(Dated: May 16, 2018)

A novel integral representation for scattering phase shifts is obtained based on a modified version of Milne’s phase–amplitude approach [W. E. Milne, Phys. Rev. 35, 863 (1930)]. We replace Milne’s nonlinear differential equation for the amplitude function \(y\) with an equivalent linear equation for the envelope \(\rho = y^2\), which renders the integral representations highly amenable to numerical implementations. The phase shift is obtained directly from Milne’s phase function, which in turn is expressed in terms of the envelope function. The integral representation presented in this work is fully general and it can be used for any type of scattering potential, including the Coulomb potential.

I. INTRODUCTION

The phase–amplitude approach for Schrödinger’s radial (or one-dimensional) equation was pioneered by Milne [1], and has since been used extensively in atomic and molecular physics [2–14], in chemical physics [15–17], and in other areas of physics [18–28]. Although it was originally intended for tackling bound states, the phase–amplitude method is also applicable for scattering problems; indeed, Milne’s approach is especially suitable in the framework of many-channel quantum defect theory [29–32] because it makes it possible to construct optimal reference functions in each scattering channel.

The virtues of Milne’s approach stem from the fact that phases and amplitudes are quantities which are well behaved in the energy domain, even across channel thresholds. Moreover, the phase–amplitude method allows for highly efficient numerical implementations, because the direct computation of highly oscillatory wave functions can be avoided entirely; instead, any solution of the radial equation is evaluated accurately in terms of the amplitude and phase functions, which have a simple radial dependence.

In this work we use a modified version of Milne’s method to derive a novel integral representation which yields the true value of the scattering phase shift, despite the modulo \(\pi\) ambiguity inherent in its usual definition. We begin with a simple integral representation in Sec. II A which we generalize for the Coulomb case in Sec. II B. We give a brief discussion of envelope and phase functions in Sec. II C with additional details of the phase–amplitude approach presented in the Appendix. In Sec. II D we derive a two-envelope formula for phase shifts, which is essential for high partial waves. The computational approach is discussed in Sec. III, and we illustrate the practical usefulness of our integral representations with numerical applications in Sec. IV. Finally, we give concluding remarks in Sec. V.

II. THEORY

We consider the radial Schrödinger equation for a spherically symmetric potential \(V(R)\),

\[
\psi'' = U\psi, \quad U = 2\mu(V_{\text{eff}} - E),
\]

where \(V_{\text{eff}}(R) = V(R) + \frac{\ell(\ell+1)}{2\mu R^2}\) is the effective potential, \(\mu\) is the reduced mass of the two particles undergoing scattering, and \(E > 0\) is the energy in the center-of-mass frame. Atomic units are used throughout.

Assuming that the interaction potential \(V(R)\) vanishes faster than \(R^{-1}\) asymptotically, the physical solution \(\psi(R)\) has the well known asymptotic behavior

\[
\psi(R) \xrightarrow{R\to\infty} \sin(kR - \frac{\ell \pi}{2} + \delta_{\ell}),
\]

which yields the scattering phase shift \(\delta_{\ell}\) for partial wave \(\ell\). In the equation above, \(k = \sqrt{2\mu E}\) is the momentum for the relative motion. The phase shift is usually obtained from the matching condition,

\[
\psi(R) = Af(R) + Bg(R),
\]

where \(f\) and \(g\) are exact solutions of the radial equation, specified by their asymptotic behavior,

\[
f(R) \xrightarrow{R\to\infty} \sin(kR - \frac{\ell \pi}{2}) \quad \text{and} \quad g(R) \xrightarrow{R\to\infty} \cos(kR - \frac{\ell \pi}{2}).
\]

From the equations above we have \(\delta_{\ell} = \arctan(B/A)\), which yields the phase shift modulo \(\pi\), i.e., \(\delta_{\ell} \in \left[-\frac{\pi}{2}, \frac{\pi}{2}\right]\). To simplify our notation, we shall omit the label \(\ell\) for \(\psi, f, g\) and other related quantities, except for the phase shift \(\delta_{\ell}\).

A. Integral representation for the full phase shift

We now derive an expression for \(\delta_{\ell}\) which does not rely on the explicit evaluation of wave functions; instead, the phase shift will be extracted from an \(R\)-dependent phase function. Our approach follows Milne’s phase–amplitude method [1], which we review in appendices A, B, C. We emphasize that the true value of \(\delta_{\ell}\) will be obtained, despite the modulo \(\pi\) ambiguity inherent in its customary definition.

We first introduce the envelope function

\[
\rho = f^2 + g^2,
\]

with \(f\) and \(g\) exact solutions of the radial equation [1] obeying the asymptotic behavior (4, 5). The phase function \(\theta\) is constructed by integrating

\[
\theta' = \frac{d\theta}{dR} = \frac{k}{\rho},
\]
We remark that $\theta(R)$ is defined up to an integration constant, which can be chosen freely; a judicious choice guided by the computational strategy shall be made in Sec. II C.

