Abstract

Predictions for the ratio $M_W/m_t$ arise in top condensation models from different methods. One type of prediction stems from Pagels–Stokar relations based on the use of Ward Identities in the calculation of the Goldstone Boson decay constants and expresses $M_W$ in terms of integrals containing the dynamically generated mass function $\Sigma_t(p^2)$. Another type of prediction emerges from the renormalization group equations via infrared quasi–fixed–points of the running top quark Yukawa coupling. We demonstrate in this paper that in the limit of a high cutoff these two methods lead to the same predictions for $M_W/m_t$ and $M_W/M_H$ in lowest loop order.

I. Introduction

A composite Higgs sector might solve the theoretical problems of scalars in the Standard Model. One possibility is that the Higgs particle is essentially a top–anti-top bound state explaining naturally why the top quark Yukawa coupling and the Higgs quartic coupling are of order unity (i.e. the largeness of the top quark and Higgs masses). Instead of fundamental scalars models of top condensation \cite{1, 2} have therefore some new interaction capable of forming the required top condensate. The dynamics then generates an effective scalar sector which describes the symmetry breaking in analogy to the Ginzburg–Landau description of superconductivity. The simplest realization of the idea of top condensation, the so-called BHL model \cite{1}, consists just of the kinetic parts of the ordinary quarks, leptons and $SU(3)_c \times SU(2)_L \times U(1)_Y$ gauge fields and a new attractive four–fermion interaction. The BHL Lagrangian is

$$\mathcal{L}_{BHL} = \mathcal{L}_{\text{kinetic}} + G t_R t_R \ell R \ell L ,$$

where $\mathcal{L}_{\text{kinetic}}$ contains the kinetic terms for all gauge fields, quarks and leptons. $L^T = (t_L, b_L)$ is the third generation doublet of quarks containing the left–handed top and bottom fields and $t_R$ is the right–handed component of the top quark. The symmetry breaking of the BHL model by loop effects with a high energy cutoff $\Lambda$ can be studied in the large $N_c$ limit (where $N_c$ is the number of colors) in analogy to Nambu–Jona-Lasinio (NJL) models. For $G > G_{cr} = 8\pi^2/N_c \Lambda^2$ the gap equation is found to be critical and a top condensate emerges. The breakdown of global symmetries by this condensate implies the existence of composite Goldstone Bosons. In the NJL–treatment of the BHL model these Goldstone Bosons are found as massless poles in fermion scattering amplitudes along with a composite Higgs particle of mass $2m_t$. It turns out that this set of composite scalar fields is equivalent to the usual Standard Model Higgs doublet $\phi$ with a non–vanishing vacuum expectation value (VEV). The symmetry breaking is thus more or less identical to the Standard Model. The composite Goldstone Bosons are therefore eaten exactly as in the Standard Model and produce the usual $W$ and $Z$ mass relations.

When the $W$ mass is calculated in large $N_c$ approximation in terms of the top mass \cite{1} then one finds for $N_c = 3$

$$M_W^2 = m_t^2 \frac{3g_2^3}{32\pi^2} \ln \left( \frac{\Lambda^2}{m_t^2} \right) .$$

Low values of $\Lambda$ lead to a phenomenologically unacceptable large top mass and one is thus forced to large $\Lambda$ which requires however a fine–tuning of $G \to G_{cr}$. Since the ratio $M_W/m_t$ is so crucial for the phenomenological viability one should study improvements of the above
large $N_c$ relation. Using Ward Identities one can derive the so-called Pagels–Stokar formulae which can also be obtained directly by inserting running masses into the derivation of eq. (2). Another possibility is to use immediately the Standard Model as the effective low–energy theory of BHL. This gives constraints on the running of the Standard Model top Yukawa coupling $g_t$, which determines the top mass. In the following we will discuss how these two approaches are related and we will see that the two methods give the same results in the high cutoff limit.

