Abstract

Background: Presently, CD133 is one of the hottest markers to characterize cancer stem cells and KAI1/CD82 is reported as an important marker for the metastasis and prognosis of many cancers. The purpose of our study is to explore the relationship between cancer stem cells (CSCs) marked by CD133 and KAI1/CD82 expression and the clinicopathological characteristics of patients with laryngeal squamous cell carcinoma (LSCC).

Methods: Immunohistochemical analysis was used to detect the expression of CD133 and KAI1/CD82 in 83 archival surgical specimens of human LSCC and 83 cases of normal laryngeal tissues.

Results: In LSCC, positive rates of 49.4% and 41.0% were obtained for CD133 and KAI1/CD82, respectively. The expression of CD133 in LSCC tissues was significantly higher than that in normal tissues (P < 0.001), and the expression of CD133 was positively associated with pTNM stage (P = 0.005), pathological grade (P = 0.001), and lymph node metastasis (P < 0.001). The reduced expression of KAI1/CD82 was present in LSCC tissues. The positive rate of KAI1/CD82 expression was negatively correlated with pTNM stage (P = 0.014), pathological grade (P < 0.001), and lymph node metastasis (P = 0.007). A correlation analysis showed that there was a negative relationship between the expression of CD133 and KAI1/CD82 protein in LSCC tissues (P < 0.001). By Kaplan-Meier analysis, the expression of CD133 was negatively correlated with overall survival (OS) (log-rank = 40.949, P < 0.001) and disease-free survival (DFS) (log-rank = 39.307, P < 0.001) time of LSCC. The expression of KAI1/CD82 was positively correlated with OS (log-rank = 40.279, P < 0.001) and DFS (log-rank = 39.271, P < 0.001) time of LSCC. Cox regression analysis: the expression of CD133 and KAI1/CD82, and pTNM stages were independent prognostic factors of LSCC (P < 0.05).

Conclusions: Thus the detection of CD133 and KAI1/CD82 proteins may be used as a potential indicator of LSCC prognosis.

Background

In the United States, laryngeal carcinoma accounted for approximately 0.82% of new cancer diagnoses and 0.40% of all cancer deaths in 2012 [1]. The major pathological type of laryngeal cancers is squamous cell carcinoma, accounting for 99% of laryngeal malignant tumors. Although rapid progress has recently been made in treatment, the prognosis for patients with laryngeal squamous cell carcinoma (LSCC) remains unsatisfactory. A major problem in finding treatments is the frequent resistance to drugs which emerges. This is linked to the development and maintenance of a small population of tumor cells, termed cancer stem cells (CSCs). These cells have the properties of self-renewal, proliferation, and multilineage differentiation and are responsible for sustaining the tumor [2] and are also thought to initiate tumor metastasis and therapy-resistance [3,4]. A commonly investigated potential CSC marker is CD133 (also known as prominin-1), a 120 kDa five transmembrane domain cell surface glycoprotein, which was initially considered to be one marker of hematopoietic stem cells [5,6]. Now, CD133 may represent a putative cancer stem cell marker.
in many solid tumors, such as human colon cancer [7,8], breast cancer [9,10], gastric cancer [11,12], glioblastoma [13], lung cancer [14,15], liver cancer [16,17], pancreatic cancer [18], prostate cancer [19], and cholangiocarcinoma [20].

Cancer metastasis involves multiple steps with a high degree of complexity and requires the contribution of a variety of molecules. The KAI1/CD82 gene was originally identified as a suppressor of metastasis of tumor in prostate carcinoma [21]. Recent study has shown that KAI1/CD82 gene expression is under-regulated in most metastatic cancers [22]. It is a member of the tetraspan transmembrane superfamily (TM4SF) and is a gene located on human chromosome 11p11.2. KAI1/CD82 plays an important role in cell fusion, adhesion, migration, signaling, fertilization, differentiation, and invasion [22-26]. Decreased KAI1/CD82 expression has been observed to correlate with metastasis and poor prognosis in many human solid tumors, such as prostate cancer [27], lung cancer [28], breast cancer [29], colon cancer [30], gastric cancer [31], liver cancer [32], and kidney cancer [33].

