Multi-Rate Control Design Leveraging Control Barrier Functions and Model Predictive Control Policies

Ugo Rosolia and Aaron D. Ames

Abstract—In this paper we present a multi-rate control architecture for safety critical systems. We consider a high level planner and a low level controller which operate at different frequencies. This multi-rate behavior is described by a piecewise nonlinear model which evolves on a continuous and a discrete level. First, we present sufficient conditions which guarantee recursive constraint satisfaction for the closed-loop system. Afterwards, we propose a control design methodology which leverages Control Barrier Functions (CBFs) for low level control and Model Predictive Control (MPC) policies for high level planning. The control barrier function is designed using the full nonlinear dynamical model and the MPC is based on a simplified planning model. When the nonlinear system is control affine and the high level planning model is linear, the control actions are computed by solving convex optimization problems at each level of the hierarchy. Finally, we show the effectiveness of the proposed strategy on a simulation example, where the low level control action is updated at a higher frequency than the high level command.

I. INTRODUCTION

Autonomous systems are designed to take control actions upon sensing the environment around them. The decision making process is usually divided into different layers. For instance, in autonomous driving the top layer determines a goal or intention, such as lane keeping, merging or overtaking. Then, a high level planner computes a desired collision-free trajectory, which is then fed to a low level controller that computes the control action. Each layer operates at different frequency and it is designed using model of increasing accuracy and complexity. This hierarchical architecture is used in several applications, for instance in bipedal locomotion [1], [2], autonomous driving [3], [4] and power grids [5], [6].

Combining high level planners with low level controllers has been extensively studied in literature [7]–[17]. Safety can be guaranteed using low level filters which, given a desired high level command, compute the closest safe control action using control barrier functions [7]–[9] or feasibility of an MPC problem [10]. The high level planner may be designed using a simplified model and the planned trajectory can be tracked using low level controllers. The tracking error and the associated tracking policy can be computed using Hamilton-Jacobi (HJ) reachability analysis [11] or sum-of-squares programming [12], [13]. Finally, high level planning and low level control can be implemented using nonlinear tube MPC strategies [14]–[17], where the difference between the planned trajectory and the actual one is over approximated using Lyapunov based analysis or Lipschitz properties of the nonlinear dynamics.

In the aforementioned papers, the low level and high level control actions are updated at the same frequency. In this paper, we consider a high level planner which operates at a lower frequency than the low level controller. Furthermore, in our formulation we allow the high level planner to reset its internal state as a function of the current state of the system. Our contribution is threefold. First, we introduce sufficient conditions that guarantee recursive constraint satisfaction for a multi-frequency high level planning and low level control architecture. Second, we present a control design which leverages CBFs for low level control and MPC for high level planning. We show that when the true system is nonlinear control affine and the planning model is linear, then the proposed strategy is implemented solving convex optimization problems. Third, we benchmark the proposed strategy against linear and nonlinear MPC policies. Simulation results demonstrate the benefit of the proposed multi-rate architecture, where the low level control action is updated at a higher frequency than the high level command.

This paper is organized as follows. In Section II we introduce the problem formulation. Section III describes the control architecture and the sufficient conditions which guarantee safety. The synthesis process is described in Section IV and it is demonstrated on a numerical example in Section V.

Notation: The Minkowski sum of two sets \( \mathcal{X} \subset \mathbb{R}^n \) and \( \mathcal{Y} \subset \mathbb{R}^n \) is denoted as \( \mathcal{X} \oplus \mathcal{Y} \), and the Pontryagin difference as \( \mathcal{X} \ominus \mathcal{Y} \). The set \( \mathcal{K}^\beta \) is the set of extended class-\( \mathcal{K}^\beta \) functions \( \beta \) which are strictly increasing and \( \beta(0) = 0 \). Finally, given a function \( f : \mathbb{R}^n \to \mathbb{R}^m \) and a set \( \mathcal{X} \subset \mathbb{R}^n \) we denote the set \( f(\mathcal{X}) = \{ y \in \mathbb{R}^m : \exists x \in \mathcal{X} \text{ such that } y = f(x) \} \).