II. Compositeness and the Renormalization Group

Using the auxiliary field formalism we can rewrite the four–fermion coupling term of eq. (1) with the help of a static, non propagating, scalar doublet $\varphi := -G t_R L$ of mass $G^{-1}$ such that the Lagrangian eq. (1) becomes

$$L_{aux} = L_{\text{kinetic}} - \bar{L}\varphi t_R - \bar{t}_R \varphi^\dagger L - G^{-1} \varphi^\dagger \varphi .$$

The dynamics of the original model generates further terms in the Lagrangian which depend on this scalar field $\varphi$. For large cutoff $\Lambda$ only renormalizable terms are allowed in the effective Lagrangian such that we obtain

$$L_{\text{eff}} = L_{aux} + Z_\varphi (D_\mu \varphi)^\dagger (D^\mu \varphi) + \delta M^2 \varphi^\dagger \varphi - \frac{\delta \lambda}{2} \left( \varphi^\dagger \varphi \right)^2 - \delta g_t \left( \bar{L}\varphi t_R + \bar{t}_R \varphi^\dagger L \right) + \delta L_{\text{kinetic}} .$$

Note that symmetry breaking occurs when $\delta M^2 > G^{-1}$ which is achieved for $G > G_{cr}$. Having the Wilson renormalization group approach in mind we can immediately read off those conditions which express the composite nature of the effective scalar Lagrangian $Z_\varphi \rightarrow 0$, $\delta M^2 \rightarrow 0$, and $\delta \lambda \rightarrow 0$. This expresses simply the fact that all dynamical effects must disappear as the momentum approaches the scale of new physics. Additionally we have the normalization conditions $\delta g_t \rightarrow 0$ and $\delta L_{\text{kinetic}} \rightarrow 0$. We can now use the freedom to rescale the scalar field $\varphi$ by defining $\phi := \frac{\varphi}{\sqrt{Z_\varphi}}$ such that the Lagrangian becomes

$$L_{\text{eff}} = L_{\text{kinetic}} + (D_\mu \phi)^\dagger (D^\mu \phi) + \frac{\lambda v^2}{2} \phi^\dagger \phi - \frac{\lambda}{2} \left( \phi^\dagger \phi \right)^2 - g_t \left( \bar{L}\phi t_R + \bar{t}_R \phi^\dagger L \right) .$$

Here we introduced $\frac{\lambda v^2}{2} = \frac{\delta M^2 - G^{-1}}{Z_\varphi}$, $\lambda = \frac{\delta \lambda}{Z_\varphi}$ and $g_t = \frac{1+\delta g_t}{\sqrt{Z_\varphi}}$ and the effective Lagrangian has now become the Standard Model. From the definition of $g_t$, $\lambda$ and $v$ we see that the

\footnote{We ignore the fermionic wave function contribution as it does not play any role for the constituent conditions.}
conditions of compositeness are

\[ \lim_{p^2 \to \Lambda^2} g_t^{-2}(p^2) = 0, \quad \lim_{p^2 \to \Lambda^2} \lambda(p^2) = 0, \quad \lim_{p^2 \to \Lambda^2} \frac{\lambda(p^2) v^2(p^2)}{2g_t^2(p^2)} = -G^{-1}, \quad (6) \]

where \( \Lambda \) corresponds to the high energy cutoff of the BHL–model.

These compositeness conditions must obviously be fulfilled in any sensible non–perturbative treatment of the dynamics like the bubble approximation. Especially for large \( \Lambda \) one may impose the compositeness conditions directly on the running parameters of the effective Lagrangian (the Standard Model). Conditions (6) lead thus to constraints on the renormalization group equations of the Standard Model. Using the full one–loop \( \beta \)–functions these conditions can be studied numerically, but if we restrict ourself to lowest order \( 1/N_c \) including the QCD–running we can study the boundary conditions (6) analytically. The \( \beta \)–functions for \( N_c = 3 \) are in this approximation

\[ \frac{d}{dt} g_t^2 = \frac{1}{(4\pi)^2} \left( 6g_t^2 - 16g_3^2 \right) g_t^2, \quad (7) \]
\[ \frac{d}{dt} g_3^2 = - \frac{14}{(4\pi)^2} g_t^4, \quad (8) \]

and using eq. (6) as boundary condition we find the solutions

\[ g_t^2(p^2) = \frac{g_3^{16/7}(p^2)}{3 \left[ g_3^{2/7}(p^2) - g_3^{2/7}(\Lambda^2) \right]}, \quad (9) \]
\[ g_3^2(p^2) = \frac{g_3^2(M_Z^2)}{1 + \frac{14g_t^2(M_Z^2)}{(4\pi)^2} t}, \quad (10) \]

