Commuting Differential Operators
of Rank 3 Associated to a Curve of Genus 2

Abstract. In this paper, we construct some examples of commuting differential operators \( L_1 \) and \( L_2 \) with rational coefficients of rank 3 corresponding to a curve of genus 2.

Key words: commuting differential operators; rank 3; genus 2

2010 Mathematics Subject Classification: 13N10; 14H45; 34L99; 37K20

1 Introduction

The study of the commutation equation

\[
[L_1, L_2] = 0
\]

of two scalar differential operators

\[
L_1 = \frac{d^n}{dx^n} + \sum_{i=0}^{n-1} f_i(x) \frac{d^i}{dx^i} \quad \text{and} \quad L_2 = \frac{d^m}{dx^m} + \sum_{j=0}^{m-1} g_j(x) \frac{d^j}{dx^j}, \quad n < m,
\]

is one of the classical problems of the theory of ordinary differential equations.

Burchnall and Chaundy in [1, 2, 3] have shown that “each pair of commuting operators \( L_1 \) and \( L_2 \) is connected by a nontrivial polynomial algebraic relation \( Q(L_1, L_2) = 0 \)”.

The equation \( Q(z, w) = 0 \) determines a smooth compact algebraic curve \( \Xi \) of finite genus \( g \). For a generic point \( P \in \Xi \), there exist common eigenfunctions \( \psi(x, P) \) on \( \Xi \) such that \( L_1 \psi = \lambda \psi \) and \( L_2 \psi = \mu \psi \). The dimension \( l \) of the space of these functions corresponding to \( P \in \Xi \) is called the rank of the commuting pair \( (L_1, L_2) \). For simplicity, in this paper we denote “the commuting differential operators of rank \( l \) corresponding to a curve of genus \( g \)” by “\((l, g)\)-operators”.

Burchnall and Chaundy also made significant progress in solving the commutation equation for relatively prime orders \( m \) and \( n \). In this case, the rank \( l \) equals to 1. The study of this case was completed by Krichever [11, 12], who also obtained explicit formulas of the function \( \psi \) and the coefficients of \( L_1 \) and \( L_2 \) in terms of the Riemann \( \Theta \)-function. Let us remark that there are several papers related to this case, for instance [5, 6, 23, 25, 28, 29].

But for high rank case i.e. \( l > 1 \), it is much more complicated. In [10], the problem of classifying \((l, g)\)-operators was solved by reducing the computation of the coefficients to a Riemann problem. In [13, 14] I.M. Krichever and S.P. Novikov developed a method of deforming the Tyurin parameters on the moduli space of framed holomorphic bundles over algebraic curves. By using this method, in certain cases the Riemann problem can be avoided and they found
all \((2, 1)\)-operators. Let us remark that J. Dixmier in [4] also discovered an example of \((2, 1)\)-operators with polynomial coefficients. Furthermore, P.G. Grinevich found the condition of \((2, 1)\)-operators with rational coefficients [7]. S.P. Novikov and P.G. Grinevich [24] clarified the spectral data related to formally self-adjoint \((2, 1)\)-operators. In [21] O.I. Mokhov obtained all \((3, 1)\)-operators. A.E. Mironov in [17, 19] introduced a \(\sigma\)-invariance to simplify the Krichever–Novikov system [14] and constructed some examples of \((2, 2)\)-operators, \((2, 4)\)-operators with polynomial coefficients and also in [18, 20] formally self-adjoint \((2, g)\)-operators and \((3, g)\)-operators. Recently, an interesting paper is due to O.I. Mokhov in [22] who constructed examples of \((2k, g)\)-operators and \((3k, g)\)-operators with polynomial coefficients for arbitrary genus \(g\).

The aim of this paper is to construct examples of commuting differential operators \(L_1\) and \(L_2\) with rational coefficients of rank 3 corresponding to a curve of genus 2, which is different from those in [22].

2 The commuting operators of rank 3 and genus 2

In this section we want to construct \((3, 2)\)-operators. The first step is to use a \(\sigma\)-invariance, due to A.E. Mironov [17], to simplify the Krichever–Novikov system (2). The second step is to solve the simplified system by making a crucial hypothesis

\[
\gamma_1 = \gamma, \quad \gamma_2 = a \gamma, \quad \gamma_3 = \bar{a} \gamma, \quad a = \frac{-1 + \sqrt{3}i}{2}.
\]

The last step is to construct the commuting differential operators \(L_1\) and \(L_2\).