II. PROBLEM FORMULATION

This section introduces the system model and the synthesis objectives. Consider a piecewise nonlinear model:

$$\Sigma : \begin{cases} \dot{x}(t) = f(x(t), u(t), v(t)), & t \in \mathcal{T} = \bigcup_{k=0}^{\infty}(t_k, t_{k+1}) \\ x^+(t) = \Delta(x^-(t)), & t \in \mathcal{T}^c = \bigcup_{k=0}^{\infty}(t_k) \end{cases},$$

where the state $x \in \mathbb{R}^n$, the set $\mathcal{T}$ collects the open intervals from time $t_k$ to time $t_{k+1}$ and its complement $\mathcal{T}^c$ collects the time instances $t_k$. As a result, the above system (1) evolves accordingly to the differential equation $\dot{x}(t) = f(x(t), u(t), v(t))$ between time $t_k$ and time $t_{k+1}$. On the other hand, at time $t_k$ the system evolution is defined by the reset map $\Delta(\cdot)$, where $x^-(t) = \lim_{\tau \downarrow t} x(\tau)$ and $x^+(t) = \lim_{\tau \uparrow t} x(\tau)$ are the right and left limits of a trajectory $x(t)$ which is assumed left continuous. Furthermore, we assume that the input $u \in \mathbb{R}^d$ is a continuous function of the state $x$ and the input $v \in \mathbb{R}^d$ is a piecewise-constant function which is updated when $t \in \mathcal{T}^c$, i.e.,

$$\Pi : \begin{cases} u(t) = \pi_u(x(t), v(t)), & \dot{v}(t) = 0, & t \in \mathcal{T} \\ u^+(t) = u^-(t), \ v^+(t) = \pi_v(x^-(t)), & t \in \mathcal{T}^c \end{cases}. \quad (2)$$

The above control policies (2) in closed-loop with system (1) results in a piecewise nonlinear autonomous system, which evolves on a discrete and a continuous level (see Fig. 2).

**Objective:** Our goal is to steer the system from a starting state $x_0$ to a goal state $x_g$ while satisfying the following state and input constraints:

$$\begin{align*}
x(t) &\in \mathcal{X}, \quad \forall t \in \mathcal{T}, \\
x^+(t) &\in \mathcal{X}_d \subseteq \mathcal{X}, \quad \forall t \in \mathcal{T}^c, \\
u(t) &\in \mathcal{U}, \ v(t) \in \mathcal{V}, \forall t \geq 0.
\end{align*} \quad (3)$$

III. FRAMEWORK ARCHITECTURE AND PROPERTIES

In this section we present the multi-rate control architecture. First, we introduce an augmented model, which is composed by the piecewise nonlinear system (1) and a high level planning model. The latter is affected by the piecewise constant input $v$ and it used to compute the planner state $\bar{x}$. Afterwards, the planned trajectory together with the input $v$ are fed to the low level controller which computes the control action $u$, as shown in Figure 1.

**A. Augmented System**

The augmented system is defined as

$$\Sigma_x : \begin{cases} \dot{x}(t) = f(x(t), u(t), v(t)), & t \in \mathcal{T} = \bigcup_{k=0}^{\infty}(t_k, t_{k+1}) \\ \dot{x}(t) = f_x(\bar{x}(t), v(t)), & t \in \mathcal{T}^c = \bigcup_{k=0}^{\infty}(t_k) \\ x^+(t) = \Delta(x^-(t)), & t \in \mathcal{T}^c = \bigcup_{k=0}^{\infty}(t_k) \end{cases},$$

and the control actions are given by the policies

$$\Pi_x : \begin{cases} u(t) = \pi_u(x(t), \bar{x}(t), v(t)), & \dot{v}(t) = 0, & t \in \mathcal{T} \\ u^+(t) = u^-(t), \ v^+(t) = \pi_v(x^-(t)), & t \in \mathcal{T}^c \end{cases}, \quad (4)$$

where $\mathcal{T}$ and $\mathcal{T}^c$ are defined as in (3) and $\bar{x} \in \mathbb{R}^n$ represents the planned state which is affected by the piecewise input $v$.

**B. High Level and Low Level Properties**

In this section, we define four properties associated with the high level planner and low level controller. As we will discuss later on, when these properties hold the closed-loop system is guaranteed to recursively satisfy state and input constraints (3).