As shown by Milne [1], the general solution of the radial equation [1] can be represented exactly in terms of $\rho$ and $\theta$. In particular, the physical solution reads

$$\psi(R) = \sqrt{\frac{\rho(R)}{R}} \sin[\theta(R) - \theta(0)].$$  \hspace{1cm} (8)

Note that $\psi(R)$ vanishes explicitly at $R = 0$, while Eqs. 4, 5 ensure a very simple asymptotic behavior for $\rho$ and $\theta$,

$$\rho(R) \xrightarrow{R \to \infty} 1$$ \hspace{1cm} (9)

$$\theta(R) \xrightarrow{R \to \infty} kR + \text{const}.$$ \hspace{1cm} (10)

We now define the reduced phase

$$\tilde{\theta}(R) \equiv \theta(R) - kR,$$ \hspace{1cm} (11)

and use Eqs. 9, 10 to find the asymptotic behavior of Milne’s parametrization [8],

$$\psi(R) \xrightarrow{R \to \infty} \sin[kR + \tilde{\theta}(\infty) - \theta(0)],$$

which is identical to the asymptotic behavior of $\psi$ in Eq. 2. Consequently, we obtain

$$\delta_\ell - \ell \frac{\pi}{2} \equiv \tilde{\theta}(\infty) - \theta(0).$$ \hspace{1cm} (12)

Making use of Eq. 11 we have $\theta(0) = \tilde{\theta}(0)$, and Eqs. 7, 11 yield $\tilde{\theta}' = \frac{k}{\rho} - k$. Hence, Eq. 12 can be recast as an integral representation,

$$\delta_\ell - \ell \frac{\pi}{2} = \tilde{\theta}(\infty) - \tilde{\theta}(0)$$

$$= k \int_0^\infty \frac{dr}{\rho(r)} - 1.$$ \hspace{1cm} (13)

We remark that the reduced phase $\tilde{\theta}(R)$ defined in Eq. 11 cannot be regarded as the nontrivial phase contribution, as it also includes the Bessel contribution (due to the centrifugal term). Therefore, strictly speaking, the equation above yields the full phase shift ($\delta_\ell - \ell \frac{\pi}{2}$).

### B. Generalization to potentials with a Coulomb term

So far, we assumed that the potential $V(R)$ vanishes faster than $R^{-1}$ asymptotically. In this section we consider the general case when $V(R)$ contains a Coulomb term,

$$V_C(R) = \frac{Z_1Z_2}{R},$$ \hspace{1cm} (14)

with $Z_{1,2}$ the electric charges of the two colliding particles. The remainder $(V - V_C)$ of the interaction potential is responsible for the phase shift $\delta_\ell$, which is obtained from the well known asymptotic behavior

$$\psi(R) \xrightarrow{R \to \infty} \sin[kR - \frac{C}{k} \ln(2kR) + \eta_\ell - \ell \frac{\pi}{2} + \delta_\ell],$$ \hspace{1cm} (15)

where $\eta_\ell = \arg\Gamma(\ell + 1 + i\frac{\pi}{2})$ is the Coulomb phase shift [33], and $C = \mu Z_1Z_2$. Following the same steps as in the previous section, we use again Milne’s parametrization [8] for the physical wave function, namely $\psi(R) = \sqrt{\rho(R)} \sin[\theta(R) - \theta(0)]$, with the phase $\theta$ behaving asymptotically as

$$\theta(R) \xrightarrow{R \to \infty} kR - \frac{C}{k} \ln(2kR) + \text{const},$$ \hspace{1cm} (16)

which is the generalized version of Eq. 10. Accordingly, the reduced phase is again defined such that it is finite asymptotically,

$$\tilde{\theta}(R) \equiv \theta(R) - kR + \frac{C}{k} \ln(2kR),$$ \hspace{1cm} (17)

and thus the full phase shift reads

$$\delta_\ell - \ell \frac{\pi}{2} + \eta_\ell = \tilde{\theta}(\infty) - \theta(0),$$ \hspace{1cm} (18)

which is the general form of Eq. 12.

In the Coulomb case, an integral representation can only be written if we divide the radial domain in two intervals. Indeed, unlike the previous section, $\tilde{\theta}$ now diverges logarithmically when $R \to 0$. Thus, we shall employ $\theta(R)$ for $R \leq R_0$ and $\tilde{\theta}(R)$ for $R \geq R_0$, with $R_0$ fixed arbitrarily. Specifically, we have

$$\theta(R_0) - \theta(0) = k \int_0^{R_0} \frac{dr}{\rho(r)}$$

$$\tilde{\theta}(\infty) - \tilde{\theta}(R_0) = k \int_{R_0}^\infty \left[ \frac{1}{\rho(r)} - 1 + \frac{C}{k r^2} \right].$$

Adding the two equations above, and making use of Eq. 17 at $R = R_0$, we find

$$\delta_\ell - \ell \frac{\pi}{2} + \eta_\ell = \tilde{\theta}(\infty) - \theta(0)$$

$$= k \int_0^{R_0} \left[ \frac{1}{\rho(r)} - 1 \right] + \frac{C}{k} \ln(2kR_0)$$

$$+ k \int_{R_0}^\infty \frac{dr}{\rho(r)} \left[ \frac{1}{\rho(r)} - 1 + \frac{C}{k r^2} \right],$$ \hspace{1cm} (19)

which represents the generalization of Eq. 13. Indeed, in the absence of the Coulomb term, i.e., setting $C = 0$ in the equations above, we have $\eta_\ell = 0$, and we recover the results of Sec. II A. We emphasize that the expression in Eq. 19 is independent of $R_0$, which we illustrate with numerical results in Sec. IV A. Finally, we remark that Eqs. 13, 19 yield the true value of $\delta_\ell$ unambiguously (not modulo $\pi$), and in the case of a purely Coulombic potential, Eq. 19 yields the true value of $\eta_\ell$.