2.1 The general principle

Let \(\Gamma\) be a curve of genus 2 defined in \(\mathbb{C}^2\) by the equation

\[
w^2 = z^6 + c_5 z^5 + c_4 z^4 + c_3 z^3 + c_2 z^2 + c_1 z + c_0.
\]

On the curve \(\Gamma\), there is a holomorphic involution

\[
\sigma : \Gamma \to \Gamma \quad \text{by} \quad \sigma(z, w) = (z, -w),
\]

which has six fixed ramification points. It induces an action on the space of function by \((\sigma f)(x, P) = f(x, \sigma(P))\). Let us take \(q = (0, \sqrt{c_0}) \in \Gamma\). For a generic point \(P \in \Gamma\) there exist common eigenfunctions \(\psi_j(x, P), \ j = 0, 1, 2\) with an essential singularity at \(q\), of the operators \(L_1\) and \(L_2\). Without loss of generality, we assume that \(\psi_j(x, P)\) are normalized by

\[
\frac{d^i}{dx^i} \psi_j(x_0, P) = \delta_{ij},
\]

where \(x_0\) is a fixed point. Notice that on \(\Gamma - \{q\}\), \(\psi_j(x, P)\) are meromorphic and have six simple poles at \(P_1, \ldots, P_6\) independent of \(x\). Let us consider the Wronskian matrix

\[
\Psi(x, P; x_0) = \begin{pmatrix} \psi_0 & \psi_1 & \psi_2 \\ \psi'_0 & \psi'_1 & \psi'_2 \\ \psi''_0 & \psi''_1 & \psi''_2 \end{pmatrix},
\]

of the vector-valued function \(\Psi(x, P; x_0)\), and

\[
\Psi_2 \Psi^{-1} = \begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ \chi_0 & \chi_1 & \chi_2 \end{pmatrix}, \tag{1}
\]
where $\chi_j = \chi_j(x, P)$ are independent of $x_0$ and meromorphic functions on $\Gamma$ with six poles at $P_1(x), \ldots, P_6(x)$ coinciding with the poles of $\psi_j(x, P)$ at $x = x_0$. In a neighborhood of $q$, the functions $\chi_j(x, P)$ have the form

$$
\chi_0(x, P) = k + w_0(x) + O(k^{-1}), \quad \chi_1(x, P) = w_1(x) + O(k^{-1}),
$$
$$
\chi_2(x, P) = O(k^{-1}),
$$

where $k^{-1}$ is a local parameter near $q$. The expansion of $\chi_j$ in a neighborhood of the pole $P_i(x)$ has the form

$$
\chi_j(x, P) = -\frac{\gamma_i'(x) \alpha_{ij}(x)}{k - \gamma_i(x)} + d_{ij}(x) + O(k - \gamma_i(x)), \quad \alpha_{i2} = 1,
$$

where $k - \gamma_i(x)$ is a local parameter near $P_i(x)$ for $1 \leq i \leq 6$ and $0 \leq j \leq 2$.

Lemma 2.1 ([11]). The parameters $\gamma_i(x), \alpha_{ij}(x)$ and $d_{ij}(x)$, $1 \leq i \leq 6$, $0 \leq j \leq 2$ satisfy the system

$$
\text{Eq}[i, 0] := \alpha_{i0}(x)\alpha_{i1}(x) + \alpha_{i0}(x)d_{i2}(x) - \alpha'_{i0}(x) - d_{i0}(x) = 0,
$$
$$
\text{Eq}[i, 1] := \alpha_{i1}(x)^2 - \alpha_{i0}(x)\alpha_{i1}(x)d_{i2}(x) - \alpha'_{i1}(x) - d_{i1}(x) = 0.
$$

(4)

2.2 Explicit forms of $\chi_j(x, P)$

In this subsection, we discuss explicit forms of $\chi_j(x, P)$ corresponding to the curve $\Gamma$ defined by $w^2 = 1 + c_3 z^3 + c_4 z^4 + z^6$. In order to do this, we assume that

$$
\sigma \chi_2(x, P) = \chi_2(x, P), \quad \sigma P_s(x) = P_{s+3}(x), \quad s = 1, 2, 3,
$$

(5)

and

$$
\gamma_1 = \gamma, \quad \gamma_2 = a\gamma, \quad \gamma_3 = \bar{a}\gamma, \quad a = \frac{-1 + \sqrt{3}i}{2}.
$$