where \( t = \frac{1}{2} \ln \frac{p^2}{M_Z^2} \). Thus \( m_t = g_t(M_Z^2) v/\sqrt{2} \) with \( v = 246 \) GeV is predicted by eq. (9) in terms of \( \Lambda \) and \( g_3(\Lambda^2) \). In addition eq. (10) must be used to express \( g_3^2(\Lambda^2) \) by \( \Lambda \) and the known experimental input \( \alpha_3(M_Z^2) = g_3^2(M_Z^2)/(4\pi) = [0.115 - 0.125] \).

The predicted top mass is the so called “infrared quasi–fixed–point”. This means that the resulting top mass depends for large \( \Lambda \) only extremely mildly on the precise boundary condition at \( \Lambda \). This mild sensitivity can be seen explicitly by demanding \( g_t^{-2} \overset{p^2 \to \Lambda^2}{\longrightarrow} \delta \) with e.g. \( |\delta| \leq \pi^{-1} \) instead of \( g_t^{-2} \overset{p^2 \to \Lambda^2}{\longrightarrow} 0 \). Alternatively one can see that the prediction for the top mass depends only extremely weakly on \( \Lambda \) when \( g_3^2(\Lambda^2) \) in eq. (9) is expressed by \( \alpha_3(M_Z^2) \) via eq. (10).

The predictions from this renormalization group method should become more precise as \( \Lambda \) becomes larger. The reason is that the infrared quasi–fixed–point is more attractive for large
scales and that other effects like thresholds etc. should become less important compared to the renormalization group running. When using this renormalization group techniques one should however keep in mind that one assumes quietly that there are no further bound states in the spectrum.

III. Predictions from Pagels–Stokar Formulae

The dynamically generated $W$–mass is determined by the eaten composite Goldstone modes. The Goldstone Boson decay constants are essentially given by the fermion–loop self energies of the condensing fermion while the other contributions are strongly suppressed. Using Ward Identities the $W$–mass can be calculated in terms of the momentum dependent mass function of the top quark $\Sigma_t(p^2)$ with Euclidean momentum $p$. This leads to the well known Pagels–Stokar formula

$$M_W^2 = \frac{3g_2^2}{2(4\pi)^2} \int_0^{\Lambda^2} dp^2 \frac{\Sigma_t^2(p^2)}{p^2 + \Sigma_t^2(p^2)},$$

where $\Sigma_t(p^2)$ is the solution of the full gap (Schwinger–Dyson) equation. The top mass is defined at an Euclidean scale $M_Z$ as

$$m_t = \Sigma_t(M_Z^2).$$

It is possible to understand the origin of the dynamically generated mass function $\Sigma_t(p^2)$ in different pictures. First $\Sigma_t(p^2)$ can be viewed as the solution of a Schwinger–Dyson equation of the underlying theory (e.g. Topcolor or another renormalizable model). Alternatively $\Sigma_t(p^2)$ can be described in terms of the effective Lagrangian plus additional “residual” effects of the underlying theory. Such residual effects should however show up only at $p^2 = \mathcal{O}(\Lambda^2)$. This is a consequence of the decoupling theorems in renormalizable theories and a necessary condition for interpreting the Standard Model as an effective theory of top condensation. For $p^2 \ll \Lambda^2$ the mass function $\Sigma_t(p^2)$ should therefore be described very well by the effective Lagrangian.

In the framework of gap equations one can see this by understanding the full Standard Model top mass function as the solution of a Schwinger–Dyson equation (see fig. 1). For simplicity we include only one loop QCD–corrections. In solving this system one regains the renormalization group running of $m_t$. Now we compare this equation with the corresponding top

\[\text{Or equivalently that all other states have mass \(\Lambda\) such that they do not contribute to the running.}\]
condensation Schwinger–Dyson equation (see fig. 2). The residual effects of the former discussion correspond to the difference between the effective four–fermion coupling in fig. 2 and a more complicated interaction structure. These heavy degrees of freedom can be integrated out below the heavy boson mass scale. The equations in fig. 1 and fig. 2 can be identified in one regularization scheme by fitting the bare mass in fig. 1 appropriately. The same kind of identification can also be done including scalars after a reshuffling of the perturbation series in the top condensate model (see exact renormalization group method e.g. [8]). Thus in the high cutoff limit the solution of the full gap equation \( \Sigma_t(p^2) \) fulfills the standard model renormalization group equation.