To date, the correlation between CD133 and KAI1/CD82 expression in LSCC is unknown. Therefore, this study intends to investigate CD133 and KAI1/CD82 expression in the specimens of postoperative LSCC patients following primary laryngeal resection in order to determine the correlation between the expression of CD133 and KAI1/CD82 and clinicopathological characteristics acceptable.

**Methods**

**Patients and specimens**

Paraffin embedded sections of 83 LSCCs and 83 normal laryngeal tissues were obtained from the Department of Pathology, the First Hospital Affiliated to Bengbu Medical College from January to November 2003. We excluded patients who received preoperative chemotherapy or radiotherapy. Approval for this study was not required by the ethical committee because the experiments carried out did not relate to patient privacy, impairment or treatment. The age of the patients ranged from 43 to 84 years; the median age was 62.1 years. The patients consisted of 75 males and 8 females. There were 43 cases whose tumors were <2.0 cm in diameter and 40 cases whose tumors were ≥2.0 cm. Thirty were at grade I, 47 were at grade II, and 6 were at grade III, according to the grading system of the World Health Organization. Fifty-one were of supraglottic type, 29 were glottic type, and three were subglottic type. A total of 49 specimens had no lymph node metastasis, whereas 34 specimens showed lymph node metastasis. According to clinical staging of pTNM, 21 were stage I, 32 were stage II, 22 were stage III, and 8 were stage IV.

**Immunohistochemical analysis**

All samples were fixed in 10% buffered formalin and embedded in paraffin. Four-micrometer thick tissue sections were used for analysis. All sections were deparaffinized and dehydrated with graded alcohol. Then, the sections were washed for ten minutes in PBS at pH 7.2. The endogenous peroxidase activity was quenched by incubation in methanol containing 3% H2O2 for ten minutes at room temperature, then heated for 30 minutes at 95°C to repair the antigens and finally rinsed in PBS. After several washes in PBS, sections were blocked with goat serum for 20 minutes at room temperature, and then incubated with mouse monoclonal CD133 (Santa Cruz Biotechnology Inc., Santa Cruz, CA, USA) and KAI1/CD82 (Santa Cruz Biotechnology Inc., Santa Cruz, CA, USA) primary antibodies overnight at 4°C in a humidified chamber. The slides were treated with polymer enhancer (reagent A) for 20 minutes at room temperature. Washing in PBS, the slides were treated with goat anti-mouse antibody (reagent B) for 30 minutes at room temperature. After a complete wash in PBS, the slides were developed in freshly prepared diaminobenzidine (DAB) solution for eight minutes, and then counterstained with hematoxylin, dehydrated, air-dried, and mounted.

Serial sections of LSCC were run in parallel with the primary antibody replaced by PBS and rabbit IgG1 as blank and negative controls.

**Evaluation of score**

Slides were reviewed independently by two observers to evaluate the staining pattern of the protein under the light microscope. Ten visual fields were randomly selected from each slide. In scoring expression of CD133 and KAI1/CD82 proteins, both the extent and intensity of immunopositivity were considered. The intensity of the positive result was scored as follows: 0, negative; 1, weak; 2, moderate; 3, strong. The extent of positivity was scored according to the percentage of cells that stained positive: <10% is 1; 11 to 50% is 2; 51 to 75% is 3; >75% is 4. The final score was determined by multiplying the intensity of positivity and the extent of positivity scores, which yielded a range from 0 to 12. Expression of CD133 and KAI1/CD82 were considered positive when the scores were ≥3.

The positive expression of CD133 was found mainly on the membrane and cytoplasm of LSCC cells and normal laryngeal tissues. The positive expression of KAI1/CD82 was found mainly on the membrane and cytoplasm of LSCC cells and normal laryngeal tissues. They were presented as a brown granular material.

**Statistical analysis**

Fisher’s exact test, Pearson Chi-square test for trends in proportions, Spearman’s correlate analysis, and Kaplan-
Meier’s method with log-rank test or Cox regression method for univariate or multivariate OS analysis were used to assess the associations among the positive staining of CD133 or KAI1/CD82 and clinicopathological indices. SPSS 17.0 software for windows (Chicago, IL, USA) was used for this purpose. A value of $P < 0.05$ was considered statistically significant.

