normal tissues, but was dramatically elevated in tumor samples in 38 (63.3%) patients. CIP2A overexpression was associated with cigarette smoking. Silencing CIP2A by siRNA inhibited the proliferation and clonogenic activity of lung cancer cells. Intriguingly, we found a natural compound, rabdocoetsin B which is extracted from a Traditional Chinese Medicinal herb Rabdosia coetsa, could induce down-regulation of CIP2A and inactivation of Akt pathway, and inhibit proliferation and induce apoptosis in a variety of lung cancer cells.

Conclusions/Significance: Our findings strongly indicate that CIP2A could be an effective target for lung cancer drug development, and the therapeutic potentials of CIP2A-targeting agents warrant further investigation.

Introduction

Nearly 1.5 million people were diagnosed with lung cancer and 1.4 million people were estimated to die from it in 2007 [1]. The two major forms of lung cancer are non–small cell lung cancer (NSCLC) and small cell lung cancer (SCLC). About 85% of lung cancers are NSCLC, which can be divided into three major histological subtypes: squamous cell carcinoma, adenocarcinoma, and large-cell carcinoma. SCLC represents about 15% of lung cancers [2]. Smoking causes all types of lung cancer but is most strongly linked with SCLC and squamous-cell carcinoma; adenocarcinoma is the most common type in patients who have never smoked [2]. Current treatment is determined by the histologic type of lung cancer and stage at diagnosis, including surgery, platinum doublet therapy, radiation therapy and targeted therapy. Unfortunately, the prognosis of lung cancer is poor with a only 15% of five-year overall survival rate for all stages combined [1]. Therefore, there is an urgent need to identify more effective molecular targets and new targeted therapies for lung cancer.

Cancerous Inhibitor of PP2A (CIP2A) is a human oncogene that stabilizes c-Myc by inhibiting protein phosphatase 2A (PP2A)-mediated dephosphorylation of MYC at serine 62 [3]. In addition to inhibiting the degradation of c-Myc, CIP2A appears to be regulated in a positive feedback loop with c-Myc by promoting each other's expression [4]. CIP2A is over-expressed in human neck and head carcinomas, colon, breast, and gastric cancer, and is inversely correlated with disease outcome in gastric cancer [3–7]. However, whether CIP2A could be a new drug target for cancers is not fully investigated, and the anti-tumor activity of CIP2A-targeting agents remains largely unknown. We studied the expression of CIP2A in lung cancer and screened for lead compounds that could target CIP2A [8]. Here we show that CIP2A is markedly upregulated in lung cancer tumors compared to patient-matched adjacent normal lung tissues, and report that a natural compound which triggers downregulation of CIP2A exhibits significant antitumor activity in NSCLC cell lines.

Results

CIP2A is over-expressed in lung cancer and is associated with cigarette smoking

We tested the expression of CIP2A at protein level in nonmalignant and malignant cells, and found that CIP2A was...
highly expressed in lung cancer cell lines (A549, H1975, 95D and L78) compared to normal human embryonic lung fibroblasts (HLF and MRC5) and normal human bronchial epithelial cells (HBEpiC) (Figure 1A). We then analyzed CIP2A in 60 lung cancer samples from patients came from southern China whose baseline characteristics were listed in Table 1. We showed that CIP2A was over-expressed in 38 (63.3%) tumor specimens assayed by western blotting (Figure 1B). However, in the 60 patient-matched adjacent normal lung tissues, CIP2A was undetectable in 57 (95%) samples, and was weakly expressed in 3 (5%) specimens where its expression was much lower than that in tumor samples of the same patients. In samples from 2 patients with inflammatory pseudotumor, CIP2A was not detected in both the pseudotumor and adjacent lung tissues (Figure 1C). Immunohistochemistry

CIP2A overexpression is associated with cigarette smoking

We analyzed the correlation between CIP2A overexpression and some clinicopathologic variables. The data demonstrated that CIP2A overexpression in lung cancer was significantly correlated with histologic type of squamous cell carcinoma (p = 0.003) and male gender (p = 0.008) (Table 1) that were shown to strongly link with cigarette smoking [2,9]. Moreover, our data clearly showed that the high expression of CIP2A was associated with smoker patients (p = 0.004). No significant difference in the CIP2A status was observed according to the pathological stage (p = 0.639) and age (0.082) (Table 1). In an attempt to clarify the most significant factors related to CIP2A overexpression, the multivariate analyses were performed, and the multivariate logistic regression analysis (Table 2) demonstrated that cigarette smoking was the only significant variable associated with CIP2A overexpression in lung cancer (p = 0.008).