Now, interpreting the Standard Model as an effective description of a top condensation model, we identify the masses with their Standard Model definitions. For the \( W \)–mass we have \( M_W = g_2 v/2 \), the running of \( \Sigma_t \) should be connected to the corresponding renormalization group of the effective top–Yukawa coupling. A naive approach for the top mass function therefore leads to

\[
\Sigma_t(p^2) = \frac{g_t(p^2)v}{\sqrt{2}}, \tag{13}
\]
and we get from the following constituent condition from eq. (11):

\[ 1 = \frac{3}{(4\pi)^2} \int_0^{\Lambda^2} dp^2 \frac{g_t^2(p^2)}{p^2 + g_t^2(p^2)} \frac{v^2}{2} . \]  

(14)

For large \( \Lambda \) we can neglect the low energy behaviour of \( g_t(p^2) \) and replace \( \Sigma_t \) in the denominator by an infrared cutoff of the electro–weak scale:

\[ \frac{3}{(4\pi)^2} \int_{M_Z^2}^{\Lambda^2} \frac{g_t^2(p^2)}{p^2} dp^2 = 1 . \]  

(15)

If the running of \( g_t \) is fixed by the renormalization group then eq. (15) constitutes a top mass prediction since it can be used to determine the single free boundary condition. As both the infrared quasi–fixed–point prediction eq. (9) and our new prediction eq. (15) should become more precise for large \( \Lambda \) one should expect that both results are consistent or at least approximately consistent. But inserting eqs. (9) and (10) into eq. (15) leads to

\[ \frac{3}{(4\pi)^2} \int_{M_Z^2}^{\Lambda^2} \frac{g_t^2(p^2)}{p^2} dp^2 = \frac{3}{7} \int \frac{g_t^2(p^2)}{g_t^2(M_Z^2)} \frac{dg_t^2}{g_t^2} \rightarrow \infty , \]  

(16)

i.e. this consistency of the two predictions appears badly violated. The solution to this problem can be found in the scale dependence of \( \Sigma_t \). The renormalization group equation describes the change of the couplings corresponding to a simultaneous rescaling of all the outer momenta. But the contribution to \( g_t \) which stems from the Higgs line cannot contribute to \( \Sigma_t \) because there is no momentum flow into the Higgs leg which ends in the vacuum. To describe this situation correctly we introduce a new running coupling constant \( \tilde{g}_t \) which is defined by

\[ \Sigma_t = \tilde{g}_t \frac{v}{\sqrt{2}} , \]  

(17)

and does not contain wave function corrections of the Higgs (see fig. 3). The connection between \( g_t \) and \( \tilde{g}_t \) can be seen more clearly if we keep in mind that \( g_t \) is a three point function with two independent momenta. Let \( g_t(p^2, q^2) \) be the Yukawa coupling for parallel incoming top momentum \( p \) and Higgs momentum \( q \). Then \( g_t \) and \( \tilde{g}_t \) describe the renormalization group running with respect to different momentum arguments:

\[ g_t(p^2) = g_t(p^2, p^2) , \]  

(18)

\[ \tilde{g}_t(p^2) = g_t(p^2, M_Z^2) . \]  

(19)

\(^3\text{Angles between } p \text{ and } q \text{ will not be important for our purposes.}\)
This naturally implies $\tilde{g}_t(M_Z^2) = g_t(M_Z^2)$ such that the wave function of the Higgs field is normalized to one at the scale of the Higgs mass.