### C. Envelope and phase functions

In order to use the approach outlined above in numerical applications, it is necessary to devise a reliable method for computing the envelope directly, rather than using Eq. 6. As shown in App. 15, $\rho$ obeys a linear differential equation,

$$\rho'' - 4U \rho' - 2U' \rho = 0.$$ \hspace{1cm} (20)
Therefore, we now regard the envelope \( \rho = f^2 + g^2 \) in Eq. (6) as a particular solution of Eq. (20). Namely, we impose the asymptotic boundary condition \( \rho(R) \to 1 \), which makes the solution unique. As we shall see in Sec. III, we initialize the envelope at \( R = \infty \) and we propagate it inward; accordingly, we also propagate the reduced phase \( \tilde{\theta} \) inward from \( R = \infty \).

Recall that Eq. (7) allows for an integration constant to be chosen freely when constructing the phase \( \bar{\theta}(R) \) or \( \hat{\theta}(R) \). The integration constant can be fixed, e.g., by setting the value of \( \theta(0) \), or the value of \( \tilde{\theta}(\infty) \). We prefer the latter, which is suitable when employing the inward propagation mentioned above; specifically, we choose

\[
\tilde{\theta}(\infty) = 0,
\]

and thus Eq. (12) reads

\[
\delta_i = \ell \frac{\pi}{2} - \theta(0). \tag{21}
\]

The reduced phase is constructed by direct integration; in the absence of a Coulomb interaction term, we have

\[
\tilde{\theta}(R) = k \int_R^{\infty} dr \frac{\tilde{\rho}(r)}{\rho(r)}, \tag{22}
\]

where \( \tilde{\rho} \) denotes the reduced envelope

\[
\tilde{\rho} \equiv \rho - 1.
\]

In the Coulomb case we make use of \( \tilde{\theta}'(r) = \frac{k}{\rho(r)} - k + \frac{C}{k} \), see Eqs. (7, 17), and thus the reduced phase reads

\[
\tilde{\theta}(R) = k \int_R^{\infty} dr \left[ 1 - \frac{1}{\rho(r)} - \frac{C}{k^2} \right]. \tag{23}
\]

In order to show that the integral above is well defined and yields a reduced phase obeying \( \tilde{\theta}(\infty) = 0 \), and also to justify that the full phase \( \theta(R) \) has the asymptotic behavior (16), we write the envelope as an asymptotic series,

\[
\rho(R) = 1 + \sum_{n=1} b_n R^n. \tag{24}
\]

Assuming the potential has the long-range behavior

\[
V(R) = \sum_{n=1} C_n \frac{1}{R^n}, \quad \text{with} \quad C_1 = C = \mu Z_1 Z_2,
\]

we substitute the ansatz (24) in Eq. (20), and we obtain the coefficients \( b_n \). In particular, for \( n = 1 \) we have \( b_1 = C/k^2 \), and thus the asymptotic behavior of the envelope reads

\[
\rho(R) \approx 1 + \frac{C}{k^2 R} + \frac{b_2}{R^2} + \ldots.
\]

Substituting the result above in Eq. (7) yields \( \theta' \approx k - \frac{C}{k R} + \tilde{\theta}'(\frac{1}{R^2}) \), which upon integration confirms Eq. (16), while the reduced phase in Eq. (23) has the asymptotic behavior

\[
\tilde{\theta}(R) \approx \frac{b_1}{R} + \frac{b_2}{R^2} + \cdots R \to \infty \to 0,
\]

where the coefficients \( b_n \) are expressed in terms of \( b_n \), e.g., \( b_1 = b_2 - b_1^2 \).

For computational purposes, it is advantageous to employ the reduced envelope

\[
\tilde{\rho} = \rho - 1 - \frac{C}{k^2 R}. \tag{25}
\]

Thus, we recast Eq. (23) in terms of \( \tilde{\rho} \),

\[
\tilde{\theta}(R) = k \int_R^{\infty} dr \frac{1}{\rho(r)} \left[ \left( 1 - \frac{C}{k R} \right) \tilde{\rho}(r) - \left( \frac{C}{k^2 R} \right)^2 \right]. \tag{26}
\]

The full phase shift in Eq. (19) can now be expressed in a form suitable for computation,

\[
\delta_i - k \frac{\pi}{2} + \eta_\ell = -\theta(0) \approx k \int_0^{R_0} dr \left[ \frac{1}{\rho_\ell(r)} - k R_0 + \frac{C}{k} \ln(2k R_0) - \tilde{\theta}(R_0) \right]. \tag{27}
\]

We emphasize that \( \tilde{\theta} \) should be computed using Eq. (26), because the integrand in Eq. (23) suffers from cancellation at large \( r \). Thus, in the asymptotic region, \( \tilde{\rho} \) should be obtained directly, rather than \( \rho \) itself; namely, we substitute \( \rho = \tilde{\rho} + 1 + C/k^2 R \) in Eq. (20) which becomes an equation for \( \tilde{\rho} \). The numerical approach for solving the envelope equation is described in Sec. III where we show that the entire asymptotic region can be treated in a numerically exact fashion by mapping it onto a finite interval and using a spectral Chebyshev method.

### D. Two-envelope formula for phase shifts

We now derive an integral representation which makes it possible to compute the phase shift \( \delta_i \) directly. Recall that the simple integral representations (13) and (19) yield the full phase shift (including Bessel and Coulomb contributions). As shown in Sec. IV, accurate values of \( \delta_i \) at high \( \ell \) cannot be obtained using Eq. (13). Thus, in this section we formulate a two-envelope approach which can be used to compute accurate phase shifts for all partial waves. For the sake of generality, we consider two different potentials \( V_1 \) and \( V_2 \), each containing the same Coulomb interaction term (if present). For a given scattering energy, \( E > 0 \), and a partial wave \( \ell \), we make use of Eq. (18) for each potential, and we employ the convenient choice \( \theta_1(\infty) = \theta_2(\infty) \) to find

\[
\delta_i^{(2)} - \delta_i^{(1)} = \theta_1(0) - \theta_2(0), \tag{28}
\]

