Abstract

Background

The bone marrow niche supports hematopoietic cell development through intimate contact with multipotent stromal mesenchymal stem cells; however, the intracellular signaling, function, and regulation of such supportive niche cells are still being defined. Our study was designed to understand how G protein receptor kinase 3 (GRK3) affects bone marrow mesenchymal stem cell function by examining primary cells from GRK3-deficient mice, which we have previously published to have a hypercellular bone marrow and leukocytosis through negative regulation of CXCL12/CXCR4 signaling.

Methods

Murine GRK3-deficient bone marrow mesenchymal stromal cells were harvested and cultured to differentiate into three lineages (adipocyte, chondrocyte, and osteoblast) to confirm multi-potency and compared to wild type cells. Immunoblotting, modified-TANGO experiments, and flow cytometry were used to further examine the effects of GRK3 deficiency on bone marrow mesenchymal stromal cell receptor signaling. Microcomputed tomography was used to determine trabecular and cortical bone composition of GRK3-deficient mice and standard ELISA to quantitate CXCL12 production from cellular cultures.

Results

GRK3-deficient, bone marrow-derived mesenchymal stem cells exhibit enhanced and earlier osteogenic differentiation in vitro. The addition of a sphingosine kinase inhibitor abrogated the osteogenic proliferation and differentiation, suggesting sphingosine-1-phosphate receptor signaling was a putative G-protein coupled receptor regulated by GRK3. Immunoblotting showed prolonged ERK1/2 signaling after stimulation with sphingosine-1-phosphate in GRK3-deficient cells, and modified-TANGO assays suggested the involvement of β-arrestin-2 in sphingosine 1 phosphate receptor internalization.

Conclusions

Our work suggests that GRK3 regulates sphingosine-1-phosphate receptor signaling on bone marrow mesenchymal stem cells by recruiting β-arrestin to the occupied GPCR to promote internalization, and lack of such regulation affects mesenchymal stem cell functionality.

Introduction

Mesenchymal stem cells are multipotent stromal cells that possess the ability to differentiate into mesodermal tissues, such as chondrocytes, adipocytes, and osteocytes (1). Mesenchymal stem cells that reside within the bone marrow microenvironment, often referred to as bone marrow niche mesenchymal stem cells (BmMSCs), secrete high levels of chemokine C-X-C Motif Chemokine Ligand 12 (CXCL12), which can bind to G protein-coupled receptor (GPCR) C-X-C Chemokine Receptor Type 4 (CXCR4) on
hematopoietic stem and progenitor cells (HSPCs) to affect their growth and development (2, 3). We previously published that mice deficient in *G protein-coupled receptor kinase 3 (Grk3)*, an intracellular kinase that negatively regulates GPCRs, have a hypercellular bone marrow comprised of increased Lin-Sca1+ c-Kit+ (LSK) HSPCs and selective downstream committed progenitors and an increase of total white blood cells in the peripheral blood (leukocytosis) compared to wildtype (WT) mice (4). GRK3 deficiency affects CXCR4 regulation on hematopoietic cells in mice (4) and humans (5); however, the regulatory effects of GRK3 on BmMSC function and BmMSC GPCRs are not well defined. Due to the importance of BmMSCs on HSPC biology, we wished to better clarify how GRK3, which is expressed on BmMSCs (6), affects their function and through which GPCR these effects may be regulated.

We observed *Grk3/-* BmMSCs have enhanced osteogenic differentiation, higher levels of CXCL12, and increased proliferation. Although we have previously published that global deficiency of GRK3 leads to bone marrow hypercellularity and leukocytosis in mice (4), micro-CT of cortical and trabecular bone did not show substantial clinical differences in bone density measurements. Accumulating evidence supports that phospholipid sphingosine-1-phosphate (S1P) affects mesenchymal stem cell function (7) in osteogenic differentiation (8-10) and proliferation (11, 12), thus we examined GRK3-dependent S1PR antagonism, signaling, and β-arrestin-2 recruitment to determine the interplay between these protein interactions in BmMSC biology. Establishing functional relationships in chemokine receptor signaling of stem cells relevant to the bone marrow niche may further facilitate mechanistic understanding of stem cell biology and potential therapeutic targeting of stem cells for the treatment of cancer, autoimmunity, and immunodeficiency disorders.

**Materials And Methods**

**Animals.** C57BL/6 WT and *Grk3/-* age-matched (8-12 week-old) mice were used under standard IACUC-approved protocols in the AAALAC-accredited vivarium of UNC, and care of animals was in accordance with institutional guidelines. The *Grk3/-* mouse strain was provided by Dr. Robert J. Lefkowitz (Duke University) and backcrossed >12 generations on the C57BL/6 background. The line is re-derived every 1-2 years to prevent genetic drift from the C57/BL/6 strain.