(6)

Theorem 2.2. Let $\gamma$ be a solution of

$$
1 + c_3 \gamma^3 + \gamma^6 - 6(-3)^{\frac{1}{3}} c_4^2 \gamma^2 = 0,
$$

(7)

then functions $\chi_0, \chi_1, \chi_2$ are given by the formulas

$$
\chi_2(x, P) = -\sum_{s=1}^{3} \frac{\gamma'_s}{z - \gamma_s} - \sum_{s=1}^{3} \frac{\gamma'_s}{\gamma_s} = \frac{3z^3\gamma'}{\gamma^4 - z^3\gamma},
$$
$$
\chi_1(x, P) = \tau_1 - \sum_{s=1}^{3} \frac{G_s \gamma'_s}{z - \gamma_s} + w(z)h_1 \frac{2(z - \gamma_1)(z - \gamma_2)(z - \gamma_3)}{(z - \gamma_1)(z - \gamma_2)(z - \gamma_3)},
$$
$$
\chi_0(x, P) = \frac{\tau_0}{2} + \frac{1}{2z} - \sum_{s=1}^{3} \frac{H_s \gamma'_s}{z - \gamma_s} - \frac{w(z)(\gamma_1 \gamma_2 \gamma_3 + zh_0)}{2z(z - \gamma_1)(z - \gamma_2)(z - \gamma_3)},
$$

(8)

with $G_s, H_s, \tau_0, \tau_1$ defined in (9)–(14).

Proof. By using the $\sigma$-invariance of $\chi_2(x, P)$, we know

$$
\gamma_s(x) = \gamma_{s+3}(x), \quad d_{s2}(x) = d_{s+3,2}(x), \quad s = 1, 2, 3.
$$
According to the properties of $\chi_j(x, P)$ in (2), (3) and (5), we could assume that the functions $\chi_j(x, P)$ are of the form in (8) with unknown functions $G_s = G_s(x)$, $H_s = H_s(x)$, $\tau_r = \tau_r(x)$ and $h_r = h_r(x)$ for $s = 1, 2, 3$ and $r = 0, 1$.

Substituting (6) into (8), we have

$$\chi_2(x, P) = \frac{3z^3\gamma'}{\gamma^4 - z^3\gamma},$$

which yields that

$$d_{i2} = -\frac{2\gamma'}{\gamma}, \quad i = 1, \ldots, 6.$$  

For simplicity we use the following notations

$$a_1 = 1, \quad a_2 = a, \quad a_3 = \bar{a}, \quad a_{s+3} = a_s, \quad G_{s+3} = G_s, \quad H_{s+3} = H_s, \quad s = 1, 2, 3.$$  

It follows from (3) that

$$\alpha_{s0} = H_s + \frac{w(a_s \gamma)h_0}{6\gamma^2\gamma'} + \frac{a_s^2 w(a_s \gamma)}{6\gamma'}, \quad \alpha_{s1} = G_s - \frac{w(a_s \gamma)h_1}{6\gamma^2\gamma'},$$

$$d_{s0} = \frac{7}{2} + \frac{a_s^2}{2\gamma} + \frac{\gamma'}{2\gamma} \sum_{m=1}^{2} (1 - a_s^2 a_{s+m}) H_{s+m}$$

$$+ \frac{(h_0 + 2(a_s \gamma)^2)w(a_s \gamma) - (h_0 + (a_s \gamma)^2) a_s \gamma w'(a_s \gamma)}{6\gamma^3},$$

$$d_{s1} = \tau_r - \frac{G_{s+1}\gamma'}{(a_s - a_{s+1})\gamma} - \frac{G_{s+2}\gamma'}{(a_s - a_{s+2})\gamma} + \frac{(a_s \gamma w'(a_s \gamma) - w(a_s \gamma))h_1}{6\gamma^3},$$

$$\alpha_{s+3,r} = \sigma \alpha_{sr}, \quad d_{s+3,1} = \sigma d_{s1}, \quad r = 0, 1, \quad s = 1, 2, 3.$$  

By substituting $\alpha_{ij}$ and $d_{ij}$ into (4), we get twelve equations

$$\text{Eq}[i, 0] = 0, \quad \text{Eq}[i, 1] = 0, \quad i = 1, \ldots, 6.$$  

We now try to solve these equations. Firstly, it follows from

$$\text{Eq}[s + 3, 1] - \text{Eq}[s, 1] = 0, \quad s = 1, 2, 3$$

that

$$G_s = \frac{h_1' - h_0 - (a_s \gamma)^2}{2h_1} + \frac{\gamma'}{2\gamma} - \frac{\gamma''}{2\gamma'}, \quad s = 1, 2, 3.$$  