Using \( \theta_{1,2}(r) \), see Eq. (7), the phase difference above can be recast as an integral,

\[
\delta_i^{(2)} - \delta_i^{(1)} = k \int_0^{\infty} dr \left[ \frac{1}{\rho_2(r)} - \frac{1}{\rho_1(r)} \right]. \tag{29}
\]

Although both \( \theta_{1,2}(r) \) diverge when \( R \to \infty \), the integral above is finite because the phase difference \( \theta_1(R) - \theta_2(R) = \theta_1(R) - \bar{\theta}_1(R) \) vanishes asymptotically. Note that in the asymptotic region we have \( \rho_1 \approx \rho_2 \), which can also hold in the
inner region if \( V_1 \approx V_2 \). Thus, Eq. (29) will suffer from catastrophic cancellation, rendering it unsuitable for numerical applications. Nevertheless, we show next that a computationally robust integral representation based on the two-envelope approach can be formulated.

We choose \( V_1 = V_{\text{ref}} \) as a reference potential (with the corresponding effective potential including both the centrifugal and Coulomb terms, see below), while \( V_2 = V = V_{\text{ref}} + \tilde{V} \) is the full interaction potential. The reduced envelope and phase are now defined relative to the corresponding reference quantities,

\[
\begin{align*}
\hat{\rho} &= \rho - \rho_{\text{ref}}, \\
\hat{\theta} &= \theta - \theta_{\text{ref}}.
\end{align*}
\]

We employ a nontrivial reference problem by setting

\[
U_{\text{ref}}(R) = -k^2 + \frac{\ell(\ell + 1)}{R^2} + \frac{2C}{R}, \quad C = \mu Z_1 Z_2,
\]

and use Eqs. (28)–(29) with \( U_1 = U_{\text{ref}} \) given above and \( U_2 = U = U_{\text{ref}} + 2\mu \tilde{V} \). Thus, the Bessel phase shift \((-\ell \frac{\pi}{2})\) and the Coulomb phase shift \(\eta_\ell\) are both eliminated, and the phase shift \(\delta_\ell\) reads

\[
\begin{align*}
\delta_\ell &= -\hat{\theta}(0) \\
&= -k \int_0^\infty dr \frac{\hat{\rho}(r)}{\hat{\rho}(r)\rho_{\text{ref}}(r)}.
\end{align*}
\]

The reference envelope is the solution of Eq. (20),

\[
\rho_{\text{eff}}''' - 4U_{\text{eff}}\rho_{\text{eff}}'' - 2U_{\text{eff}}'\rho_{\text{eff}} = 0,
\]

while the reduced envelope obeys a non-homogeneous differential equation,

\[
\hat{\rho}''' - 4U\hat{\rho}'' - 2U'\hat{\rho} = 4\hat{U}'\rho_{\text{ref}} + 2\hat{U}'\rho_{\text{ref}},
\]

which was obtained by combining Eqs. (20) and (33). In the equation above we used the notation \( U \equiv U - U_{\text{ref}} = 2\mu \tilde{V} \). Note that in the absence of a Coulomb term, we use \( U_{\text{ref}} = -k^2 + \frac{\ell(\ell + 1)}{R^2} \), with \( V_{\text{ref}} = 0 \) and \( \tilde{V} = V \), which is illustrated with numerical results in Sec. 4. Finally, we remark that in the absence of a Coulomb term one can also use the trivial choice \( U_{\text{ref}} = -k^2 \) with \( \theta_{\text{ref}} = k R \), which yields \( \hat{\theta} \) identical to \( \hat{\theta} \) in Eq. (11), thus recovering the integral representation of the full phase shift given in Sec. II A.

In practical applications, one first solves Eq. (33) for the reference envelope, which is subsequently used in Eq. (34). The latter is solved to obtain \( \hat{\rho} \), and thus the full envelope is obtained: \( \rho = \rho_{\text{ref}} + \hat{\rho} \). We remark that the numerical approach used for the homogenizing envelope equation, see Sec. III, can also be employed for the non-homogeneous differential equation (34). The two-envelope approach is fully general, but is especially useful when \( U = 2\mu \tilde{V} \) is small, such that \( |\hat{\rho}| \ll \rho \approx \rho_{\text{ref}}, \) and thus \( \hat{\theta} \) and \( \delta_\ell \) will also be small.

### III. COMPUTATIONAL APPROACH

The integral representations derived in this article are valid in general; however, they are useful in numerical applications only if the integrands are well behaved. Specifically, the envelope should behave in a non-oscillatory fashion, which in turn ensures the smoothness of the phase function. In practice, there is considerable difficulty in finding the smooth envelope \( \hat{\rho} \), because the general solution of the envelope equation has an oscillatory behavior, as mentioned in App. A. In this section, a novel computational strategy for obtaining the smooth envelope in the asymptotic region is presented. We emphasize that finding the unique, smooth solution is critically important for the efficiency and accuracy of numerical schemes using our integral representations, and for using the phase–amplitude method in general.

For clarity, we assume that \( V(R) \) vanishes faster than \( R^{-1} \) asymptotically. As discussed in Sec. II A (see also App. C), we employ the initial condition \( \rho = 1 \) at \( R = \infty \) when solving Eq. (20). However, rather than using the radial variable, it is highly advantageous to reformulate the envelope equation by mapping the asymptotic radial domain onto a finite interval. We developed a convenient and efficient numerical implementation based on a simple change of variable,

\[
x = \frac{1}{R},
\]

which allows to take fully into account the long-range tail of any potential. Thus, the infinite radial interval \( R_1 < R < \infty \) is now mapped on a compact interval, \( x_1 > x > 0 \), with \( x_1 = \frac{1}{R_1} \). The boundary \( R_1 \), i.e., the size of the interval \([0, x_1]\), will be chosen to ensure the desired level of accuracy.