**Bone marrow-derived mesenchymal stem cell isolations.** BmMSC were isolated from RPMI-flushed femurs and tibias of two male mice and cultured in complete isolation media containing RPMI (Corning, 10040CV) with 10% fetal bovine serum (FBS, Atlanta Biologicals, S12450), 10% horse serum (HS, HyClone, SH30074.03), 1% 100 IU/mL penicillin G/100 µg/mL streptomycin (P/S, Corning, 30-002-Cl), and 12 µM final concentration of L-Glutamine (Corning, 25-005-Cl), as similar methodologies have been previously described (13-15). BmMSC expansion was in complete expansion media (CEM) containing IMDM (Gibco, 12440-053), 10% FBS, 10% HS, 1% P/S, and 12 µM final concentration of L-Glutamine (14, 15), which was followed by hematopoietic CD45 (Stem Cell Technologies, 19771) and CD11b (Miltenyi, 130-049-601 or 130-093-634) depletion, as recommended by (13), via magnetic negative selection at early passages 1-3. BmMSCs were passaged at 70-80% confluency and used for experiments at passages 4-15.
**Chondrogenic, adipogenic, and osteogenic differentiation.** *Chondrogenic differentiation.* BmMSCs were suspended in CEM at $1.6 \times 10^7$ viable cells/mL. Micromasses were made by adding 5 µL droplets of the cell suspension onto a 6-well plate and given 3-4 hours to attach. Chondrogenic media (Gibco StemPro® Chondrogenesis Differentiation Kit, A10071-01) supplemented with penicillin streptomycin was added to each well and incubated for 21 days. Cells were fixed with 10% formalin and stained using Alcian Blue.

*Adipogenic differentiation.* BmMSCs were plated at $1 \times 10^5$ cells/well of a 6-well plate in CEM supplemented with 50 µM indomethacin, 5 µg/mL insulin, and 0.1 µM dexamethasone. Cells were fixed with 10% formalin and stained using Oil Red O. *Osteogenic differentiation.* BmMSCs were plated at $1 \times 10^5$ cells/well of a 6-well plate in CEM supplemented with 50 µg/mL ascorbic acid and 20 mM β-glycerophosphate. Cells were fixed with 10% formalin and stained using Alizarin Red. For SKI-treated osteogenic differentiation, BmMSCs were plated at $2 \times 10^4$ cells/well in a 24-well plate in CEM, and osteogenic differentiation was induced after an overnight rest. Cells were treated with sphingosine kinase inhibitor 2 (SKI, Cayman Chemical, 10009222) at a final concentration of 5 µM or vehicle (DMSO). Fresh media changes occurred every third day using CEM plus SKI or vehicle. Cells were fixed with 10% formalin and stained using Alizarin Red stain for analysis. Images were captured using the Olympus 1X-81 microscope and MetaMorph software.

**Bone marker mRNA expression (qRT-PCR).** Total RNA from BmMSCs undergoing osteogenic differentiation was prepared using the RNeasy Mini/ Plus kit (Qiagen) according to manufacturer's instructions. Reverse transcriptase cDNA synthesis was performed using iScript cDNA synthesis kit (Bio-Rad, 170-8891). qRT-PCR was performed in duplicate (SYBR® Green, Bio-Rad, 172-5261) and normalized to housekeeping gene IDUA. Mean fold change of alkaline phosphatase was determined by $-2^{\Delta \Delta Ct}$ with WT day 0 as control. Primers utilized for qRT-PCR were Alkaline Phosphatase forward: AAG GCT TCT TCT TGC TGG TG, Alkaline Phosphatase reverse: GCC TTA CCC TCA TGA TGT CC; IDUA forward: GCA TCC AAG TGG GTG AAG TT and IDUA reverse: CAT TGA GCA GGT CCG GAT AC.

**ELISA.** BmMSCs were plated at $1 \times 10^5$ cells/well of a 6-well plate in CEM and rested overnight for attachment before supernatant collections began at baseline (day 1) and each subsequent collection. Supernatants of undifferentiated BmMSC monolayers were collected and analyzed for CXCL12 protein using the CXCL12 DuoSet ELISA kit (R&D Systems, DY460), as per instructions.

**Micro-computed tomography (µCT).** For 8-12 week-old mice, µCT imaging was used to analyze the trabecular bone morphology at the distal femur at 12 micron resolution. The metaphyseal region of the distal femur was scanned beginning 720 microns proximal to the growth plate and extending 1500 microns towards the diaphysis of the femur. An automatic script was used to analyze the region of interest to separate the trabecular and cortical regions of the bone and quantify bone morphology. Trabecular analysis includes quantification of BV/TV (bone volume/total volume). For 17-20 month-old aged mice, µCT imaging morphology (VivaCT80, Scanco Medical, Basserdorf, Switzerland) was used to analyze the trabecular bone. Briefly, metaphysis region was selected for 100 slices under the femur growth plate. Trabecular analysis includes quantification of BV/TV. Analyses were conducted at 12 µm
slice increment with an integration time of 300 ms, a current of 145 mA, and an energy setting of 55 kV. The threshold was chosen using 2D evaluation of several slices in the transverse anatomic plane so that mineralized bone was identified but surrounding soft tissue was excluded.