By using (9) and $\text{Eq}[s + 3, 0] - \text{Eq}[s, 0] = 0$, we get

$$H_s = \frac{(h_0 + (a_s \gamma)^2)h_1'}{2h_1} - \frac{7a_s^2 \gamma \gamma'}{2h_1^2} - \frac{(h_0 + (a_s \gamma)^2)^2}{2h_1^2}$$

$$- \frac{h_0 \gamma'}{2h_1 \gamma} + \frac{(h_0 + (a_s \gamma)^2) \gamma''}{2h_1 \gamma'}, \quad s = 1, 2, 3.$$  

Furthermore, by solving

$$\text{Eq}[s + 3, 1] + \text{Eq}[s, 1] = 0, \quad \text{Eq}[s + 3, 0] + \text{Eq}[s, 0] = 0,$$
we have
\[
\text{Neq}[s, 1] := -\tau_1 + \frac{h_0^2 + 6h_0(a_s\gamma)^2 + 6a_s\gamma^4 - 6h_0h'_1 - 6(a_s\gamma)^2h'_1 + 3h_1'^2}{4h_1^2} \\
+ \frac{3h_0' - h'' + 9a_s^2\gamma'}{2h_1} + \frac{3h_0\gamma' - 2h'_1\gamma'}{2h_1\gamma} + \frac{\gamma''}{2\gamma} + \frac{\gamma'''}{2\gamma}
\]
\[
- \frac{3\gamma'^2}{4\gamma^2} - \frac{\gamma''^2}{4\gamma^2} - \frac{h_1\gamma''}{2h_1\gamma} + \frac{h_1^2w(a_s\gamma)}{36\gamma^4\gamma'^2} = 0, \quad s = 1, 2, 3,
\]
and
\[
\text{Neq}[s, 0] := -\tau_0 - \frac{a_s^2}{\gamma} + \frac{4h_0'' + 16a_s^2\gamma'}{2h_1} + \frac{(3h_0' + 9a_s\gamma' - h_1')(h_0 + (a_s\gamma)^2) - 4h_0'h_1' - 13a_s^2\gamma'h_1'}{2h_1^2} \\
+ \frac{(h_0 + (a_s\gamma)^2)^3 - 6h_1'(h_0 + (a_s\gamma)^2)^2 + 5h_1'^2(h_0 + (a_s\gamma)^2)}{2h_1^3} \\
+ \frac{6h_1\gamma' - h_0\gamma'' + (3h_0^2 - 4h_0h_1')\gamma'}{2h_1\gamma''} - \frac{(h_0 + (a_s\gamma)^2)\gamma'''}{h_1\gamma'} \\
+ \frac{(h_0 + (a_s\gamma)^2)h_1\gamma''}{2h_1\gamma'^2} + \frac{h_1^2w(a_s\gamma)}{18\gamma^4\gamma'^2}, \quad s = 1, 2, 3.
\]

Let us remark that we have reduced twelve equations to six equations
\[
\text{Neq}[s, 0] = 0, \quad \text{Neq}[s, 1] = 0, \quad s = 1, 2, 3,
\]
with four unknown functions \(\tau_1, \tau_0, h_1\) and \(h_0\).

Let us take
\[
h_1 = i(-3)^\frac{3}{4}c_4^\frac{1}{4}\gamma\sqrt{\gamma'}, \quad h_0 = \frac{i(-3)^\frac{3}{4}(\gamma\gamma'' - 4\gamma'^2)}{2c_4^\frac{1}{4}\sqrt{\gamma}^3}.
\]
(12)

From \(\text{Neq}[1, 1] = 0\), we get
\[
\tau_1 = \frac{4\gamma'^2 - 9\gamma\gamma''}{2\gamma^2} + \frac{4\gamma'\gamma''' - 3\gamma''^2}{4\gamma'^2} + \frac{i(\gamma^3 - 1)^2}{4\sqrt{3}c_4^2\gamma^2\gamma'}.
\]
(13)

By using (13), we conclude that \(\text{Neq}[2, 1] = 0\) and \(\text{Neq}[3, 1] = 0\) always hold true.