Consider the closed-loop system (1)-(5) and let $t_k$ be the time at which the $k$th discontinuous transition occurs, i.e.,

$$x^+(t_k) = \Delta(x^-(t_k), u^-(t_k), v^-(t_k)) \forall k \in \{1, 2, \ldots\}.$$  

We defined the error $e = x - \bar{x}$ and we introduce the following error dynamics:

$$\Sigma_e : \begin{cases} \dot{e}(t) = f_e(x(t), u(t), v(t), \bar{x}(t)), & t \in \mathcal{T} \\ e^+(t) = \Delta_e(x^-(t)), & t \in \mathcal{T}^c \end{cases},$$

where $\mathcal{T}$ and $\mathcal{T}^c$ are defined as in (3), and the reset map $\Delta_e(\cdot)$ is designed so that the following properties hold.

**Property 1 (low level safety).** The control policy $\pi_v(\cdot)$ from (5) guarantees low level safety for the closed-loop system (4)-(5), if there exists a set $S_e \subseteq \mathcal{X}_d$ such that $\forall x^+(t_k) \in S_e \cap \mathcal{X}_d$ and $\forall v^+(t_k) \in \mathcal{V}$ we have that

$$x(t) \subseteq S_e \text{ and } u(t) \in \mathcal{U}, \forall t \in (t_k, t_{k+1}]. \quad (7)$$

Basically, the above property guarantees that state and input constraints are satisfied when the system evolves smoothly between time $t_k$ and time $t_{k+1}$. In particular, if at time $t_k$ the state $x^+(t_k)$ belongs to the set $S_e \cap \mathcal{X}_d$, then the low level controller $\pi_v(\cdot)$ guarantees state and input constraint satisfaction until the next discontinuous transition at time $t_{k+1}$.

**Property 2 (low level tracking).** The control policy $\pi_v(\cdot)$ from (5) guarantees low level tracking for the closed-loop system (4)-(5), if there exists a set $S_e$ such that $\forall v^+(t_k) = x^+(t_k) - \bar{x}^+(t_k) \in S_e$, $\forall x^+(t_k) \in S_e \cap \mathcal{X}_d$ and $\forall v^+(t_k) \in \mathcal{V}$ we have that

$$e(t) = x(t) - \bar{x}(t) \subseteq S_e, \forall t \in (t_k, t_{k+1}]. \quad (8)$$

![Fig. 2. Representation of the piecewise nonlinear closed-loop system 1 and 2. In the above figure we dropped the dependence on time to simplify the notation. When $t \in \mathcal{T}^c$, the reset map $\Delta(\cdot)$ and the control policy $\pi_v(\cdot)$ determine the system’s state $x^+$ and the input $v^+$, respectively. When $t \notin \mathcal{T}$, the system evolves accordingly to the differential equation $\dot{x} = f(x, u, v)$ and the control actions $u = \pi(x)$ and $v = 0.](image)
The low level tracking property ensures that the difference between the planned trajectory and the true state is contained into the set \( \mathcal{S}_e \) for all time \( t \in (t_k, t_{k+1}] \). The above Properties [12] guarantee that the planned trajectory can be safely executed by the true system.

**Property 3 (high level safety).** The control policy \( \pi^v(\cdot) \) from [5] guarantees high level safety for the closed-loop system (4)-(5), if for the initial conditions \( x(0) = \bar{x}(0) + e(0) \in \mathcal{S}_x \cap \mathcal{X}_d \) and \( e(0) \in \mathcal{S}_e \) we have that
\[
\vartriangle(z) = \mathcal{S}_c, \quad \forall z \in \mathcal{S}_c, \quad \forall k \in \{0, 1, \ldots\}.
\]

**Property 4 (high level tracking).** The reset map \( \mathcal{D}_e(\cdot) \) from [6] guarantee high level tracking for the closed-loop system (4)-(5), if for the initial conditions \( x(0) = \bar{x}(0) + e(0) \in \mathcal{S}_x \cap \mathcal{X}_d \) and \( e(0) \in \mathcal{S}_e \) we have that
\[
\mathcal{D}_e(z) = \mathcal{S}_c, \quad \forall z \in \mathcal{S}_c, \quad \forall k \in \{0, 1, \ldots\}.
\]

C. Safety Guarantees

In this section, we show that when the control policies from [5] satisfy Properties [12], the closed-loop system (4)-(5) does not violate state and input constraints [3]. This fact will be used in Section IV to design a multi-rate control architecture that leverages CBFs for low control and MPC policies for high level planning.