| Characteristics | Cases, n | CIP2A-high, n (%) | P value |
|-----------------|----------|-------------------|---------|
| Gender          |          |                   |         |

Rabdocoetsin B is a CIP2A-targeting natural compound

Our central goal was to identify new drug targets and provide lead compounds for drug development. We screened for CIP2A-targeting small molecules by analyzing their effects on CIP2A expression, and identified a natural compound extracted from a Chinese medicinal herbal Rabdosia coetsa, rabdocoetsin B [13,14] (Figure 4A), could downregulate CIP2A at protein level at 5 to 20 μM in A549 cells (Figure 4B). In H1975 cells, Rabdocoetsin B also triggered downregulation of CIP2A at 5 to 10 μM (Figure 4C). We analyzed the mechanism of CIP2A down-regulation caused by Rabdocoetsin B, and found that rabdocoetsin B significantly inhibited the transcription of CIP2A in a dose-dependent manner (Figure 4D) assessed by real-time RT-PCR.

Rabdocoetsin B inhibits CIP2A-modulated phosphorylated Akt

In hepatocellular carcinoma cells, CIP2A up-regulates phospho-Akt (pAkt) and decreases Akt-related PP2A activity, whereas silencing CIP2A re-activates PP2A [15]. Since Akt is constitutively active in lung cancer cells and promotes cellular survival and resistance to chemotherapy and radiation [16,17], we examined

the effect of CIP2A on pAkt in lung cancer. We showed that CIP2A silencing by specific siRNA resulted in down-regulation of pAkt but not pERK, PCNA, β-catenin, EGFR or Src (Figure 5A). We then investigated whether rabdocoetsin B could modulate the expression of pAkt, and found that treatment with rabdocoetsin B at 5 to 10 μM also down-regulated pAkt in A549 (Figure 5B) and H1975 (Figure 5C) cells. We further showed that in H1975 cells upon rabdocoetsin B at 10 μM, CIP2A was markedly downregulated in 6 to 12 h and became undetectable in 48 h (Figure 5D), while pAKT was decreased in 18 h (Figure 5D). These results were confirmed in A549 cells treated with rabdocoetsin B (Figure 5E), indicating that this compound can inhibit the CIP2A-Akt pathway in lung cancer.

Effects of Rabdocoetsin B on lung cancer cells

We evaluated the effects of rabdocoetsin B on lung cancer cells expressing wide-type (WT) or mutant EGFR. We showed that rabdocoetsin B exhibited significant cytotoxic effects on A549, NCI-H1975, HCC827, SPC-A-1, GLC-82, L78 and 95D lung cancer cell lines (Figure 6, A and B). Rabdocoetsin B induced apoptosis of A549 cells (Figure 6C) with activation of casp-8 and casp-9 and cleavage of PARP (Figure 6D). Rabdocoetsin B also caused activation of casp-8 and casp-9 and cleavage of PARP in NCI-H1975 cells (Figure 6E). These results indicate that rabdocoetsin B inhibits proliferation and induces apoptosis of lung cancer cells via activating the endogenous and exogenous apoptosis pathways.

Discussion

CIP2A is an auto-antigen [7] that is over-expressed in human neoplasms [3–7,18–21]. Peng [22] showed that in American-based patients, CIP2A is increased in 61 of the 72 (84.7%) lung cancer tissue specimens, which is significantly higher than in normal lung tissues (14.3%, 9/63). Recently, Dong et al [23] reported that in 29 patients from Northern China, CIP2A is over-expressed at mRNA level in 24 cases (82.7%) in tumor samples compared with their corresponding normal tissues; CIP2A protein (detected by immunohistochemistry) is found to be over-expressed in 72.2% of 90 lung cancer samples and correlated with poor survival. We test CIP2A expression in 60 patients from Southern China [8], and report that CIP2A is drastically increased in 63.3% (detected by western blotting) or 67.2% (at mRNA level) of tumor specimens compared to adjacent normal tissues (Figure 1).