From the equation \(\text{Neq}[1, 0] = 0\), we obtain
\[
\tau_0 = \frac{i(\gamma^3 - 1)^2}{\sqrt{3}c_4^2\gamma^3} - \frac{1}{\gamma} - \frac{i(\gamma^3 - 1)^2\gamma''}{4\sqrt{3}c_4^2\gamma^2\gamma'} - \frac{2i(-3)^\frac{3}{4}c_4^\frac{3}{4}\gamma^3}{27\gamma'\gamma^2} - \frac{i(-3)^\frac{3}{4}(\gamma^3 - 1)^2}{18c_4^2\gamma^2\gamma'\gamma''} \\
- \frac{3\gamma''}{\gamma} - \frac{10\gamma'\gamma''}{\gamma^2} - \frac{4\gamma'^3}{\gamma^3} + \frac{\gamma^{(4)}}{\gamma'} - \frac{5\gamma''\gamma'''}{2\gamma^2} - \frac{3\gamma''^2}{2\gamma^3} - \frac{3\gamma''^2}{2\gamma^2}. 
\]
(14)

By using (14), both \(\text{Neq}[2, 0] = 0\) and \(\text{Neq}[3, 0] = 0\) reduce to the same equation
\[
1 + c_3\gamma^3 + \gamma^6 - 6(-3)^\frac{3}{4}c_4^\frac{1}{4}\gamma^\frac{3}{4} = 0,
\]
which is exactly the equation (7). Thus we complete the proof of the theorem.
Generally, solutions of (7) are not useful for us to construct (3, 2)-operators with “good” coefficients. But when we choose \(c_3 = 2\) or \(-2\), there are rational solutions. In what follows let us suppose
\[
c_3 = -2, \quad c_4 = -\frac{\epsilon^4}{3888}, \quad \epsilon < 0.
\]
The equation (7) is rewritten as
\[
1 - 2\gamma^3 + \gamma^6 + \epsilon\gamma^2 = 0.
\]
It is easy to check that when \((x + s_0)^3 + \epsilon^2 > 0\),
\[
\gamma = \frac{x + s_0}{((x + s_0)^3 + \epsilon^2)^{1/3}}, \quad s_0 \in \mathbb{C}
\]
is a solution of (15). Without loss of generality, we set \(s_0 = 0\). In this case we would like to write \(\gamma = \gamma(x; \epsilon)\). As a corollary of Theorem 2.2, we have

**Corollary 2.3.** Let \(\gamma(x; \epsilon) = \frac{x}{(x^3 + \epsilon^2)^{1/3}}\) be a solution of (15). Then we have

\[
\chi_0(x, P) = 1 + \frac{x^3(\epsilon^2 + x^3)}{5832} + 10(z^3 - 1) + \frac{\epsilon^2 x^3 z}{216\kappa} - \frac{108w(z) + \epsilon^2 z^2}{6\kappa} - \frac{x^3 w(z)}{2\kappa z} + \frac{16\epsilon^2 z^2}{\kappa z^3},
\]
\[
\chi_1(x, P) = \frac{132\epsilon^2 z^3 - x^3[204 - 204z^3 + 108w(z) + \epsilon^2 z^2]}{12x^2\kappa}, \quad \chi_2(x, P) = -\frac{3\epsilon^2 z^3}{x\kappa},
\]
where \(\kappa = (\epsilon^2 + x^3)z^3 - x^3\) and \(w(z) = \sqrt{1 - 2z^3 - \frac{\epsilon^2}{3888}z^4 + z^6}\).

By using (16), let us expand \(\chi_j(x, P)\) in a neighborhood of \(z = 0\)

\[
\chi_0(x, P) = 1 + \frac{\epsilon^2}{216}z - \frac{2\epsilon^2}{3x^2}z^2 + O(z^3),
\]
\[
\chi_1(x, P) = \frac{\epsilon^2}{12x^2}z^2 + O(z^3), \quad \chi_2(x, P) = \frac{3\epsilon^2}{x^4} + O(z^4),
\]
where
\[
\zeta_1 = \frac{28}{x^2} - \frac{\epsilon^2 x^3 + x^6}{5832} \quad \text{and} \quad \zeta_2 = \frac{26}{x^4}.
\]

### 2.3 Commuting differential operators of rank 3

Let \(\Gamma\) be a smooth curve of genus 2 defined by the equation
\[
w^2 = 1 - 2z^3 - \frac{\epsilon^4}{3888}z^4 + z^6
\]
on the \((z, w)\)-plane.