**Cellular proliferation.** Proliferation of 5x10⁴ BmMSCs/well of a 6-well plate was analyzed after exogenous CCK-8 (Dojindo Molecular Technologies) was added to each well at the indicated timepoints. Absorbance was measured after 3-hour incubation using the Promega Glomax® Multi + Detection System. Data were analyzed by deducting background (media and CCK-8) absorbance from raw absorbance reads. For S1P studies, BmMSCs were plated at 1x10⁴ cells/well in a 24-well plate and treated with SKI at a final concentration of 5 µM.

**Immunoblotting.** BmMSCs were plated in CEM at 2.25x10⁵ cell density in a 6-well plate and incubated overnight. DPBS rinsed cells were rinsed three times with IMDM containing 20% charcoal-stripped FBS (to remove serum S1P) and 1% P/S, and incubated at 37°C for 15 minutes. Fresh media was added, and BmMSCs were stimulated with 1 µM S1P for indicated timepoints. Unstimulated BmMSCs served as 0 minute timepoint control. Following stimulation with S1P, BmMSCs were rinsed with DPBS and lysed in cold HBSS + 1% TritonX100 lysis buffer containing protease inhibitors (1 mM PMSF, 1 µg/mL aprotinin, 1 µg/mL pepstatin, and 1 µg/mL leupeptin) and phosphatase inhibitors (5 mM NaF and 2 mM NaVO₄). All WT and Grk3-/ BmMSC lysates were normalized via Bicinchoninic acid (BCA) assay, and 6 µg of total protein in laemmli sample buffer (non-reducing) was freshly loaded onto AnyKD Mini-PROTEAN®TGX precast protein gel (Bio-Rad, 4569036). Gels were run at 100V for 1.5 - 2 hours in 1XTris/Glycine SDS buffer. Proteins were transferred overnight at 4°C onto nitrocellulose membrane in Tris base (25 mM)/Glycine (192 mM) transfer buffer containing 20% methanol. The membrane was blocked in 3% fatty-acid free BSA in TBS plus 0.1% Tween-20 (TBS/T) for 2 hours at 25°C and incubated with primary antibody 1:2,000 phospho-p44/42 MAPK or 1:2,000-3,000 p44/42 MAPK (Cell Signaling Technologies, 4370/4695) overnight at 4°C, or 1:10,000 GAPDH (Trevigen, 2275-PC-100) for 2 hours at 4°C. The membrane was washed three times for 10 minutes in TBS/T, incubated with secondary antibody 1:5,000 anti-rabbit IgG HRP (Cell Signaling Technologies, 7074) for 1 hour at 25°C, and washed twice for 10 minutes in TBS/T and once in TBS. Detection was performed via ECL Prime or ECL Select (GE Healthcare, RPN2232/ RPN2235) and imaged on GeneSys image acquisition software. Densitometry was obtained by measuring ratio of phospho-ERK (pERK) over total ERK using Image J software.

**β-arrestin recruitment assay.** GRK recruitment of β-arrestin-2 to the S1PR1 carboxy-terminus was measured using agonist-stimulation in a modified-TANGO assay, as previously reported (16). HTLA cells were transfected with a S1PR1-TCS-tTA receptor construct after removing the V2 vasopressin sequence to prevent nonspecific β-arrestin recruitment to the wildtype S1PR1. GRK over-expression was achieved via plasmids: GRK2 pcMyc_LIC and GRK3 pcMyc_LIC, and utilized a separate expression vector encoding yellow-fluorescent protein (YFP) that was simultaneously transfected to serve as a transfection control. HTLA cells were transiently transfected with 6.5 µg of total plasmid DNA (3 µg of S1P-Tango, 0.5 µg of YFP, and either 3 µg of empty-vector control, GRK2, or GRK3) via calcium-phosphate precipitation. Transfection efficiency was determined by YFP epifluorescence to be consistently >70% at 24 hours post-
transfection. Cells were serum starved and then stimulated with S1P ligand at varied concentrations up to 1 µM. BriteGlo reagent (Promega, Madison, WI, USA) was added for luminescence detection via Promega Glomax® Multi + Detection System (0.5 sec/ well). Raw data were normalized by subtracting background for each independent run and setting the lowest concentration of the control condition at 0% and highest concentration at 100%.

**S1PR1 internalization assay.** BmMSCs cultured in CEM were rinsed with DPBS and incubated in serum-free CEM (SFM) for 2.5 hours. BmMSCs were detached using Accutase® (Sigma, A6964), rinsed once with cold SFM containing 5% charcoal-stripped FBS (to remove serum S1P), and resuspended in cold DPBS. \(1 \times 10^5\) BmMSCs were stimulated with 1 µM S1P ligand in 100 µL FACS buffer (DPBS1X + 0.2% fatty acid free BSA + 0.1% sodium azide) at specific timepoints. Unstimulated BmMSCs served as 0 minute timepoint control. S1PR1 internalization was halted with 2 mL of ice cold FACS buffer and sample tubes were placed on ice. BmMSCs were stained for Sca1 (eBioscience clone: D7, APC-conjugated) and S1PR1 (R&D Systems clone: 713412, PE-conjugated) for 30 minutes on ice in 100 µL FACS Buffer, rinsed, and analyzed by flow cytometry.