Results
The association between the expression of CD133 or KAI1/CD82 and clinicopathological factors
CD133 protein was expressed positively in 49.4% (41/83) of LSCC and 4.8% (4/83) of normal laryngeal tissues. There was a significant difference between the LSCC group and the normal laryngeal tissues ($P < 0.01$) (Figure 1A and B). There was a positive relationship between the expression of CD133 and histological grade, pTNM stage, and lymph node metastasis ($P < 0.05$). The positive expression of KAI1/CD82 was 41.0% (34/83) in the LSCC group and 96.4% (80/83) in normal laryngeal tissues. A significant difference was found between the LSCC group and the normal group ($P < 0.05$) (Figure 2A and B). There was a negative relationship between the expression of KAI1/CD82 protein and alcohol, histological grade, pTNM stage, and lymph node metastasis ($P < 0.05$). However, the expression of CD133 and KAI1/CD82 was not associated with gender, age, tumor localization, smoking, and tumor diameter ($P > 0.05$) (Table 1).

Prognosis and multivariate analysis
Follow-up data showed that the OS rate and DFS rate for CD133-positive patients were significantly poorer than that of CD133-negative patients ($P < 0.001, P < 0.001$, Figure 3). Also, there was a significantly increasing trend in the mean OS survival time and DFS time between the carcinomas with the expression of KAI1/CD82 and those without ($P < 0.001, P < 0.001$, Figure 4). In the 83 LSCC patients, a univariate analysis (Table 2) revealed that the DFS survival significantly correlated with expression of CD133 ($P < 0.001$) and KAI1/CD82 ($P < 0.001$), tumor location ($P = 0.033$), grade of tumor ($P = 0.002$), lymph node metastasis ($P = 0.004$), and pTNM stages ($P < 0.001$). A multivariate analysis revealed expression of CD133 and KAI1/CD82, lymph node metastasis, and pTNM stages were independent prognostic factors for DFS and OS ($P < 0.05$) (Tables 3 and 4).

Correlation of CD133 and KAI1/CD82 in LSCC
There was a negative correlation between CD133 expression and KAI1/CD82 expression in LSCC ($r = -0.578, P < 0.001$).

Discussion
Cancer stem cells (CSCs), also known as tumor initiating cells (TICs), are a subpopulation of tumor cells with the stem cell capacity for self-renewal. They give rise to the differentiated cells, and generate the heterogeneous lineages of cancer cells that comprise the bulk of the tumor [2,7,11,20,34-39]. CSCs may originate by malignant transformation of normal stem cells or arise from restricted progenitors of more differentiated cells [40]. The protein CD133 is one of the hot CSC markers in a variety of tumors [7-20]. In this study, we found that the positive expression of CD133 was 49.4% in LSCC patients. The study investigated the expression of CD133 protein in 83 LSCC specimens with follow-up data and the results indicated that CD133 protein expression level was positively correlative with grade of tumor ($P = 0.001$), lymph node metastasis ($P < 0.001$), and pTNM stage ($P = 0.005$). Furthermore, we also found the expression of CD133 was significantly associated with OS time ($P < 0.001$) and DFS time ($P < 0.001$), suggesting the expression of CD133 might be a potential prognostic factor in LSCC. Another result is that not only LSCC cell express CD133 but also normal laryngeal tissue (squamous epithelial cells). This indicated that CD133 might play an important role in tumorigenesis [8].

Figure 1 Expression of CD133 protein in laryngeal squamous cell carcinoma. (A) CD133 was expressed as positive in the membrane of cancer cells (CD133 × 400). (B) CD133 was expressed as positive in the membrane of cancer cells at the invasive cancer (CD133 × 400).
Figure 2 Expression of KAI1/CD82 protein in laryngeal squamous cell carcinoma. (A) KAI1/CD82 was expressed as positive in the membrane of cancer cells (KAI1/CD82 × 400). (B) KAI1/CD82 was expressed as positive in membrane and cytoplasm of cancer cells (KAI1/CD82 × 400).