**Theorem 1.** Consider the closed-loop system (4)-(5). Assume that Properties [12] are satisfied and let \( x(0) = \bar{x}(0) + e(0) \in \mathcal{S}_x \cap \mathcal{X}_d \) and \( e(0) \in \mathcal{S}_e \). Then, the closed-loop systems (4)-(5) satisfies state and input constraints [3] for all time \( t \geq 0 \).

**Proof:** The proof proceeds by induction. Assume that after the \( k \)th discontinuous transition \( x^+(t_k) \in \mathcal{S}_x \cap \mathcal{X}_d \) and \( e^+(t_k) = x^+(t_k) - \bar{x}(t_k) \in \mathcal{S}_e \), then by Property [12]
\[
x(t) \in \mathcal{X}_c, \quad u(t) \in \mathcal{U}, \quad \forall t \in (t_k, t_{k+1}].
\]

Furthermore, by Property [2] we have that at time \( t_{k+1} \)
\[
x^-(t_{k+1}) \subseteq \bar{x}^-(t_{k+1}) + \mathcal{S}_e.
\]

The above equation together with Property [3] implies that
\[
x^+(t_{k+1}) \subseteq \mathcal{S}_x \cap \mathcal{X}_d, \quad v(t_k) \in \mathcal{V}, \quad \forall k \in \{0, 1, \ldots\}.
\]

Finally, from Property [4] we have
\[
e^+(t_{k+1}) = x^+(t_{k+1}) - \bar{x}^+(t_{k+1}) \in \mathcal{S}_e.
\]

**IV. SYNTHESIS: LEVERAGING CBFs AND MPC**

In this section, we discuss how the properties from Section III-B may be used to synthesize a safe controller. First, we show that Control Barrier Functions (CBFs) may be used to enforce low level safety and low level tracking. Afterwards, we design a Model Predictive Controller (MPC) to enforce high level safety and high level tracking.

We consider a control affine system where the input is given by the summation of the continuous control action \( u \) and the piecewise constant action \( \bar{v}(t_k) \).

\[
\Sigma^a : \begin{cases}
\hat{x}(t) = f(x(t)) + g(x(t))(u(t) + v(t)), & t \in \mathcal{T} \\
x^+(t) = \Delta(x^{-}(t)), & t \in \mathcal{T}^c
\end{cases}
\]

where \( \mathcal{T} = \cup_{k=0}^{\infty} (kT, (k+1)T) \), \( \mathcal{T}^c = \cup_{k=0}^{\infty} \{kT\} \) and \( 1/T \) is the frequency at which the high level command is updated. Furthermore, we assume the \( f \) and \( g \) are locally Lipschitz continuous with respect to their arguments and that the map \( \Delta(\cdot) \) is affine, as stated in Assumption [1]. Finally, the augmented model is given by

\[
\Sigma^a_{\mathcal{Z}} : \begin{cases}
\dot{z} = \begin{bmatrix} \dot{x} \\ \dot{\bar{x}} \end{bmatrix} = f^a(z) + g^a(z)(u + v), & t \in \mathcal{T} \\
\begin{bmatrix} x^+ \\ \bar{x}^+ \end{bmatrix} = \begin{bmatrix} \Delta(x) \\ \Delta(\bar{x}) \end{bmatrix}, & t \in \mathcal{T}^c
\end{cases}
\]

where we dropped the dependence on time \( t \) to simplify the notation and the continuous evolution of the planning state \( \bar{x} \) is described by linear dynamics, i.e., \( \dot{\bar{x}} = A\bar{x} + Bv \).

**Assumption 1.** The functions \( f \) and \( g \) are locally Lipschitz continuous and the reset map \( \Delta(\cdot) \) from (14) is affine. Consequently, the reset map \( \Delta \) can be written as \( \Delta(x) = Tx + g \), for some matrix \( T \in \mathbb{R}^{n \times n} \) and some vector \( g \in \mathbb{R}^n \).

A. Control Barrier Functions

In this section, we show that CBFs [8] can be used to enforce low level safety and low level tracking. Furthermore, we introduce a Control Lyapunov Function (CLF) which is used to reduce the tracking error. Finally, we combine the CBFs and CLF into a QP, which defines the low level control policy from Figure I.