**Statistical analyses.** All data were graphed utilizing GraphPad Prism v.7 and statistically evaluated using GraphPad Prism v.7 or Microsoft Office Excel program. Taking into consideration time and strain (WT and Grk3-/-), the bone marker qRT-PCR, CCK-8 proliferation, and S1PR1 internalization was statistically analyzed using a RM two-way ANOVA with Sidak’s multiple comparison test, a method preferred over Bonferroni due to increased power (17, 18). Similarly, taking into consideration time and strain (WT and Grk3-/-) but with multiple treatment groups, the SKI-treated CCK-8 proliferation was analyzed using a RM two-way ANOVA with Tukey’s multiple comparison test for pairwise comparisons (17, 19). Student’s t-test compared two independent groups (WT and Grk3-/-) for the CXCL12-detection ELISA, microcomputed tomography data, and western blot densitometry. Taking into consideration three independent groups (empty vector, GRK2, and GRK3), the β-arrestin recruitment assay was analyzed by one-way ANOVA with Dunnett’s multiple comparison test, which compared each group to the control (empty vector) (17, 20).

**Results**

**GRK3-deficient BmMSCs have enhanced osteogenic differentiation.** In our previous publication, we observed Grk3-/- mice had increased HSPC numbers compared to WT mice (4). Since it is well established that bone marrow stromal cells enhance hematopoiesis (21-26), we aimed to test whether there were differences between Grk3-/- and WT murine stromal BmMSCs that could contribute to this phenotype. BmMSCs isolated from WT and Grk3-/- mice adhered to culture plastic, underwent differentiation into tissue-specific lineages to ensure multipotency (Fig. 1A), and lacked expression of CD45 and CD11b (hematopoietic cell markers) and consistently expressed mouse mesenchymal stem cell markers Sca1, CD106, CD73, CD44, CD29 (Additional Files Fig. S1). During differentiation analysis, we observed no substantial differences between WT and Grk3-/- BmMSC chondrogenic or adipogenic differentiation cultures. However, we observed enhanced and earlier osteogenic differentiation in Grk3-/- BmMSC cultures in comparison to WT cultures, as demonstrated by positive alizarin red stain (Fig. 1B)
and higher mRNA expression levels of alkaline phosphatase (ALP), a marker of osteoblast differentiation that peaks near day 14 (Fig. 1C) (27, 28). We noticed the enhanced osteogenic differentiation phenotype was reproducible in four separate isolations. To further ensure there was no isolation differences between WT and Grk3-/BmMSCs that may induce such a phenotype, we utilized shRNA to knockdown GRK3 (GRK3-KD) from WT BmMSCs and induced multipotent differentiation, which again showed the identical phenotype of enhanced osteogenic differentiation in GRK3-KD BmMSCs in comparison to non-target (NT) control BmMSCs (Additional Files Fig. S2).

**GRK3-deficient BmMSC cultures have higher levels of CXCL12.** BmMSCs, CXCL12-abundant reticular cells, and pre-osteoblasts isolated from bone marrow secrete CXCL12 (22, 23), an essential chemokine for HSPC development and/or function. Since we published that Grk3-/ mice had increased HSPCs in vivo (4), we tested whether or not there may be differences in HSPC growth factor CXCL12 between WT and Grk3-/BmMSCs ex vivo. Our data reveal that Grk3-/BmMSC cultures had higher CXCL12 levels at baseline and after subsequent days in culture in comparison to WT BmMSC (Fig. 2A).

**GRK3 deficiency increases BmMSC proliferation ex vivo.** Due to the enhanced detection of CXCL12 in Grk3-/BmMSC culture, we wanted to further investigate whether this was the result of enhanced secretory function or as a proliferation response. Cell counting kit-8 (CCK-8) quantitates proliferation by absorbance detection of increased formazan dye production from viable cells. Using this assay of cellular proliferation, we show that Grk3-/BmMSCs have more proliferation in comparison to WT BmMSCs (Fig. 2B).

**GRK3 deficiency does not affect mature bone formation in vivo.** Because Grk3-/ BmMSC osteogenic differentiation and proliferation are increased ex vivo, we investigated whether or not GRK3 deficiency affected mature bone development and osteoporosis in vivo. We performed microcomputed tomography (µCT) femoral bone analyses on WT and Grk3-/ young (8-12 week) and aged (17-20 month) mice. No statistical differences in the trabecular bone volume fraction of Grk3-/ young or aged mice were observed between genotypes (Fig. 3A-D).

**Inhibition of S1P reduces the enhanced osteogenic differentiation and proliferation phenotype of Grk3-/BmMSCs.** Since GRK3 regulates signaling of cell-surface expressed GPCRs (6), we next aimed to identify the putative GPCR that could be contributing to the enhanced Grk3-/BmMSC phenotypes of osteogenic differentiation and proliferation. Since we and others have demonstrated that BmMSCs secrete CXCL12 (22, 23), that GRK3 regulates CXCR4 in other cell types (4, 5, 29), and that GRK3 regulation of CXCR4 impacts bone marrow hematopoietic cell functionality (4, 30), we proposed CXCL12 may be acting via an autocrine CXCL12/CXCR4 signaling loop on BmMSCs. However, neither agonist stimulation nor antagonist inhibition of CXCR4 signaling affected the increased Grk3-/BmMSCs proliferation that we observed (Additional Files Fig. S3).