We now regard the envelope as an \( x \)-dependent function, and we present the computational approach for finding the smooth solution of the envelope equation inside the interval \([0, x_1]\). First, we rewrite Eq. (20) using \( x = \frac{1}{R} \) as the independent variable,

\[
x^4 \dddot{x} + 6x^3 \dddot{x} + 6x^2 \dddot{x} + 4U \dddot{x} - 2U' \dddot{x} = 0,
\]

where dots above symbols denote derivatives with respect to \( x \), e.g., \( \rho = d\rho / dx \). Recall that \( U = 2\mu V_{\text{eff}} - k^2 \). Next, we define

\[
u = \dddot{x},
\]

and we regard it as the unknown function. Making use of the initial condition \( \rho = 1 \) at \( x = 0 \), we write

\[
\rho(x) = 1 + \int_0^x dt \, u(t),
\]

which we substitute in the last term of Eq. (35) to obtain

\[
\left( 4k^2 - 8\mu V_{\text{eff}} + x^4 D_x + 6x^3 D_x + 6x^2 - 4\mu V_{\text{eff}} S_x \right) u = 4\mu V_{\text{eff}}.
\]

The operators \( D_x \) and \( S_x \) read

\[
D_x u = \frac{du}{dx}, \quad S_x u = \int_0^x dt \, u(t).
\]

We solve Eq. (36) using a spectral Chebyshev method \(35\)–\(40\), i.e., we employ a small number of Chebyshev polynomials \(T_n(x)\) with \( n = 0, 1, 2, \ldots, N - 1 \), which are mapped onto
the interval \([0, x_1]\). We expand the unknown function \(u(x)\) in the Chebyshev basis, and the operators \(D_x\) and \(S_x\) are represented as finite \((N \times N)\) matrices \([37,38]\). Thus, Eq. (36) becomes a simple linear system,

\[
MA = B,
\]

where the column \(A\) contains the Chebyshev coefficients of our unknown function,

\[
u(x) = \sum_{n=0}^{N-1} A_n T_n(x),
\]

\(B\) contains the Chebyshev coefficients for the expansion

\[
4 \mu V_{\text{eff}}(x) = \sum_{n=0}^{N-1} B_n T_n(x),
\]

and \(M\) is the matrix of the operator in Eq. (36).

\[
M = 4 k^2 - 8 \mu V_{\text{eff}} + x^4 D_x^2 + 6 x^3 D_x + 6 x^2 - 4 \mu V_{\text{eff}} S_x.
\]

\(M\) is singular, but its matrix \((M)\) in the small Chebyshev basis is well conditioned and thus yields highly accurate solutions: \(A = M^{-1} B\). The smooth envelope is obtained as the unique solution, because all the other solutions oscillate infinitely fast near \(x = 0\) \((R \to \infty)\) and they are thus eliminated; indeed, highly oscillatory behavior cannot be accommodated by the small number of Chebyshev polynomials. We emphasize that the linearity of the envelope equation is crucially important for the feasibility of the approach presented here. Finally, the solution obtained inside the interval \([0, x_1]\) can now be used to initialize the propagation for \(x > x_1\), i.e., \(R < R_1\). A detailed description of our computational approach will be published elsewhere.

The advantage of the phase–amplitude method combined with the change of variable \(x = 1/R\) is readily apparent in Fig. 1 where we show the \(x\)-dependence of the reduced phase \(\hat{\theta}(x)\) and the envelope \(\rho(x)\) along with \(|\psi|^2\) for \(\ell = 475\) and \(E = 0.002\) a.u., for the potential energy used in Sec. IV.B see Eq. (39). Note that the wave function in Fig. 1 was evaluated numerically using Eq. (38), i.e., \(\psi = \sqrt{\tau} \sin(\theta - \theta_{R=0})\).

When the potential has a repulsive wall at short range, the formulation of the phase–amplitude approach based on the change of variable \(x = 1/R\) can be employed for the entire radial domain, as shown in Fig. 1. Indeed, the repulsive wall makes it possible to stop the inward propagation at \(R_{\text{min}} > 0\), which corresponds to a finite value \(x_{\text{max}} = 1/R_{\text{min}}\). We remark that, when the inward propagation of the reduced phase \(\hat{\theta}\) approaches the repulsive wall, it is convenient to convert it to the full phase \(\theta\) using Eq. (11) at a point \(R_0\) just outside the inner wall; for the remainder of the radial domain \((R < R_0)\), one should propagate \(\theta(R)\) instead of \(\hat{\theta}(R)\), because the former converges much faster than the latter. Indeed, if \(V_{\text{eff}} \to +\infty\) when \(R \to 0\), we have \(\rho \to \infty\) and \(\theta' \to 0\), while \(\hat{\theta}' \to -k\). In other words, \(\theta(0)\) should be computed as

\[
\theta(0) = k R_0 + \int_{R_0}^{\infty} dr \frac{\hat{\theta}(r)}{\rho(r)} - k \int_{R_{\text{min}}}^{R_0} dr \frac{\rho}{\rho(r)}.
\]

Fig. 1. Upper: effective potential \((\ell = 475)\) as a function of \(x = 1/R\). \(V(R)\) is given in Eq. (39). The values of \(R\) are indicated at the top. The horizontal dashed line marks the energy \(E\). Middle: thin line (gray) for the wave function, thick line (red) for the envelope. Lower: reduced phase \(\tilde{\theta}(x)\).

