Abstract

The classification of heart disease patients is of great importance in cardiovascular disease diagnosis. Numerous data mining techniques have been used so far by the researchers to aid health care professionals in the diagnosis of heart disease. For this task, many algorithms have been proposed in the previous few years. In this paper, we have studied different supervised machine learning techniques for classification of heart disease data and have performed a procedural comparison of these. We have used the C4.5 decision tree classifier, a naïve Bayes classifier, and a Support Vector Machine (SVM) classifier over a large set of heart disease data. The data used in this study is the Cleveland Clinic Foundation Heart Disease Dataset available at UCI Machine Learning Repository. We have found that SVM outperformed both naïve Bayes and C4.5 classifier, giving the best accuracy rate of correctly classifying highest number of instances. We have also found naïve Bayes classifier achieved a competitive performance though the assumption of normality of the data is strongly violated.

Keywords: Classification; Comparison; C4.5 Classifier; Naïve bayes classifier; SVM Classifier; Heart disease data

Introduction

Now-a-days, the number of people suffering from heart disease is increasing drastically. According to the World Health Organization (WHO) causes of death summary tables 2008, the total number of deaths due to cardiovascular disease has reached to 17.3 million in a year (World Bank, 2008). However, precise diagnosis at an initial phase followed by appropriate treatment can save huge amount of lives(Yan et al., 2003). Unfortunately, correct diagnosis of heart disease at a primary phase is quite a challenging task because of complex interdependence on various factors (Yan et al., 2003). Hence, there is a demanding need to develop medical diagnosis systems in such a way that can assist medical practitioners in the diagnostic process.

Precise prediction of risk factors which are associated with cardiovascular disease is critically important for the diagnosis and treatment of heart disease. In order to acquire appropriate information from the databases, biologists are using up-to-date machine learning techniques enormously. Among the existing techniques, supervised learning methods are the most popular in heart disease diagnosis (Kumaravel et al., 1996). Statistical analysis has identified some risk factors related with heart disease to be age, blood pressure, smoking habit (Heller et al., 1984), total cholesterol (Wilson et al., 1998), diabetes (Simons et al., 2011), hypertension, family history of heart disease (Din et al., 2007), obesity and lack of physical activity (Shahwan, 2010). Various data mining techniques have been used by the researchers to aid medical practitioners through better accurateness in the diagnosis of heart disease. Decision Tree, Naïve Bayes, Neural Network, Genetic Algorithm, Support Vector Machine, and direct kernel self-organizing map are some techniques used so far in the diagnosis of heart disease (Shouman et al., 2011).

In this paper, we have shown a comparison of three discrete classifiers that may be used in machine learning, namely the naïve Bayes algorithm, the C4.5 decision tree and the Support Vector Machine (SVM) classifier. Our study was inspired by the need to discover an automated method to find the most suitable machine learning technique for predicting survivability rate of heart disease patients. We used naïve Bayes, C4.5 and SVM keeping into account the high non-normality of our data (Fig. 1 and Fig. 2). Here, Fig. 1
appropriate information from the databases, biologists are medical practitioners in the diagnostic process. Medical diagnosis systems in such a way that can assist et al., because of complex interdependence on various factors (Yan 1984), total cholesterol (Wilson 1984), and depression induced fluoroscopy that ranged between 0 to 3. Here, Fig. 1 represents the histogram of variable Trestbps and Fig. 2 represents the histogram of variable thalach. Basically, these two variables are two attributes of our data set. And these two figures state that our data set has non-normal distribution. For this reason, we started using the C4.5 and the naïve Bayes classifiers and then we compare results with the SVM. Astonishingly, we have found that the naïve Bayes classifier does perform better than the C4.5, although the assumption of normality of the data is strongly violated. However, we have obtained that SVM outperformed both naïve Bayes and C4.5 classifier, giving the best accuracy rate of correctly classifying highest number of instances.

Materials and methods

C4.5 forms decision trees from a set of training data. It uses the concept of Information Entropy. To make a decision that

| Name   | Type     | Description                                      |
|--------|----------|--------------------------------------------------|
| Age    | Continuous| Age in years                                     |
| Sex    | Discrete | 1 = male, 0 = female                             |
| Cp     | Discrete | Chest pain type: 1 = typical angina, 2 = atypical angina, 3 = non -anginal pain, 4 = asymptomatic |
| Trestbps | Continuous| Resting blood pressure (in mm Hg)                |
| Chol   | Continuous| Serum cholesterol in mg/dl                      |
| Fbs    | Discrete | Fasting blood sugar > 120 mg/dl: 1 = true, 0 = false |
| Restecg| Discrete | Resting electrocardiographic result: 0 = normal, 1 = having ST-T abnormality, 2 = showing probable or define left ventricular hypertrophy by Estes’ criteria |
| Thalach| Continuous| Maximum heart rate achieved                      |
| Exang  | Discrete | Exercise induced angina: 1 = yes, 0 = no          |
| Old peak ST | Continuous| Depression induced by exercise relative to rest |
| Slope  | Discrete | The slope of the peak exercise segment: 1 = up sloping, 2 = flat, 3 = down sloping |
| Ca     | Discrete | Number of major vessels colored by fluoroscopy that ranged between 0 to 3 |
| Thal   | Discrete | 3 = normal, 6 = fixed defect, 7 = reversible defect |
| Diagnos is (num) | Discrete | Diagnosis classes: 0 = healthy, 1 = patient who is subject to possible heart disease |

Table I. Selected cleveland heart disease data set attributes
splits the data into smaller subsets, each attribute of the data is used. C4.5 examines the difference in entropy that results from choosing an attribute for splitting the data. The attribute with the highest normalized information gain is the one used to make the decision. The algorithm then recurs on the smaller sub-lists.