Accumulating evidence supports phospholipid S1P affects mesenchymal stem cell function (7), specifically in osteogenic differentiation (8-10) and proliferation (11, 12). Since S1P binds to GPCR S1P receptors (S1PR), we next hypothesized that GRK3 was negatively regulating S1PR signaling, leading to
functional outcomes of enhanced BmMSC proliferation and osteogenic differentiation. To test this hypothesis, we had to address that (1) S1P is readily available in the BmMSC culture media due to the naturally high presence in fetal bovine and horse serum (31) and that (2) murine BmMSCs secrete S1P (32), similarly to CXCL12. Therefore, to effectively neutralize S1P in culture, we utilized a sphingosine kinase inhibitor (SKI), which reduces the conversion of sphingosine to active ligand S1P. We also verified that WT and Grk3-/BmMSCs had comparable sphingosine kinase activity before manipulation of this pathway (Additional Files Fig. S4). Titration of SKI to an optimized dose of 5 µM reduced both Grk3-/osteogenic differentiation (Fig. 4A) and proliferation (Fig. 4B) to comparable levels with WT BmMSCs, suggesting S1PR, and not CXCR4, has a role in the enhanced phenotypes.

**Grk3-/BmMSCs have enhanced ERK1/2 signaling after S1P stimulation.** The extracellular related kinase (ERK) signaling pathway has been linked to both mesenchymal stem cell (33) and pre-osteoblastic cell line (34) osteogenic differentiation, as well as mesenchymal stem cell proliferation (12); therefore, we hypothesized ERK signaling may be enhanced in Grk3-/BmMSCs with S1P stimulation. We show via densitometry ERK1/2 early signaling at 0, 1, and 5 minutes is comparable between WT and Grk3-/BmMSCs (Fig. 5A, B); however, during late signaling, while WT signaling wanes after 30 minutes, Grk3-/BmMSCs show sustained signaling still at 60 minutes (Fig. 5A, C).

**GRK3 recruits β-arrestin to the C-terminus of S1PR1 and affects S1PR1 internalization.** While BmMSCs express S1PRs1-3 (35-37), the intracellular signaling, function, and regulation of each specific receptor on BmMSCs is still being defined. Recent studies have shown stimulatory BmMSC function through ligation of S1PR1 and S1PR3 in contrast to inhibition of function after stimulation through S1PR2 (36). We hypothesized our enhanced GRK3-regulatory phenotype may be mediated via S1PR1, since our Grk3-/BmMSCs phenotype showed enhanced proliferation and prolonged ERK1/2 signal activation, analogous to previously reported S1PR1 activation in adipose-derived mesenchymal stem cells (12). S1PR1 was also clearly detected on WT and Grk3-/BmMSCs by protein lysate analysis and flow cytometry (Additional Files Fig. S5A, B).

We hypothesized that GRK3 could be involved in S1PR1 β-arrestin recruitment—a protein necessary for GPCR internalization and another pathway of GPCR regulation in addition to receptor desensitization. Using the modified-TANGO assay (16, 38) with GRK2 as a positive control (39), we demonstrated GRK3 recruits β-arrestin to the C-terminus of S1PR1 (Fig. 6A). We next hypothesized that receptor internalization was an additional means of GRK3/S1PR1 regulation, and thus S1PR1 internalization would be impaired in Grk3-/BmMSCs. In S1P-activated receptor internalization assays, S1PR1 surface receptor expression by flow cytometry was prolonged over time in Grk3-/BmMSCs compared to controls (Fig. 6B), suggesting a defect in β-arrestin-mediated internalization.

**Discussion**

Mesenchymal stem cells are under active investigation for use in regenerative medicine and cell therapy; therefore, there is an essential need for better cellular characterization and understanding of their
signaling, function, and regulation (40-42). Challenges within the field include *ex vivo* expansion studies utilizing different tissue-derived sources of cells, growth media conditions, serum sources and lots, seeding densities, and sample variations (40, 43), which can be potential confounders in interpreting data. To reduce such confounders, we utilized media previously published to best support BmMSCs from C57BL/6 mice (14), maintained the same serum sources and lots throughout all studies, seeded and cultured cells at comparable densities, and minimized sample-variation findings by design and testing of several different BmMSC isolations from WT and Grk3-/− mice.