IV. EXAMPLES

We now apply the integral representations and show that they yield highly accurate results. Our first example is the Coulomb potential, which we use as a test case for the integral representation (27). The two-envelope formula, see Eqs. (28) and (32), will be employed and tested in Sec. IV.B.
A. The Coulomb potential

In the case of a purely Coulombic potential, Eq. (27) yields the Coulomb phase shift,

\[ \eta_{\ell} = \frac{\ell}{2}kR_0 + \frac{k}{2}\ell \ln(2kR_0) + k\int_0^{R_0} \frac{d\rho}{\rho^\ell} - \tilde{\theta}(R_0), \]  

(38)

with \( \tilde{\theta} \) given Eq. (26). The result above is independent of \( R_0 \), as depicted in Fig. 2. Indeed, we show that our approach is robust and accurate by comparing the value of \( \eta_{\ell} \) obtained using Eq. (38) with the exact value \( \eta_{\ell}^f = \arg\Gamma(\ell + 1 + \ell C) \) for \( C = -1 \), \( k = 0.1 \) and \( \ell = 5 \). Our integral representation yields the value \( \eta_{\ell} = -20.22421961527 \), while the analytical expression gives its value modulo \( 2\pi \), namely \( \eta_{\ell}^f = -1.3746636937335435 \). Their difference equals an integer multiple of \( 2\pi \) to a high degree of precision: \( (\eta_{\ell} - \eta_{\ell}^f)/2\pi = -3(1 \pm 10^{-13}) \). Figure 2 depicts the relative error \( |(\eta_{\ell} - \eta_{\ell}^f + 6\pi)/\eta_{\ell}| \) as a function of \( R_0 \).

B. Results for an inter-atomic potential with long-range behavior of the type \( V(R) \sim -\frac{C_3}{R^5} \)

For our second example we use both integral representations, i.e., Eq. (13) for the full phase shift and the two-envelope formula (32) which yields the phase shift directly. We employ the potential energy

\[ V(R) = C_{\text{wall}} \exp \left( -\frac{R}{R_{\text{wall}}} \right) - \frac{C_3}{R^5 + R_{\text{core}}^5}, \]  

(39)

with \( C_{\text{wall}} = 10, R_{\text{wall}} = 1, R_{\text{core}} = 5 \) and \( C_3 = 18 \) (all in atomic units), and the reduced mass \( \mu = \frac{m}{2} \), where \( m \) is the mass of \( ^{88}\text{Sr} \). We computed phase shifts for \( E = 0.01 \) a.u. \( \approx 0.272 \) eV for a wide range of partial waves. The upper panel in Fig. 3 depicts the \( \ell \) dependence of the phase shift, while the lower panel shows the partial-wave terms of the elastic cross section, \( \sigma_{\ell} = \frac{4\pi}{k^2} (2\ell + 1) \sin^2 \delta_{\ell} \). An exceedingly large number of partial waves contribute to the cross section; note that the dominant contribution stems from very high partial waves \( (\ell > 5000) \). For a fully converged value of the elastic cross section, we have computed phase shifts up to \( \ell = 10^5 \).

Recall that our integral representations yield the true value of the phase shift (not modulo \( \pi \)) which has a rather simple \( \ell \)-dependence; this suggests that interpolation schemes could be used to drastically reduce the number of partial waves for which phase shifts need to be computed. This added advantage is illustrated in Fig. 4 where we compare the true phase shift with its modulo \( \pi \) version. Moreover, our approach is not restricted to integer values of \( \ell \), and makes it possible to use non-integer values of \( \ell \) as interpolation points; thus, highly accurate interpolation methods with non-uniform grids, e.g., Chebyshev interpolation, can be employed.

Regarding the practical aspects of the computation, some remarks are in order. We first emphasize that, using the computational approach presented in Sec. III the simple integral representation (13) and the two-envelope formula (32) can be implemented numerically such that they both yield accurate results. However, when using the integral representation (13) for the full phase shift, the value of \( \delta_{\ell} \) obtained from Eq. (21) will gradually lose precision at very high \( \ell \). Indeed, for \( \ell \to \infty \) we have \( \delta_{\ell} \to 0 \) while \( \theta(0) \approx \ell \frac{\pi}{2} \). Therefore, the simple integral representation (13) must be avoided at high \( \ell \) because of the catastrophic cancellation in Eq. (21), even though \( \theta(0) \) can still be computed accurately. Consequently, when \( \ell \) becomes extremely large, \( \delta_{\ell} \) should instead be computed using the two-envelope formula derived in Sec. II D.

Although the two-envelope formula is highly accurate for all partial waves, Eq. (13) has the advantage of much greater simplicity and could be used at low \( \ell \), provided that it is suf-
ingly accurate. A simple rule of thumb exists for finding the highest partial wave for which Eqs. (13, 21) yield accurate results. Namely, the two-envelope formula needs to replace the simple formula only if \( \ell \) is high enough for the centrifugal term to become dominant over \( V(R) \). However, at low \( \ell \) the simple formula is highly accurate, as we show next.