Table 1 Correlation of CD133 and KAI1/CD82 expression to clinicopathological characteristics in laryngeal squamous cell carcinoma (LSCC)

| Variable               | CD133       | P-value | KAI1/CD82   | P-value |
|------------------------|-------------|---------|-------------|---------|
|                        | Negative    | Positive| Negative    | Positive|
| Gender                 |             | > 0.05  | > 0.05      |         |
| Male                   | 36          | 39      | 46          | 29      |

| Moderately-differentiated| 18       | 29      | 35          | 12      |
| Poorly-differentiated  | 1           | 5       | 5           | 1       |
| Lymph node metastasis  |             | < 0.001 | < 0.01      |         |
| No                     | 33          | 16      | 23          | 26      |
| Yes                    | 9           | 25      | 26          | 8       |
| pTNM stage             |             | < 0.05  | < 0.05      |         |
| I and II               | 33          | 20      | 26          | 27      |
| III and IV             | 9           | 21      | 23          | 7       |
The metastasis suppressor gene KAI1/CD82 might be a useful marker for the metastatic and prognostic potential in a series of human tumors. The precise mechanism for the regulation of KAI1/CD82 is unclear. But, in the progression of many tumors, the most common mechanism was down-regulation or loss-regulation rather than mutation [22,24]. Our study results showed that KAI1/CD82 was negatively associated with grade of tumors ($P < 0.001$), lymph node metastasis ($P = 0.007$), and pTNM stage ($P = 0.014$). From further research, we found that the KAI1/CD82-positive group correlated with longer survival time, a result which was in agreement with previous reports [32,41,42].

Our research also showed that CD133 expression was negatively correlated with KAI1/CD82 expression ($P < 0.001$). CSCs can manipulate stromal cells to their needs in distant organs and thus prime the foreign soil for their arrival by inducing a premetastatic niche [43]. This indicates that CSCs have high migratory potential and
Table 2 Results of univariate analyses of disease-free survival (DFS) and overall survival (OS) time

| Variable                  | n   | Mean DFS (months) | P-value | Mean OS (months) | P-value |

may be responsible for metastasis [44]. Down-regulation of KAI1/CD82 may further promote the metastatic ability of CSCs. Although the precise molecular mechanism involved in this process is unclear, our research has potential clinical benefits. CD133 and KAI1/CD82 expression, which could be detected by immunohistochemistry, might be a useful molecular marker to predict the prognosis in LSCC patients. It is concluded that the expression of CD133 and KAI1/CD82 protein could be correlated with lymph node metastasis, grade of tumor, and pT/NM stage in LSCC, and also concluded that they are useful prognostic factors for OS and DFS in LSCC. The combined detection of CD133 and KAI1/CD82 can, to some extent, reflect the biological behavior of LSCC, thus giving the choice of molecular targeting therapy. However, the number of specimens in our study was relatively small. Further studies with larger sized specimens and molecular experiments are needed to verify the present observations.

Conclusions
It is suggested that CD133 and KAI1/CD82 may play an important role in the evolution of LSCC. And CD133 and KAI1/CD82 should be considered as potential marker for the prognosis in patients with LSCC.

Abbreviations
LSCC: laryngeal squamous cell carcinoma; CSC: cancer stem cells; pT/NM: pathological tumor-node-metastasis; OS: overall survival; DFS: disease free survival; TM4SF: tetraspan transmembrane superfamily; DAB: diaminobenzidine.

Competing interests
The authors declare that they have no competing interests.

Authors’ contributions
YL, ZL and WSW carried out the design, analysis of pathology and drafted the manuscript. GXM, FZZ, NL, ZB and VN carried out sample collections and coordination. WDN and DHM performed the immunochemical staining. All authors read and approved the manuscript.

Acknowledgments
We thank all colleagues in Department of Pathology, the First Hospital Affiliated to Bengbu Medical College for their help and support in this study. This study was partially supported by Anhui Province College Excellent Young Talents Found Project (No.2012SQRL094 and 2012SQRL095) and the Natural Science Foundation of Anhui Province (No.1208085MH152) and Education Department of Anhui General Project (KJ2011B100). All authors have contributed greatly, and all authors are in agreement with the content of the manuscript.