Here, we demonstrate that BmMSCs deficient in *Grk3* more readily differentiate into osteoblasts upon osteogenic supplementation (Fig. 1A-C, Additional Files Fig. S2), produce more CXCL12 (Fig. 2A), and proliferate more *ex vivo* (Fig. 2B). We hypothesize that these *in vitro* findings may additionally contribute toward mechanisms underlying the enhanced hematopoiesis phenotype that we observed in the *Grk3*-/− mouse (4) and appear to be less relevant in osteoporosis or mature bone development (Fig. 3). Previous studies have demonstrated depletion of CXCL12 or total numbers of mesenchymal stem cells decrease the bone marrow hematopoietic stem cell pool and repopulating activity (22-24). Thus, we might conclude the enhanced numbers of HSPCs observed in the *Grk3*-/− mouse bone marrow (4) could be attributed at least in part to the *Grk3*-/− BmMSC enhanced phenotypes described here. However, we recognize that selective *Grk3* gene targeting of mesenchymal stem cells and/or osteoblasts *in vivo* would be necessary to definitively conclude this – the timing of which may prove challenging in targeting which stage of stem cell development is most relevant for *Grk3* expression. These are the goals of future studies, as opposed to the focus of this initial characterization of *Grk3*-/− BmMSCs and identification of candidate regulatory GPCRs.

*Grk3*-/− BmMSC cultures had higher levels of CXCL12 at baseline upon equal seeding densities, and one interpretation is that *Grk3*-/− BmMSCs have an enhanced CXCL12 secretory function, such as has been described of CXCL12-abundant reticular stromal cells in the bone marrow (22). However, our study also detected enhanced proliferation of *Grk3*-/− BmMSCs at later timepoints (Fig. 2B). This suggests the levels of CXCL12 detection at most time points are likely due to increased number of *Grk3*-/− BmMSCs in culture.

Neither young (8-12 week-old) nor aged (17-20 month-old) *Grk3*-/− mice show enhancement of mature trabecular bone formation *in vivo* (Fig. 3A-D). Possible explanations of this finding may be attributed to our *Grk3*-/− conventional knockout mouse model, where there may be other compensatory cellular interactions at play. Importantly, *Grk3* expression levels have been found to be either undetectable or minimally expressed in osteoblastic cell lines (44). This physiologic downregulation of *Grk3* in more mature osteoblasts, as opposed to precursor stem cells, could also explain why differences were not observed in trabecular bone *in vivo*.

To test whether GRK3 may regulate S1P-stimulated S1PR, our studies utilized sphingosine kinase inhibitor (SKI) to efficiently reduce the active S1P ligand in extended time-course studies and thereby block ligand activation for all S1PR family members expressed on BmMSCs (Fig. 4 and Additional Files
Fig. S5A and 5B). These results did show that the enhanced proliferation and osteogenic differentiation of Grk3-/BmMSCs can be reduced to WT levels with effective removal of the S1PR ligand. Of note, we also tested specific S1PR antagonism targeting S1PR1 and S1PR3 (45). However, we observed BmMSC cellular toxicity in our extended time-course studies while using similar concentrations of vehicle (DMSO) alone that was present in the solubilized S1PR1 and S1PR3 antagonist (VPC23019, Cayman Chemical) group, making this data of receptor-specific antagonism not interpretable. Consequently, our culture studies with BmMSCs and S1PR antagonism could not identify which S1PR subtype expressed on BmMSCs elicit the enhanced functionality due to concerns about cell viability and experimental rigor.

GRK3 is a ubiquitously expressed kinase that regulates a number of GPCR, including parathyroid hormone receptor (PTH-R) (46). Although our cellular characterization studies suggest loss of GRK3 function affects S1PR signaling leading to enhanced BmMSC functionality ex vivo, we considered GRK3 regulation of parathyroid hormone/parathyroid hormone receptor (PTH/PTH-R), since PTH/PTH-R has been linked to osteoblast differentiation and enhanced hematopoiesis (47, 48). However, ligand PTH is not readily available in ex vivo cultures, and PTH-R was absent from a RNA-seq database evaluation of readily expressed GPCRs on (human) BmMSCs (ENCODE GEO accession: GSE90273) (49). Alternatively, the RNA-seq database showed S1PR expression on BmMSCs, and it is well established that S1P is readily available in horse and fetal bovine serum (i.e.: BmMSC culture media) (31).

Contrary to our finding, Hosogane et al. proposed CXCL12 regulates bone morphogenetic protein 2-induced osteogenic differentiation of primary mesenchymal stem cells demonstrated in part by treatment with AMD3100 (CXCR4 antagonist) to show reduction of osteogenic differentiation (50). Our functional tests with CXCL12 stimulation or CXCR4 signaling inhibition with AMD3100 resulted in no effect (Additional Files Fig. S3). One explanation for differences between our data are that CXCR4 is detected on human BmMSCs (51, 52) but less so on murine BmMSCs cultured in vitro (53). Other possible explanations for outcome differences may be that the Hosogane et. al MSC cultures were different based on isolation technique, cell surface marker expression, differences in AMD3100 concentration, or a combination of these variables.

To investigate whether the enhanced functionalities of Grk3-/BmMSCs were due to changes in S1PR signaling, we tested the ERK signaling pathway since previous studies suggest ERK activation promotes both mesenchymal stem cell (33) and pre-osteoblastic cell line (34) osteogenic differentiation, as well as mesenchymal stem cell proliferation (12). Our previous work has shown GRK deficiency elicits sustained ERK signaling due to prolonged GPCR surface expression and failure to desensitize ligand-GPCR stimulation (4); therefore, we hypothesized loss of GRK3 in BmMSCs may elicit sustained ERK activation through S1P/S1PR ligation. Our results show that stimulation with S1P prolongs Grk3-/BmMSC ERK1/2 signaling (Fig. 5), and thus suggest S1P-ligand induced signaling of Grk3-/BmMSCs may promote enhanced cell functions mediated through the ERK1/2 signaling pathway.