First, we performed a test for the Bessel case, \( V_{\text{eff}} = \frac{\ell(\ell+1)}{2\mu R^2} \), with \( V = 0 \), in order to show that the two-envelope formula is robust and accurate even for very high \( \ell \). Namely, we computed directly the vanishingly small difference between the Bessel phase shifts for \( \ell_1 \) and \( \ell_2 \) which are nearly equal. We used \( \ell_1 = \ell \) and \( \ell_2 = \ell - \frac{1}{2} \), for which the exact value of \( \delta_\ell = \delta_B(\ell_2) - \delta_B(\ell_1) \) is \( \delta_\ell = \frac{\pi}{2} \), where \( \delta_B(\ell) = -\ell \frac{\pi}{2} \) denotes the Bessel phase shift. The relative error of the numerical value \( \delta_\ell \) obtained with the two-envelope formula is shown in Fig. 5 confirming that high accuracy is preserved at high \( \ell \), despite the smallness of \( \delta_\ell \). In contrast, if the exact values of \( \delta_B(\ell_{1,2}) \) are subtracted numerically, the loss of accuracy is significant and becomes catastrophic at very high \( \ell \), see Fig. 5. This also illustrates that the failure of Eq. (21) at high \( \ell \) cannot be avoided, as it is due to the cancellation of nearly equal quantities. Nevertheless, Eq. (21) is sufficiently accurate at low \( \ell \). Indeed, we performed a test for the simple integral representation (13). Assuming the two-envelope formula is numerically exact, the relative error for \( \delta_\ell \) computed using Eqs. (13, 21) for the nontrivial potential energy (39) is shown in Fig. 6 which makes it readily apparent that the simple formula is highly accurate for partial waves \( \ell \lesssim 600 \), while significant loss of precision only occurs for much higher partial waves.

V. CONCLUSIONS AND FUTURE WORK

In this work we presented a novel integral representation for scattering phase shifts. A simple version, Eq. (13), yields the so called full phase shift, while the two-envelope formula can be used to obtain \( \delta_\ell \) directly. We emphasize that, unlike standard approaches which only yield \( \delta_\ell \mod \pi \), our integral representations give the true value of the phase shift. The integral representations are very useful in numerical applications, as shown in Sec. IV; indeed, they can be easily implemented to obtain highly accurate results. Moreover, our approach is based on the phase–amplitude method, which avoids the explicit computation of highly oscillatory wave functions; thus, our numerical implementations are very efficient, and are consistently accurate even for very high partial waves.

We remark that our integral representations are always valid, but the computational advantages mentioned above rely on the assumption that the envelope is globally smooth. However, a globally smooth solution of the envelope equation (20).
does not always exist; indeed, as is well known \[15\], when a barrier separates two classically allowed regions, the solution which is smooth on one side of the barrier will oscillate on the other side. To overcome this computational difficulty, it is necessary to develop an optimization procedure for finding the locally smooth envelopes. In addition, one needs to find a way to combine the different solutions which are locally optimized in each classically allowed region. This is a nontrivial task, as it requires certain functional relationships be established between the envelopes and phases corresponding to disjoint regions which are separated by a barrier. If such an approach could be rendered computationally feasible, it would yield the true phase-shift even in the absence of a globally smooth envelope.

**Appendix A: The phase–amplitude approach**

A brief overview of Milne’s phase–amplitude approach is presented here. According to Milne \[1\], the general solution \(\psi\) of the radial equation (1) can be expressed in terms of an amplitude \(y\) and a phase \(\theta\),

\[
\psi(R) = cy(R)\sin[\theta(R) + \theta_0], \quad (A1)
\]

where \(c\) and \(\theta_0\) are arbitrary constants. The amplitude satisfies the nonlinear equation

\[
y'' = Uy + \frac{q^2}{y^3}, \quad (A2)
\]

with \(U = 2\mu(V_{\text{eff}} - E)\), and the phase \(\theta(R)\) is constructed by integrating

\[
\theta' = \frac{q}{y^2}. \quad (A3)
\]

In the equations above, \(q\) is arbitrary; the only restriction is \(q^2 > 0\) in the amplitude equation (A2). We emphasize that the amplitude and phase appearing in Milne’s parametrization (A1) are not unique; indeed, any solution \(y\) of Eq. (A2) together with the associated phase \(\theta\) will give a valid representation of \(\psi\). This undermines the advantage of Milne’s method in numerical applications, because the general solution \(y(R)\) of Milne’s nonlinear equation has an oscillatory behavior in classically allowed regions, and the unique smooth amplitude is very difficult to find \[4\]-[13]. Despite this difficulty, Milne’s nonlinear equation (A2) has long been used for computational work. We remark that an equivalent formulation based on a linear equation exists \[42\]-[43], but it remained overlooked in the physics community until recently \[44\]. As we show in App. [B] the linear equation can be obtained by simply replacing the amplitude with the envelope function \(\rho\),

\[
\rho(R) = y^2(R). \quad (A4)
\]

The envelope obeys a third order linear differential equation,

\[
\rho''' = 4U\rho' + 2U'\rho. \quad (A5)
\]

In App. [B] we present two different derivations for the envelope equation (A5), and in App. [C] we discuss its equivalence with Milne’s nonlinear equation (A2).

Although Eq. (A5) is of third order, its linearity makes it much more convenient than Milne’s nonlinear equation (A2). However, finding the non-oscillatory solution is still a difficult task. To overcome this obstacle, we devised a computational strategy for scattering problems \((E > 0)\) which yields the smooth envelope in the asymptotic region, see Sec. III.

**Appendix B: The envelope equation**

We present here two different derivations of the envelope equation (A5). The first derivation is very brief; namely, we substitute \(y = \sqrt{\rho}\) in equation (A2) and we find

\[
\rho'' = 2U\rho + \frac{1}{\rho} \left[ \frac{1}{2}(\rho')^2 + 2q^2 \right].
\]

Next, we multiply both sides by \(\rho\) to obtain

\[
\rho\rho''' = 2U\rho^2 + \frac{1}{2}(\rho')^2 + 2q^2, \quad (B1)
\]

which is still a nonlinear equation. However, now we take the derivatives of both sides,

\[
\rho\rho''' + \rho''\rho' = 4U\rho\rho' + 2U'\rho^2,
\]

and we divide by \(\rho\) to finally obtain Eq. (A5).