First we define the following sets:

\[
\mathcal{S}_x = \{ x \in \mathbb{R}^n : h_x(x) \geq 0 \} \subseteq \mathcal{X}_c,
\]

\[
\mathcal{S}_e = \{ e \in \mathbb{R}^n : h_e(e) \geq 0 \},
\]

which will be used to check if Properties [12] hold. Furthermore, we define \( ||x||_{Q_x} = x^T Q x \) and we introduce the candidate Lyapunov function

\[
V(z) = ||x - \bar{x}||_{Q_e},
\]
which penalizes the deviation of the true system from the planned trajectory.

Finally, the CBFs associated with the sets in \([16]\), and the CLF \([17]\) are used to define the following CLF-CBF Quadratic Program (QP):

\[
\min_{u \in U, y} \||u||^2 + c_1 \gamma^2
\]

s.t. \[
\frac{\partial V(z)}{\partial z} (f^a(z) + g^a(z)(v + u)) \leq -c_2 V + \gamma
\]

\[
= -c_2 V + \gamma
\]

Remark 1. We underline that Assumption \([2]\) is satisfied for some \(\alpha_1 \in \mathbb{K}^c\) and \(\alpha_2 \in \mathbb{K}^c\) when the set \(I\) is robust control invariant for system \([4]\) and mild assumptions on the Lie derivative of \([4]\) hold (see \([8]\) for further details).

Remark 2. The Quadratic Program (QP) \([18]\) is feasible for all \(z \in I = \{z = [x^T, \bar{x}^T]^T \in \mathbb{R}^{2n} : h_k(x - \bar{x}) \geq 0, h_x(x) \geq 0\}\) and \(v \in V\).

Remark 3. If Assumptions \([7, 12]\) hold, then the control policy \([19]\) guarantees that Properties \([7, 12]\) are satisfied.

Proof: The proof follows from \([8]\).

B. Discrete Uncertain Model

The CLF-CBF QP \([18]\) computes a control action which constrains the difference between the planned trajectory and the true system into \(S_c\). In this section, we leverage this property to construct an uncertain linear time-invariant model which over-approximates the evolution of the true system from \(x^+(t_k)\) to \(x^+(t_{k+1})\).

First, we define the following reset maps for the error and planning dynamics from \([14]\):

\[
\tilde{x}^+ = \Delta(x^-) = \Delta(x^-) = x^+
\]

\[
e^+ = \Delta(e^-) = 0.
\]

(20)

Basically, the above reset maps set the planning state \(\bar{x}\) equal to the true state \(x\), and consequently the error state \(e = 0\) after each \(\Delta\)th discontinuous transition.

Notice that the planned model is linear for all \(t \in (t_k, t_{k+1}]\), therefore we have that

\[
\bar{x}^+(t_{k+1}) = \bar{A}_{\bar{x}} x(t_k) + B_{\bar{x}}(t_k)
\]

\[
\bar{x}^+(t_k) = \Delta(x^-(t_k)) \subseteq \Delta(\bar{x}^-(t_k) \oplus S_c),
\]

(21)

where the second equation holds from Property \([2]\), the transition matrices are \(\bar{A} = e^{AT} B\) and \(\bar{S}_c\) is a polytope which contains \(S_c\). From \([20]-[21]\) and Assumption \([\ref{assumptions}]\) we have that

\[
x^+(t_{k+1}) = \Delta(x^-(t_{k+1})) \subseteq \Delta(\bar{x}^-(t_{k+1}) \oplus S_c)
\]

\[
= T \bar{x}^+(t_k) + B T v(t_k) \oplus T S_c + g
\]

\[
= T \bar{x}^+(t_k) + B T v(t_k) \oplus T \Delta(S_c).
\]

which over-approximates the evolution of the true system \([14]\) and may be used to check if Property \([3]\) is satisfied, as stated by the following proposition.