We show for the first time that CIP2A overexpression is associated with cigarette smoking. In the 60 lung cancer patients examined in this study, 28 of 36 (77.8%) smoker patients show increased expression of CIP2A in the tumor samples compared to their adjacent normal specimens, whereas 10 of 24 (41.7%) nonsmoker cases exhibit up-regulated CIP2A at protein level (p = 0.004) (Table 1). Currently smoking continues to be more prevalent among men (63%) than women (3.8%) [24]. We report here that CIP2A is over-expressed in 30/40 (75%) and 8/20 (40%) in men and women patients (p = 0.008) (Table 1), respectively. We also find that CIP2A is elevated in 17/19 (89.5%) patients with squamous cell carcinoma, whereas 17/35 (48.6%) patients with adenocarcinoma have over-expressed CIP2A (p = 0.003) (Table 1). The multivariate logistic regression analysis clearly demonstrates that smoking is the only significant variable associated with CIP2A overexpression in lung cancer in our setting (p = 0.008) (Table 2). While the overall smoking rate in the North and Northeast sectors is higher than that in the South and East of China, the prevalence of environmental tobacco smoke exposure among nonsmokers in Northern China is significantly higher than that in nonsmokers in Southern China [24,25]. These may contribute to the difference in CIP2A expression between patients in our setting and Dong’s report [23]. Tobacco smoke which causes approximately 5–6 million deaths per year and 31% and 6% of all lung cancer deaths in middle-aged men and women respectively [26], can induce genetic and epigenetic changes and reduce DNA repair capacity [2]. Zhao et al [27] recently showed that in human gastric cell lines, Helicobacter pylori infection can induce CIP2A expression via bacterial oncoprotein Cag-A caused activation of the Src and MEK/ERK signal pathways. Though NNK (0.1 to 50 μM) fails to upregulate CIP2A in HBEpitC and BEAS-2B cells in up to 18 days in our study (Figure 2), we can not exclude the possibility that NNK may perturb the expression of the oncoprotein in a longer exposure time course, and this hypothesis warrants further investigation.

CIP2A is critical for lung cancer cell growth, since CIP2A knockdown by specific siRNA results in significant inhibition of cell proliferation and transformation in vitro and in vivo (Figure 3 and Figure S1). These data indicate that CIP2A could be an attractive target for novel anti-lung cancer drugs. Interestingly, we identify a natural compound rabdocoetsin B, can down-regulate CIP2A protein in lung cancer cells (Figure 4, A through C) by inhibiting its expression at mRNA level (Figure 4D). Studies show that CIP2A can up-regulate pAkt [15], and our results confirm that CIP2A silencing can decrease pAkt (Figure 5A). We further show that rabdocoetsin B also inhibits pAkt (Figure 5, B through E). Rabdocoetsin B inhibits the growth and induces apoptosis of a variety of lung cancer cells (Figure 6, A through E). Our data thus provide a lead compound for CIP2A-targeting anti-tumor therapeutics.

Materials and Methods

Patient samples

Use of the samples was approved by the Institutional Review Board of Institute of Zoology, Chinese Academy of Sciences and
Figure 3. CIP2A is required for lung cancer cells’ growth and transformation. doi:10.1371/journal.pone.0020159.g003
The Cancer Hospital, Sun Yat-Sen University. All tumor and adjacent normal tissue samples were obtained with written informed consent from patients at the Cancer Hospital, Sun Yat-Sen University. For RT-PCR analysis, tissue specimens were ground in liquid nitrogen-cooled mortar, RNA was extracted using the Trizol (Invitrogen), and RT-PCR experiments were performed using PrimeScript® One Step RT-PCR Kit Ver.2 (TaKaRa) according to the manufacturer’s protocol. The sequences of primers used for CIP2A are as follows: forward 5'-CCATATGCT-CACTCAGATGATGT-3' and reverse 5'-GTGTATCATCTCCA-CAGAGGTT-3' [5].

For Western blot assay, tissue specimens were ground in liquid nitrogen-cooled mortar, tissue powder was suspended in lysis buffer (50 mM Tris-HCl [pH 7.4], 150 mM NaCl, 1% triton X-100, 1% sodium deoxycholate, 0.1% SDS, 1 mM Na3VO4, 1 mM NaF, 1 mM EDTA, 1 mM PMSF, complete protease inhibitor cocktail) and cleared by centrifugation. Equal amounts of samples were separated by SDS-PAGE, transferred to nitrocellulose and immunoblotted with anti-CIP2A or anti-β-actin antibody.

Immunohistochemical assay and scoring of immunoreactivity were performed as described [28]. Formalin-fixed, paraffin-embedded lung cancer tissue specimens (5 μm) were deparaffinized and subjected to a heat-induced epitope retrieval step for 2 min. The H2O2 (3%) was used to block endogenous peroxidase activity for 10 min. The sections were then washed with PBS. The rabbit polyclonal anti-CIP2A antibody was applied to the slides at a dilution of 1:500 at 4°C overnight. Detection was achieved with the Immunohistochemistry kit (pv-6001) (Zhongshan Golden Bridge Biotechnology Co., Ltd, Beijing, China) according to the manufacturer’s protocol. Sections were colored with 3, 3'-diaminobenzidine (DAB) and counterstained with hematoxylin, dehydrated, treated with xylene, and mounted. CIP2A protein levels were scored as described [29].