S1PR1 and S1PR3 have been shown to stimulate BmMSC function (36), but S1PR1-mediated enhanced proliferation has been demonstrated in adipose-derived MSCs (12). Thus, we focused our receptor
signaling regulation studies on S1PR1 to determine whether GRK3 enhances recruitment of β-arrestin-2, a protein necessary for GPCR internalization and another pathway of GPCR regulation in addition to receptor desensitization by GRKs. Previous studies have shown GRK2, which shares high homology with GRK3, phosphorylates the C-terminus of S1PR1 (54, 55), and activated S1PR1 recruits β-arrestin-2 for receptor internalization (55, 56). Furthermore, cells deficient in GRK2 have high levels of surface S1PR1 (39). Consequently, we compared GRK2 as a positive control for our modified-TANGO assay. We demonstrate GRK3 enhances β-arrestin-2 recruitment to the C-terminus of S1PR1, as does GRK2 (Fig. 6A). Furthermore, BmMSCs deficient in GRK3 had decreased S1PR1 internalization (i.e. more surface expression) (Fig. 6B). Thus, we propose loss of GRK3 affects S1PR1 regulation on the BmMSC by impairing S1PR desensitization, prolonging S1PR internalization leading to enhanced surface receptor expression and ligand activation with S1P that in turn sustains late-phase ERK1/2 activation (Fig. 5).

**Conclusions**

In summary, our study reveals how Grk3-/−-BmMSCs have enhanced functions of osteogenic differentiation and proliferation that is attributed to altered S1P/S1PR (Fig. 7A). We demonstrate GRK3 recruits β-arrestin-2, a protein necessary for receptor internalization, to the C-terminus of S1PR1, and BmMSCs lacking GRK3 regulation have impaired S1PR1 internalization and prolonged ERK1/2 signaling (Fig. 7B). Our work suggests GRK3 regulates S1PR on BmMSCs, and we propose lack of such regulation affects BmMSC functionality.

Declarations

Ethics approval and consent to participate: Mice were used under standard IACUC-approved protocols in the AAALAC-accredited vivarium of UNC, and care of animals was in accordance with institutional guidelines.

Consent for publication: not applicable

Availability of data and materials: the data obtained in these studies is contained within the manuscript and supplementary files.

Competing interests: the authors declare that they have no competing interests.

Funding: funding was provided by the National Heart, Lung, and Blood Institute (NHLBI) of the National Institutes of Health under award number F31HL128029, the National Institute of Arthritis and Musculoskeletal and Skin Diseases (NIAMS) under award number R03AR059286, and the National Institute of Allergy and Infectious Diseases (NIAID) under award number K08AI070684.

Authors’ contributions: JMB was responsible for conception and design, financial support, collection and/or assembly of data, data analysis and interpretation, manuscript writing. RGT, DSS, JK, YR, TFH, DA, and CTR were responsible for the collection and/or assembly of data, data analysis and interpretation. BA and DM were responsible for collection and/or assembly of data. AME was responsible for statistical analyses review. MJH, JR, NLA, and MJB were responsible for conception and design. TKT was responsible for conception and design, financial support, collection and/or assembly of data, data analysis and interpretation, manuscript writing and final approval of manuscript. EMR was responsible for writing and editing the manuscript.
Authors’ information: TKT has clinical training and national certifications in Rheumatology, Allergy, and Immunology and has a translational/basic science background in immunology and autoimmunity. For the last 14 years, the TKT lab has studied chemokine receptor regulation by intracellular kinases and regulators of G protein signaling, with particular focus on their effects in immune cell regulation, metastasis, human translational studies of rheumatoid arthritis, and in animal models of bone and arthritis disease.

Acknowledgements: we would like to acknowledge our use of The UNC Flow Cytometry Core Facility (supported in part by P30 CA016086 Cancer Center Core Support Grant to the UNC Lineberger Comprehensive Cancer Center), The UNC Hooker Imaging Core, and the ENCODE Consortium using Dr. Thomas Gingeras’ (Cold Spring Harbor Labs) RNA-seq database of human BmMSCs. We would like to thank Dr. Bryan Roth (UNC) for the TANGO constructs and Dr. Robert Lefkowitz (Duke) for the Grk3-/- mouse strain.

Additional Files

Supplemental Materials and Methods.

**BmMSC cell surface markers.** BmMSCs were analyzed for cell surface markers by flow cytometry using the commercially available mouse mesenchymal stem cell marker antibody panel (R&D Systems, SC018) and performed as per instructions.