Proposition 2. Let Assumptions \([7, 12]\) hold. We define the following control policy

\[
\pi_c : \mathbb{R}^n \rightarrow \mathcal{U}
\]

and the following discrete time uncertain linear system

\[
x^+_d(t_k+1) = T \bar{x}^+_d(t_k) + B T v(t_k) + \bar{w}_d(t_k)
\]

\[
x^+_d(t_0) = x(t_0) = x_0,
\]

(22)

where \(\bar{w}_d(t_k) \in \Delta(S_c). If the for closed-loop system \([22]\) and \([24]\) we have that \(\pi^v(x^+_d(t_k)) \in V\) and \(x^+(t_k) \in X_d \cap S_c, \forall k \in \{0, 1, \ldots\}\), then the closed-loop system \([14]-[19]\) and \([23]\) satisfies Property \([3]\).

Proof: The proof follows from Proposition \([1]\) and Equations \([21]-[22]\). At time \(t_k\), let \(x^+_d(t_k)\) be the state of the closed-loop system \([22]\) and \([24]\) and \(\bar{x}^-(t_k)\) be the planning state of the closed-loop system \([14]-[19]\) and \([23]\). From \([22]\), we have that \(\forall k \in \{0, 1, \ldots\}\) and \(\bar{x} \in \Delta(\bar{x}^- (t_k) \oplus S_c)\) there exist a sequence of disturbances \(\bar{w}_d(t_0), \ldots, \bar{w}_d(t_k)\) such that \(x^+_d(t_{k+1}) = z \in \Delta(\bar{x}^- (t_k) \oplus S_c). Therefore, if \(\pi^v(x^+_d(t_k)) \in V\) and \(x^+_d(t_k) \in X_d \cap S_c, \forall k \in \{0, 1, \ldots\}\), then the closed-loop system \([14]-[19]\) and \([23]\) satisfies Property \([3]\).

C. Model Predictive Control

In this section, we design a Model Predictive Controller that allows us to guarantee high level safety and high level tracking from Properties \([4]\). In particular, we leverage the result from Proposition \([2]\) and we design a robust MPC for the discrete time uncertain linear system \([24]\).

At time \(t_k\) given the state of the system \(x(t_k)\) we solve the following finite time optimal control problem:

\[
\min_{\nu_t} \sum_{k=t}^{t+N} ||x_{k|t} - x_g||_Q + ||v_{k|t}||_R + ||x_{t+N|t} - x_g||_Q_f
\]

s.t. \[
x_{k+1|t} = T(\bar{A} + B K)x_{k|t} + B v_{k|t}
\]

\[
x_{t|t} = \Delta(x^-(t))
\]

\[
x_{k|t} \in X_d \cap S_c \oplus E_k, v_{k|t} \in V \oplus K E_k
\]

\[
x_{t+N|t} \in X_F \cap E_{t+N}, \forall k \in \{t, t+1, \ldots\}
\]

(25)

where \(K\) is a stabilizing feedback gain, \(||x||_Q = x^T Q x\), \(E_{k+1} = T(\bar{A} + B K) E_k \oplus \Delta(S_c)\) and \(E_0 = 0\). The above control problem computes a sequence of open loop actions \(\nu_t = [v_{t|t}, \ldots, v_{t+N|t}]\) which robustly steer system \([24]\).
from the current state \( x(t_k) \) to the terminal set \( X_F \), while minimizing the nominal cost and robustly satisfying state and input constraints [19]. Let \( v_*^t = [v_*^t[1], \ldots, v_*^{t+N}|] \) be the optimal solution and \([x_*^t[1], \ldots, x_*^{t+N}[^t]\) the associated optimal trajectory, then the MPC policy is

\[
\pi^u(x(t)) = v_*^t + Kx_*^t. \tag{26}
\]

**Assumption 3.** The terminal constraint set \( X_F \subset X_d \) in (25) is a robust positive invariant set for the uncertain system in closed loop with the policy \( \kappa(x) = Kx \).

**D. Closed-loop Properties**

In this section, we show that Properties [14] hold for the closed-loop system (15)-(19) and (26) and the sets in (16). Therefore, the closed-loop system satisfies state and input constraints (3).

**Theorem 2.** Consider system (15) in closed-loop with (19) and (26). Let Assumptions [17] hold. Assume that problem (15) is feasible at time \( t = 0 \), then the closed-loop system (15), (19) and (26) satisfies state and input constraints (3) for all time \( t \geq 0 \).