The renormalization group equation describes the running of $g_t$. Eq. (7) may in fact be derived by calculating

$$
\frac{d}{dt} g_t^2 = \sigma \frac{d}{d\sigma} g_t^2((\sigma p)^2, (\sigma p)^2)
$$

from the relevant diagrams. Similarly we may formally define a corresponding renormalization group equation for the newly defined quantity $\tilde{g}_t$ and calculate the corresponding $\beta$–function in large $N_c$–limit

$$
\frac{d}{dt} \tilde{g}_t^2 = \sigma \frac{d}{d\sigma} \tilde{g}_t^2((\sigma p)^2, M_Z^2) = \frac{1}{(4\pi)^2} \left(-16g_3^2\right) \tilde{g}_t^2.
$$

Figure 3: Quantum corrections to $g_t$ and $\tilde{g}_t$.

Figure 4: $g_t$ and $\tilde{g}_t$ for $g_3^2(M_Z^2) = 1.52$ and $\Lambda = 10^{17}\text{GeV}$.
We solve eq. (21) using the boundary condition \( \tilde{g}_t(M_Z^2) = g_t(M_Z^2) \) with \( g_t(M_Z^2) \) defined by eq. (9) and obtain

\[
\tilde{g}^2_t(p^2) = \frac{g_3^{16/7}(p^2)}{3 \left[ g_3^{2/7}(M_Z^2) - g_3^{2/7}(\Lambda^2) \right]} .
\] (22)

If we insert this result instead of \( g_t \) into the left hand side of eq. (15) we find

\[
\frac{3}{(4\pi)^2} \int_{M_Z^2}^{\Lambda^2} \frac{\tilde{g}_t^2(p^2)}{p^2} dp^2 = \frac{3}{7} \int \frac{g_3^2(M_Z^2)}{g_3^2(\Lambda^2)} \tilde{g}_t^2 \frac{dg_3^2}{g_3^2} = 1 .
\] (23)

Hence the Pagels–Stokar condition is fulfilled if we use correctly \( \tilde{g}_t \) instead of \( g_t \). Eq. (15) must be written therefore correctly as

\[
\frac{3}{(4\pi)^2} \int_{M_Z^2}^{\Lambda^2} \frac{\tilde{g}_t^2(p^2)}{p^2} dp^2 = 1 ,
\] (24)

and the Pagels–Stokar formula is then in perfect agreement with the corresponding renormalization group running.

There is a nice way to see this consistency of eq. (24) without explicitly inserting eq. (22). Consider the evolution of \( \tilde{g}^2_t/g_t^2 \):

\[
\frac{d}{dt} \frac{\tilde{g}^2_t}{g_t^2} = \left( \frac{\frac{d}{dt} \tilde{g}_t^2}{\tilde{g}_t^2} - \frac{\frac{d}{dt} g_t^2}{g_t^2} \right) \frac{\tilde{g}_t^2}{g_t^2} .
\] (25)

If we insert then eq. (7) and eq. (21) into eq. (25), we obtain immediately

\[
\frac{d}{dt} \frac{\tilde{g}^2_t}{g_t^2} = -\frac{6}{(4\pi)^2} \tilde{g}_t^2 .
\] (26)

According to fig. (3) this equation involves only the wave function correction of the Higgs sector and at one loop level this is just the single diagram in fig. (5).

Integrating eq. (26) leads to:

\[
\frac{\tilde{g}^2_t}{g_t^2} \bigg|_{M_Z^2}^{\Lambda^2} = -\frac{3}{(4\pi)^2} \int_{M_Z^2}^{\Lambda^2} \frac{\tilde{g}_t^2 dp^2}{p^2} .
\] (27)

Since the compositeness condition requires a pole for \( g_t \) while eq. (21) implies that \( \tilde{g}_t \) tends to zero we find that \( \tilde{g}_t^2/g_t^2 \) goes to zero at \( \Lambda \). Together with the normalization condition
\( \tilde{g}_t(M_Z) = g_t(M_Z) \) one obtains therefore exactly the result eq. (23) without making use of explicit solutions of the renormalization group equations. In this way we can even add other terms or new interactions which contribute to \( g_t \) and \( \tilde{g}_t \) but do not change the Higgs wave function.

It is interesting that the \( W \)–mass generated by a single top–loop is consistent with the renormalization group method using only the graph in fig. (5). This can be understood by considering that the \( W \)–mass is connected to the Goldstone Boson wave function by gauge symmetry. Since custodial \( SU(2) \) symmetry is just broken by finite terms, the logarithmically divergent pieces of the Goldstone Boson wave function and the Higgs wave function must be identical. Only these logarithmically divergent terms contribute to the renormalization group equation.