**shRNA GRK3-knockdown of BmMSCs.** Wildtype (WT) BmMSCs were cultured in 6-well plates, transfected at 50% confluency in media containing 8 µg/mL polybrene with lentiviral particles (Sigma NonTarget #1 pLKO 1-neo or GRK3 TRCN0000022702 pLKO 1-neo), and incubated at 37ºC for 40 hours with one media change at 20 hrs. BmMSCs were then cultured in media containing 1 µg/mL puromycin for selection. GRK3 knockdown efficiency by qRT-PCR was 87% of relative expression.

**CCK-8 Proliferation with CXCL12 and AMD3100.** 5x10^4 BmMSCs/well were cultured in a 6-well plate and treated with CXCL12 (Shenandoah, 200-46) or with CXCR4-antagonist AMD3100 (Sigma, A5602) at specified concentrations for six days.

**Capillary electrophoresis analysis of BmMSC lysates.** 8-9x10^5 BmMSCs were placed into a non-siliconized tube, and 10 µM sphingosine fluorescein (SF) (Echelon Biosciences Inc.) was added for 30 minutes at 37ºC. Cells were pelleted and resuspended in extracellular buffer (ECB; 135 mM NaCl, 5 mM KCl, 1 mM MgCl2, 1 mM CaCl2, and 10 mM N-2-hydroxyethylpiperazine-N’-2-ethanesulfonic acid (HEPES), pH 7.4, 37ºC). The cells were lysed by the addition of an equal volume of methanol. Lysate was diluted 1:40 with phosphate-propanol buffer (27 mM sodium phosphate and 10% 1-propanol at pH 7.3), and the sample was loaded into the capillary by hydrodynamic injections, and electrophoresed by applying a negative voltage to the outlet while the inlet was grounded. CE separations were performed at 450 V cm⁻¹ using the phosphate-propanol buffer. Fused-silica capillaries (Polymicro Technologies, Phoenix, AZ) with
an inner and outer diameter of 30 and 360 μm, respectively, were used for the electrophoresis. The total length of the capillary was 35 cm and the length from the inlet to the detection window was 4 cm. A custom-built epifluorescence detection system on a microscope stage was used to collect fluorescence data, as has been described previously (57). Peaks on the electropherograms were identified by comparing to known standards. Data were collected with a custom-built LabVIEW program and was analyzed with a custom made MatLab program to identify peaks. Each lysate sample was electrophoresed in triplicate.

**S1PR1 immunoblotting.** Cell lysis and SDS-PAGE was performed as detailed in the Materials and Methods, with the following changes: 50 µg of protein was freshly loaded onto AnyKD MiniPROTEAN® TGX precast protein gel (Bio-Rad, 4569034), the membrane was blocked in 5% milk in TBS/T for 2 hours at 25ºC, and incubated with primary antibody 1:500 S1PR1 (Santa Cruz, SC25489) or 1:10,000 GAPDH (Trevigen, 2275-PC-100) for 2 hours at 4ºC.

**Supplemental References.**

**Additional File 1: Supplemental Figure S1 (.TIF) Mouse mesenchymal stem cell marker panel.** WT (top) and Grk3-/-(bottom) BmMSCs expression of positive markers CD106, CD73, CD44, CD29, Sca1 and negative hematopoietic markers CD45 and CD11b (macrophage). Data plotted as percent (normalized to mode).

**Additional File 2. Supplemental Figure S2 (.TIF) GRK3-knockdown (GRK3-KD) BmMSCs have enhanced osteogenic differentiation in comparison to Non-target (NT) control BmMSCs.** shRNA Non-target (NT) control and GRK3-knockdown (GRK3-KD) BmMSCs have comparable adipogenic differentiation (Oil Red O stain); however, GRK3-KD BmMSCs show enhanced osteogenic differentiation (Alizarin Red stain), similar to BmMSCs isolated from Grk3-/- mice. Images captured at 10X magnification using the Olympus 1X-81 microscope and MetaMorph software.

**Additional File 3. Supplemental Figure S3 (.TIF) BmMSC proliferation was not affected by CXCL12 stimulation or CXCR4 signaling inhibition with AMD3100.** (A) Cellular proliferation was not enhanced in the presence of CXCL12, a CXCR4 agonist, at various concentrations, and (B) cellular proliferation was not reduced in the presence of AMD3100, a CXCR4 antagonist at various concentrations. Data represent mean ± SEM, n=3.

**Additional File 4. Supplemental Figure S4. (.TIF) WT and Grk3-/BmMSCs have comparable sphingosine kinase activity.** WT and Grk3-/BmMSCs were treated with fluorescein-labeled sphingosine to assess the BmMSC ability to convert sphingosine to active ligand sphingosine-1-phosphate (S1P) through sphingosine kinase (SphK) activity. WT and Grk3-/BmMSC converted sphingosine into S1P (i.e.: SphK activity) at comparable levels. Data represent mean ± SEM, n=3.
Additional File 5. Supplemental Figure S5 (.TIF) WT and *Grk3*-/BmMSCs express S1PR1. (A) Immunoblot detection of S1PR1 from both WT and *Grk3*-/BmMSC lysates, and (B) flow cytometry detection of surface S1PR1 (PE-conjugated) on Sca1+ (APC-conjugated) WT and *Grk3*-/BmMSCs.