**Proof:** Notice that from Proposition 1 and equation (20), we have that the closed-loop system satisfies Properties 1.2 and 4. Moreover from standard MPC arguments [19], [20], we have that the MPC policy (26) guarantees that the uncertain closed-loop system (24) and (26) evolves inside \( X_d \cap \mathcal{S}_x \) and \( \pi^u(x(t_k)) \in \mathcal{V} \) for all \( k \in \{0, 1, \ldots\} \) (thus Property 3 hold). Concluding, Properties 1.4 are guaranteed for the closed-loop system (15), (19) and (26) and state and input constraints (3) are satisfied for all time \( t \geq 0 \).

**V. Simulation Results**

We use the proposed strategy to steer a segway to a goal state, as shown in Figure 3. The state of the system are the position \( p \), the velocity \( v \), the rod angle \( \phi \) and the angular velocity \( \omega \). The control action is the voltage commanded to the motor and the equations of motion used to simulate the system can be found in [7, Section IV.B]. The nominal model is obtained using a small angle approximation and the MPC is implemented for \( Q = \text{diag}(0.1, 10^{-3}, 10^{-3}, 10^{-2}), R = 1, Q_F = \text{diag}(100, 100, 100, 200), \mathcal{V} = \{v \in \mathbb{R} : ||v||_{\infty} \leq 20\} \) and \( K = [0, -7.3989, -10.435, -3.7039] \). Finally, we implemented the CLF-CBF [18] for \( \mathcal{S}_e = \{e \in \mathbb{R}^n : e^TQ_e e \leq 1\} \) with \( Q_e = \text{diag}(1/0.2^2, 1/0.1^2, 1/0.05^2, 1/0.01^2) \), \( \mathcal{X}_e = \mathbb{R}^n \) and \( \mathcal{U} = \mathbb{R} \).

**A. Unconstrained Example with Low Frequency Update**

In this example, we run the high level MPC planner at 2Hz, we set \( X_d = \mathbb{R}^n \) and the MPC horizon \( N = 10 \). Figure 3 shows the closed-loop trajectories for the proposed strategy, a linear MPC and nonlinear MPC policies, which are implemented Euler discretizing the system at 100Hz and 20Hz for prediction horizons \( N_{100Hz} = 500 \) and \( N_{20Hz} = 100 \), respectively. All strategies plan the desired trajectory over a receding time window of 5 seconds. We notice that the linear MPC overshoots the goal state and the nonlinear MPC discretized at 20Hz oscillates before reaching the target state. On the other hand, the proposed strategy performs similarly to the high frequency nonlinear MPC (discretized at 100Hz with prediction horizon \( N_{100Hz} = 500 \)), while being implemented with a 2Hz model update rate, a prediction horizon \( N = 10 \) and solving convex optimization problems. This examples shows the advantage of the proposed multi-rate architecture, where the high level control action is updated at a lower frequency than the low level input command, as shown in Figure 5.

![Fig. 3. The goal of the controller is to steer the segway to a goal state while keeping the rod upright. Furthermore, we reported snippets of the state trajectory from Section V-A at 0.5s, 1.5s and 2s.](image)

**B. Constrained Example with High Frequency Update**

In this example, we run the high level MPC planner at 10Hz, we set \( X_d = \mathbb{X} = \{x = [p, v, \theta, \omega]^T \in \mathbb{R}^n : |\theta| \leq 0.78\} \) and the MPC horizon \( N = 10 \). We compare the proposed strategy with a linear MPC and a nonlinear MPC where the system dynamics are Euler discretized at 10Hz. Also
for the linear and nonlinear MPC, we use the constraint tightening from (25). Figure 6 shows that when the high frequency input from the low level controller is not used, the closed-loop system violates the state constraints. We underline that constraint satisfaction for nonlinear MPC policies can be guaranteed using the approaches from [14]–[17]. However, this example shows the advantage of using the high frequency low level controller to reduce the tracking error. Indeed, when the low level controller is not employed, the constraint tightening from (25) is not sufficient to guarantee constraint satisfaction, both when linear and nonlinear models are used for planning.

VI. CONCLUSIONS

In this paper, we presented a multi-rate control architecture, where the high level planner and the low level controller run at different frequencies. First, we introduced sufficient conditions which guarantee recursive constraint satisfaction for the closed-loop system. Afterwards, we presented a controller design which leverages control barrier functions and MPC policies. Finally, we demonstrated the effectiveness of the proposed approach on a numerical example. Future work will be devoted to realizing these ideas on hardware.