IV. The Quartic Higgs Coupling

The techniques of the last sections can also be applied to the Higgs mass and the quartic Higgs coupling \( \lambda \). The renormalization group equation for \( \lambda \) is in large \( N_c \) approximation

\[
\frac{d}{dt} \lambda = \frac{12}{(4\pi)^2} g_t^2 (\lambda - \tilde{g}_t^2) .
\]

(28)

Note that the term proportional to \( \lambda^2 \) is missing because it is suppressed by \( 1/N_c \). Using the compositeness conditions eq. (6) and the above result for \( g_t \) the running \( \lambda \) is

\[
\lambda(p^2) = \frac{2 \left[ g_3^{18/7}(p^2) - g_3^{18/7}(\Lambda^2) \right]}{27 \left[ g_3^{2/7}(p^2) - g_3^{2/7}(\Lambda^2) \right]^2} .
\]

(29)

As in the case of the top Yukawa coupling we define a coupling \( \tilde{\lambda} \) which does not contain any Higgs wave function corrections (see fig. (6)):

\[
\tilde{\lambda} = \lambda \frac{\tilde{g}_t^4}{g_t^4} ,
\]

(30)
so that the renormalization group equation for $\tilde{\lambda}$ reads

$$\frac{d}{dt} \tilde{\lambda} = -\frac{12}{(4\pi)^2} \tilde{g}_t^4.$$  \hspace{1cm} (31)

We find therefore

$$\tilde{\lambda}(M_Z^2) = -\frac{\tilde{g}_t^4}{g_t} \Lambda^2 = \int \frac{d}{dt}( -\lambda) \frac{g_t^2}{2p^2} dp^2 = \frac{6}{(4\pi)^2} \int \frac{\Lambda^2 dp^2}{g_t^4 p^2}.$$  \hspace{1cm} (32)

Now we have to introduce the Standard Model Higgs mass definition. The Higgs mass function $\Sigma_H(p^2)$ which corresponds to fig. (3c) involves twice the coupling $g_t$ and twice $\tilde{g}_t$. Expressed in $\lambda$ this means:

$$\Sigma_H^2(p^2) = \frac{\tilde{g}_t^2(p^2)}{g_t^2(p^2)} v^2.$$  \hspace{1cm} (33)

With our normalization condition $g_t(M_Z^2) = \tilde{g}_t(M_Z^2)$ insertion of this mass function into eq. (32) leads to:

$$M_H^2 = \Sigma_H^2(M_Z^2) = \frac{12}{(4\pi)^2} \int \frac{\Lambda^2 \Sigma_t^2(p^2) dp^2}{g_t^4 p^2}.$$  \hspace{1cm} (34)

This is a corresponding Pagels–Stokar formula for $M_H$ which was also found by V. N. Gribov [9] for a specific case. One can directly evaluate this formula in analogy to the Pagels–Stokar calculations of the $W$–mass using the top–loop diagram with four outer Higgs lines. The

Figure 6: Quantum corrections to $\lambda$, $\tilde{\lambda}$ and $\Sigma_H$. 

\hspace{1cm} a) \hspace{1cm} H \hspace{1cm} \checkmark \hspace{1cm} H \hspace{1cm} H \hspace{1cm} H \hspace{1cm} H \hspace{1cm} H \\
\hspace{1cm} H \hspace{1cm} H \hspace{1cm} H \\
\hspace{1cm} H \hspace{1cm} H \hspace{1cm} H

\hspace{1cm} b) \hspace{1cm} H \hspace{1cm} \checkmark \hspace{1cm} H \hspace{1cm} H \hspace{1cm} H \hspace{1cm} H \hspace{1cm} H \\
\hspace{1cm} H \hspace{1cm} H \hspace{1cm} H \\
\hspace{1cm} H \hspace{1cm} H \hspace{1cm} H

\hspace{1cm} c) \hspace{1cm} v \hspace{1cm} \checkmark \hspace{1cm} \checkmark \hspace{1cm} H \hspace{1cm} H \hspace{1cm} H \\
\hspace{1cm} H \hspace{1cm} H \hspace{1cm} H \\
\hspace{1cm} H \hspace{1cm} H \hspace{1cm} H