Agents
Rabdocoetsin B was extracted from Rabdosia coetsa by Professor Han-Dong Sun. The 3-(4, 5)-dimethylthiazol (–zyl)-3, 5-di-
Phenyltetrazoliumromide (MTT) was purchased from Amresco, Inc. (Solon, OH). PE Annexin V-7AAD Apoptosis Detection kit was obtained from BD Biosciences (San Jose, CA, USA).

Antibodies

The antibodies used in this study were as follows: anti-β-Actin (Sigma), anti-casp-9 (C9), anti-casp-8 (1C12), anti-PARP, anti-phospho-p44/42 MAPK, anti-EGFR, anti-Src and anti-β-catenin (Cell signaling), anti-CIP2A (2G10-3B5), anti-pAKT and ATK (Santa Cruz Biotechnology); anti-ERK2 (Abcam); anti-PCNA (Abmart); anti-rabbit or anti-mouse HRP-conjugated secondary antibody (Pierce); Rabbit Polyclonal anti-CIP2A (Novus Biologicals, Inc). Detection was performed by using a Chemiluminescent Western detection kit (Cell Signaling).

Figure 5. Downregulation of CIP2A leads to decrease of phosphorylated Akt in lung cancer cells. (A): A549 cells were transfected with NC or CIP2A-specific siRNA for 72 h, and the expression of indicated proteins were detected using Western blots. (B and C): A549 (B) and H1975 cells (C) were treated with rabdocoetsin B (RdB) at indicated concentrations for 48 and 24 h, respectively, and Western blots were performed to analyze the expression of proteins indicated. (D and E): H1975 (D) and A549 (E) cells were treated with rabdocoetsin B (RdB) for indicated time points, and Western blot analysis was carried out with antibodies specific for the indicated proteins. β-actin is used as a loading control.

doi:10.1371/journal.pone.0020159.g005
Cell culture

The lung cancer lines NCI-H1975 and A549 and human embryonic kidney HEK-293 cells were obtained from the American Tissue Culture Collection (ATCC) and human embryonic lung fibroblast MRC-5 cells were purchased from the Cell Resource Center, Chinese Academy of Medical Sciences (Beijing). Normal human bronchial epithelial cells (HBEPiC, Catalog Number: 3210) were purchased from ScienCell (ScienCell Research Laboratories, San Diego, California). Human lung squamous carcinoma cell lines L78 and highly metastatic large-cell lung cancer cell lines 95D were obtained from the Cell bank of Chinese Academy of Sciences (Shanghai), and human embryonic lung fibroblast HLF cells were purchased from Kenqiang Instrument Co., Ltd (Shanghai, China). BEAS-2B bronchial epithelial cells were provided by Professor Hongbin Ji at Shanghai Institute for Biological Sciences, Chinese Academy of Sciences. A549, HLF and BEAS-2B cells were cultured in Dulbecco modified Eagle medium (DMEM) containing 10% fetal bovine serum (FBS; Gibco/BRL, Grand Island, NY), 100 U/ml penicillin, 100 μg/ml streptomycin. HBEPiC cells were cultured in a serum-free Bronchial Epithelial Cell Medium (BECM, Cat. No. 3211, ScienCell Research Laboratories) containing essential and non-essential amino acids, vitamins, hormones, growth factors and trace minerals. L78, 95D and NCI-H1975 cells were cultured in RPMI 1640 supplemented with 10% fetal bovine serum (FBS; Gibco/BRL, Grand Island, NY), 100 U/ml penicillin, 100 μg/ml streptomycin. MRC-5 cells were cultured in MEM/EBSS medium supplemented with non-essential amino acids, 10% fetal bovine serum (FBS; Gibco/BRL, Grand Island, NY), 100 U/ml penicillin and 100 μg/ml streptomycin.

Assessment of cell proliferation and apoptosis

Cells were treated with Rabdocoetsin B for indicated concentration and time points. Cell proliferation was determined using MTT assay. Cell viability was estimated by trypan blue dye exclusion. Externalization of phosphatidylserine was assayed by flow cytometry. Western blots were performed to detect the expression of apoptosis regulators in A549 (D) and H1975 cells (E).

doi:10.1371/journal.pone.0020159.g006
PE Annexin V-7 AAD Apoptosis Detection kit (BD Biosciences, San Jose, CA) according to manufacturer’s instruction.