The second approach is similar to Milne’s derivation [11] of Eq. (A2). Namely, we consider two solutions (\(\phi\) and \(\chi\)) of the radial Schrödinger equation (1), and we try to find a differential equation for their product

\[
\rho \equiv \phi \chi.
\]

Making use of Eq. (1) for \(\phi\) and \(\chi\), we obtain

\[
\rho'' = 2U\rho + 2\phi'\chi',
\]

and we now evaluate its derivative,

\[
\rho''' = 2U'\rho + 2U\rho' + 2U(\phi'\chi' + \phi\chi'),
\]

where we recognize \(\rho' = \phi'\chi' + \phi\chi\), and we find again the envelope equation (A5),

\[
\rho''' = 4U\rho' + 2U'\rho.
\]

As the product of any two solutions of the radial equation obeys the envelope equation, \(\phi^2\) and \(\chi^2\) are also valid solutions of Eq. (A5), as well as any linear combination of \(\phi^2\), \(\chi^2\) and \(\phi\chi\) \[7\]-[13]. In particular, \(\rho = \phi^2 + \chi^2\) is a valid solution, which corresponds to Milne’s ansatz \(y = \sqrt{\phi^2 + \chi^2}\).
Appendix C: Milne’s amplitude equation as a constraint for the envelope equation

The parameter \( q \) appears explicitly in Milne’s nonlinear equation \((A2)\). However, \( q \) is absent from the envelope equation \((A5)\), even though it is used when integrating Eq. \((7)\) to obtain the phase \( \theta \). This creates some ambiguity, which stems from the fact Eq. \((A2)\) is a second order differential equation, while the Eq. \((20)\) is of third order. We now try to dispel the ambiguity and show that the two equations are equivalent. We first remark that although \( q \) does not appear in Eq. \((20)\), it should be assumed implicitly; indeed, if we recast Eq. \((B1)\) in the form

\[
\frac{1}{2} \rho \rho'' - U \rho^2 - \frac{1}{4} (\rho')^2 = q^2, \quad (C1)
\]

the expression on the left hand side can be interpreted as an invariant of the envelope equation \((A5)\), and any solution \( \rho \) will also obey Eq. \((C1)\) with a particular value of \( q^2 \). Recall that the equation above is equivalent with Milne’s equation \((A2)\), which can thus be regarded as a constraint for the envelope equation. Indeed, as we discuss below, Eq. \((C1)\) should be used to enforce the correct initial conditions for \( \rho \), such that they correspond to a fixed value for \( q \).

To fully clarify the equivalence of Eqs. \((A2)\) and \((A5)\), let us compare the sets of initial conditions required in each case. When we initialize \( \rho \) at \( R = R_0 \), we consider given

\[
\rho(R_0), \quad \rho'(R_0), \quad \rho''(R_0),
\]

which can be used in the constraint equation \((C1)\) evaluated at \( R = R_0 \) to obtain the value of \( q \). Conversely, if \( q \) is considered given, we have

\[
\rho(R_0), \quad \rho'(R_0), \quad q = \text{fixed},
\]

which we commonly employ in practice. Equation \((C1)\) is now used to obtain \( \rho''(R_0) \), and thus initialize the solution of the envelope equation. Equivalently, for Milne’s amplitude equation we consider given

\[
y(R_0), \quad y'(R_0), \quad q = \text{fixed}.
\]

Moreover, the families of solutions for different values of \( q \) are all equivalent. Indeed, if \( v_1 \) is a solution of Eq. \((A2)\) for a given parameter \( q_1 \), then \( y_2 = (q_2/q_1)^{1/2} y_1 \) is a solution for \( q_2 \). Similarly, we have \( \rho_2/q_2 = \rho_1/q_1 \), and \( \theta'_2 = \theta'_1 \). Varying the parameter \( q \) is entirely redundant, as the phase \( \theta \) remains unchanged, therefore justifying the convenient choice \( q = k \) used throughout this article.

Finally, we make use of the constraint in Eq. \((C1)\) to show that the choice \( q = k \) is consistent with the initial condition \( \rho = 1 \) at \( R = \infty \), which gives a convenient normalization for the envelope. Indeed, when \( R \to \infty \), we have \( V_{\text{eff}}(R) \to 0 \) and thus \( U(R) \approx U(\infty) = -k^2 \) and \( U' \approx 0 \), while for the envelope we have

\[
\rho(R) \approx \rho(\infty), \quad \rho'(R) \approx 0, \quad \rho''(R) \approx 0.
\]

Substituting these asymptotic values in Eq. \((C1)\) we obtain

\[
-U(\infty) \rho^2(\infty) = q^2,
\]

and using \( U(\infty) = -k^2 \), we find the parameter \( q \).

\[
q = k \rho(\infty).
\]

Conversely, if one prefers to choose a certain value for \( q \), the equation above yields \( \rho(\infty) = q/k \). However, as shown above, the normalization constant \( \rho(\infty) \) is irrelevant; indeed, we have

\[
\theta'(R) = \frac{q}{\rho(R)} = k \frac{\rho(\infty)}{\rho(R)},
\]

which ensures

\[
\theta'(R) \approx k, \quad \text{when } R \to \infty,
\]

and thus the phase function suitable for scattering problems, as defined in Sec. \((IIA)\) has the desired behavior:

\[
\theta(R) \approx kR, \quad \text{when } R \to \infty.