A Bayesian classifier is a fast-supervised classification technique and this is the appropriate classifier for extensive prediction and classification tasks on composite and incomplete data sets. Naïve Bayesian classification works better when the attributes’ values for the sessions are self-determining. The naïve Bayes classifier applies to learning tasks where each instance \( x \) is described by a conjunction of attribute values and where the target function \( f(x) \) can take on any value from some finite set \( V \) (Rish, 2011).

Support Vector Machine (SVM) is a class of supervised learning algorithms first introduced by Vapnik (Vapnik, 1995). Given a set of training samples, each marked for belonging to one or two categories, an SVM training algorithm builds a model that assigns new examples into one category or the other, making it a non-probabilistic binary linear classifier. An SVM model is a representation of the samples as points in space are mapped in such a way that the samples of the distinct categories are separated by a clear gap (i.e., as wide as possible) (Vapnik, 1995). The data used in this study is the Cleveland Clinic Foundation Heart Disease Data Set available at UCI Machine Learning Repository (Lichman, 2013 and Detrano, 1988). This data set has 76 raw attributes, but all published experiments refer to using a subset of 14 of them. In particular, Cleveland data set is the only one that has been used Machine Learning researchers to this date. Consequently, to allow comparison with the literature, we restricted testing to these 13 attributes and 1 goal attribute which are listed in Table 1. The “goal” field refers to the presence of heart disease in the patient. The data set consists of 13 numeric attributes including age, sex, chest pain type, resting blood pressure, cholesterol, fasting blood sugar, resting ECG, maximum heart rate, exercise induced angina, oldpeak, slope, number of vessels coloured and thal. The classes comprise of integers valued 0 (no presence of heart disease) and 1 (presence of heart disease).

**Results and discussion**

For clustering analysis, we had used the data set which contains 303 instances of patients and a panel of 14 attributes including the target attribute. There is basically two categories of population among 303 cases. One of them are healthy and the number of this class is 165. The other one is the patient who is subject to possible heart disease and they are in number of 138.

After loading our data in the WEKA software (Witten and Frank, 2005), we chose the C4.5 classifier algorithm. As it can handle continuous attributes, there was no need to discretize any of the attributes and in our experiments, we accepted the default values for the parameters. We chose to run the classifier 10 times using the 10-fold cross validation option and evaluate the accuracy of the obtained classification simply by looking at the percentage of the correct classify instances. Later, we used the same ‘initial conditions’ and repeated the experiments for the same number of times for running other classifiers. After that, we observed the returning results and the results we got were quite good. Precisely, we obtained 235 cases correctly classified (77.56%) and 68 (22.44%) incorrectly classified.

Later, we considered the naïve Bayes classifier and again we used the same default parameters which is based on the assumption that numeric attributes are conditionally independent. This method performed better than the previous one. It classified properly 253 instances (83.5%) out of 303 instances; 50 instances were misclassified (16.5%).

| Method | Classified | Misclassified |
|--------|------------|---------------|
| C4.5   | 235        | 68            |
|        | (77.56%)   | (22.44%)      |
| Naïve  | 253        | 50            |
| Bayes  | (83.5%)    | (16.5%)       |
| SVM    | 255        | 48            |
|        | (84.12%)   | (15.84%)      |

one must be aware that naïve Bayes relies on two fundamental assumptions: the first one is the complete independence of features and the second is that the attributes should follow a normal distribution, which is not always true (Soria et al., 2008). Considering the later assumption, it can be easily state that our data does not have a normal distribution. Though the violation of its assumption, the naïve Bayesian classifier is strangely effective on our data set, showing a good performance.

We finally applied the SVM classifier using the same default parameters leaving kernel as polykernel and tolerance parameter as 0.001. The default sequential minimal optimization algorithm was used. Comparison of alternative learning algorithms is outside the scope of this study. This method outperformed the other two significantly.
Of the 303 cases, 255 (84.12%) were classified perfectly using this method; just 48 cases (15.84%) were misclassified. The result is summarised in Table II.

**Conclusion**

In this paper, we studied three different machine learning techniques and used them over a novel data set of heart disease for classification. From our experiments, we obtained different results for each of them. Using the whole dataset (14 attributes × 303 instances), we got the best performance from the SVM classifier: in fact only 48 cases were incorrectly classified. The naïve Bayes and C4.5 returned similar results but worse than the SVM.

From the results, it can be stated that all classifiers achieved a reasonable performance. However, we found that, SVM performed significantly better than both C4.5 and naïve Bayes classifier on our data set. Future research involves more intensive testing using a larger heart disease database to get more accurate results.