**Quantitative real-time PCR**

Quantitative real-time PCR was performed in CFX™384 Real Time System (Bio-Rad) using SYBR® Premix Ex Taq™ (Perfect Real Time) (TaKaRa Code: DRR041) according to the manufacturer’s instruction. Primers for CIP2A and Actin were as follows: CIP2A: forward sequence, 5′-TGCGGCACTTGAGGTAGAATTTCC-3′; reverse sequence, 5′-ACTGCTCAAAGGCAACTGAAAT-GC-3′; Actin: forward sequence, 5′-ATGCCTCA-CGGAAATGTGCCTTTA-3′; reverse sequence, 5′-AGCCATGC-CAATCTGACCTTTGTT-3′. Levels of CIP2A mRNA were expressed as the ratio versus actin based on the CT values.

**siRNA assays**

Using HiPerFect Transfection Reagent (Qiagen, Crawley, UK) according to the manufacturer’s protocol, cells were transfected with 100 nM double-stranded siRNA oligonucleotides [3]. The siRNA sequences were 5′-CUUGUGUGUGUUGUUGACGGUGT-3′ (CIP2A siRNA1), 5′-ACCAUUGAUUUCCUAAGAATTT-3′ (CIP2A siRNA2) [3], and 5′-UUCCUCGGACGUGUCAC-GUTT-3′ (negative control (NC) siRNA).

**Clonogenic assay**

For foci formation, A549 or L78 cells transfected with negative control or CIP2A-specific siRNA were seeded in triplicate onto 35 mm plates (300 cells per plate). After 14 days of culturing, cells were stained with Giemsa and clones containing more than 50 cells were counted. For soft-agar colony formation assay, cells were suspended in 1 ml DMEM (for A549 cells) or RPMI 1640 (for L78 cells) containing 0.3% low-melting-point agarose (Amresco, Solon, OH) and 10% FBS and plated on a bottom layer containing 0.6% agarose in 35 mm plate (1,000 cells/plate) in triplicate. After 2-3 weeks culturing, plates were stained with Giemsa and colonies were counted using a light microscope.

**Murine models**

All animal studies were conducted according to protocols approved by the Animal Ethics Committee of the Institute of Zoology, Chinese Academy of Sciences, with the approval ID of AEC2010070202. All mice used in this study were bred and maintained in a specific pathogen-free environment. Nude mice (n = 8) were injected subcutaneously with A549 cells (4 × 10⁶) transfected with NC or CIP2A-specific siRNA into right and left flanks respectively, and tumor was calculated as described [12].

**Statistical analysis**

Differences between data groups were evaluated for significance using Student t-test of unpaired data, χ² test or one-way analysis of variance and Bonferroni post-test. The tumor volume was analyzed with one-way ANOVA and independent sample t test using the software SPSS 12.0 for Windows (Chicago, IL). The association between CIP2A high expression and clinicopathological feature was assessed using either χ² test or the Fisher exact test, and a backward stepwise multivariate logistic regression analysis was carried out to investigate the most significant variables related to CIP2A over-expression after adjustment. P values <.05 were considered statistically significant. All experiments were repeated at least three times and the data were presented as the mean±SD unless noted otherwise.

**Supporting Information**

Figure S1 The effects of CIP2A depletion on the L78 cells’ growth and transformation. (A): Western blot analysis of CIP2A protein expression in L78 cells 72 h after transfection with NC or CIP2A-specific siRNA. (B and C): Flat plate clone formation assay for clonogenic activity of L78 cells 72 h after transfection with NC or CIP2A-specific siRNA. (B): Representative light microscopy images. (C): Quantitation of foci counting. Shown is mean±SD of three independent experiments. (D and E): Soft-agar colony formation assay of L78 cells transfected with NC or CIP2A-specific siRNA. (D): Representative light microscopy images. (E): Quantitation of foci counting. (TIF)

**Acknowledgments**

We thank Professors Zhu Chen, Sai-Juan Chen and Zhen-Yi Wang at Shanghai Institute of Hematology for their long-term support. The authors thank Professor Jukka Westermarck at University of Turku, Finland for providing the pcDNA3.1-CIP2A construct, and Professor Hongbin Ji at Shanghai Institute for Biological Sciences, Chinese Academy of Sciences for providing the BEAS-2B cells.

**Author Contributions**

Conceived and designed the experiments: G-BZ. Performed the experiments: LM ZL ZH Y-QL J-XP W-LX. Analyzed the data: LM G-BZ. Contributed reagents/materials/analysis tools: H-DS. Wrote the paper: LM G-BZ. Clinical study: Z-SW J-M X-QC.