With our normalization condition $g_t(M_Z^2) = \tilde{g}_t(M_Z^2)$ insertion of this mass function into eq. (32) leads to:

$$M_H^2 = \Sigma_H^2(M_Z^2) = \frac{12}{(4\pi)^2} \int \frac{\Lambda^2 \Sigma_t^2(p^2) dp^2}{g_t^4 p^2}.$$  \hspace{1cm} (34)

This is a corresponding Pagels–Stokar formula for $M_H$ which was also found by V. N. Gribov [9] for a specific case. One can directly evaluate this formula in analogy to the Pagels–Stokar calculations of the $W$–mass using the top–loop diagram with four outer Higgs lines. The
outer momenta are kept at the infrared cutoff so that the Yukawa couplings can be replaced by the running \( \tilde{g}_t \) to improve the diagram. In this way one arrives at eq. (34).

We have demonstrated that the renormalization group equations lead to the same result for \( M_W \) and \( M_H \) as the direct calculation via Pagels–Stokar formulae. Moreover the behavior of \( \lambda \) and \( g_t \) at the scale \( \Lambda \) shows the real power of the renormalization group analysis for top condensation models in the following calculation. The ratio of the running Higgs and top mass squared is defined by

\[
\frac{\Sigma_H^2(p^2)}{\Sigma_t^2(p^2)} = \frac{\lambda(p^2) \frac{\tilde{g}_t^2(p^2)}{4\pi^2} v^2}{\frac{\lambda^2}{g_t^2(p^2)}} = \frac{2\lambda(p^2)}{g_t^2(p^2)} = \frac{4 \left[ g_3^{18/7}(p^2) - g_3^{18/7}(\Lambda^2) \right]}{9 g_3^{16/7}(p^2) \left[ g_3^{2/7}(p^2) - g_3^{2/7}(\Lambda^2) \right]}. \tag{35}
\]

One can easily find the square root of this ratio in the limit \( p^2 \to \Lambda^2 \):

\[
\lim_{p^2 \to \Lambda^2} \frac{\Sigma_H(p^2)}{\Sigma_t(p^2)} = 2, \tag{36}
\]

which is precisely what we expect: The binding energy goes to zero at the condensation scale so that the bound states do not exist above \( \Lambda \). This result requires the \( 1/N_c \)-expansion and does not hold in the one–loop Standard Model, which does not respect that expansion.

V. Conclusions

We studied in this paper connections between two techniques which predict mass ratios \( \frac{m_t}{M_W} \) and \( \frac{M_H}{M_W} \) in top condensation models with an effective scalar sector. One method arises from infrared quasi–fixed–points in the renormalization group running of the effective Yukawa coupling, the other from using Pagels–Stokar relations which are based on Ward Identities. We argue that for a high cutoff it should be possible to identify the top mass function in Pagels–Stokar just with the running mass function of the standard model. Nevertheless the insertion of the running Standard Model top Yukawa coupling \( g_t \) in the Pagels–Stokar formula leads to an infinite \( W \)–mass. This apparent contradiction between our two approaches comes from the fact that the top mass function \( \Sigma_t \) of the Standard Model is not controlled by the running coupling \( g_t \), but by a modified running coupling \( \tilde{g}_t \). Taking this into account we show at one loop that in the high cutoff limit the Pagels–Stokar relation and the renormalization group method are equivalent. This equivalence can be used to construct an analogous Pagels–Stokar formula for the Higgs mass by imposing corresponding boundary conditions on the renormalization group flow of the quartic Higgs coupling \( \lambda \).

11
relation was obtained by Gribov [9] in a specific model. Additionally we find the expected mass relation \( \Sigma_H = 2\Sigma_t \) at the compositeness scale \( \Lambda \).

Since the techniques which are applied in this paper are rather general we believe that our results are much more generally valid in composite Higgs models with effective Yukawa and Higgs couplings along the lines of reasoning after eq. 12.

Acknowledgments: We would like to thank E. Schnapka for useful comments on the draft version of this paper. This work is in part supported by DFG and DAAD.