**Theorem 2.4.** The operator \(L_1\) corresponding to the meromorphic function
\[
\lambda = \frac{1 + w(z)}{2z^3} - \frac{1}{2}
\]
on $\Gamma$ with the unique pole at $q = (0, 1)$ and $L_1\psi = \lambda\psi$ has the form

$$L_1 = \frac{d^0}{dx^0} + \sum_{n=0}^{7} f_n \frac{d^n}{dx^n},$$

(19)

where

$$f_0 = \frac{152}{243} \left( \frac{58240}{x^9} + \frac{55\epsilon^2}{e_6 x^9} - \frac{37\epsilon^4 x^3}{e_4 x^{12}} + \frac{115\epsilon^2 x^6}{e_2 x^{15}} \right),$$

$$f_1 = \frac{55\epsilon^2}{e_6 x^9} + \frac{11337408}{x^8} + \frac{55\epsilon^2}{152x} + \frac{5\epsilon^4 x^4}{2\epsilon^2 x^7} + \frac{152}{17x^{10}},$$

$$f_2 = \frac{55\epsilon^2}{e_6 x^9} + \frac{243}{73x^2} - \frac{66119763456}{x^8} + \frac{5\epsilon^4 x^4}{2\epsilon^2 x^7} + \frac{66119763456}{17x^{10}},$$

$$f_3 = \frac{243}{73x^2} - \frac{125917}{1944} + \frac{5\epsilon^4 x^4}{2\epsilon^2 x^7} + \frac{66119763456}{17x^{10}},$$

$$f_4 = -\frac{243}{73x^2} + \frac{16x^4}{243},$$

$$f_5 = -\frac{243}{73x^2} + \frac{16x^4}{243},$$

$$f_6 = \frac{243}{73x^2} + \frac{16x^4}{243},$$

$$f_7 = -\frac{78}{x^2}.$$

(20)

**Proof.** By using (1), we have

$$\psi_j'''(x, P) = \chi_2(x, P)\psi_j''(x, P) + \chi_1(x, P)\psi_j'(x, P) + \chi_0(x, P)\psi_j(x, P).$$

(21)

It follows from (21) that the equation $L_1\psi_j = \lambda(z)\psi_j$ can be rewritten as

$$Q_0(x, z)\psi_j(x, P) + Q_1(x, z)\psi_j'(x, P) + Q_2(x, z)\psi_j''(x, P) = \lambda(z)\psi_j,$$

(22)

According to the independence of $\chi_0(x, P)$, $\chi_1(x, P)$ and $\chi_2(x, P)$ at $x = x_0$, we conclude that the system (22) is equivalent to three equations

$$Q_0(x, z) = \lambda(z), \quad Q_1(x, z) = 0, \quad Q_2(x, z) = 0.$$

By expanding $Q_j(x, z)$ at $z = 0$, we have

$$0 = Q_j(x, z) - \delta_j^0\lambda(z) = Q_{j,-2}\frac{1}{z^2} + Q_{j,-1}\frac{1}{z} + Q_{j,0} + O(z).$$

Then by solving $Q_{j,-s} = 0$ for $s, j = 0, 1, 2$, we get the coefficients of $L_1$ given by

$$f_0 = -1 - \frac{4\epsilon^2}{2x^3} + \frac{3}{2x^3} - \epsilon_2\epsilon_1'\epsilon_2' - \frac{7\epsilon_2\epsilon_1''}{2x^3} + 6\epsilon_1'\epsilon_1'' + 3\epsilon_2'\epsilon_2'' + 3\epsilon_2'\epsilon_2''$$

$$\left( -\frac{e^2}{72} - 3\epsilon_2\epsilon_1' + 3\epsilon_1'' \right) + \epsilon_1'\epsilon_2''' + 2\epsilon_2\epsilon_1^{(4)} - \epsilon_1^{(6)},$$

$$f_1 = -\frac{1}{4x^2} + 6\epsilon_1'^2 + 9\epsilon_1\epsilon_1'' + 12\epsilon_1'\epsilon_2'' + 9\epsilon_1\epsilon_2'' + 3\epsilon_2'' - 3\epsilon_1' + 3\epsilon_2'$

$$+ 4\epsilon_2'\epsilon_2'' + \epsilon_2\left( -\frac{e^2}{72} - 3\epsilon_1^2 - 3\epsilon_2^2 - 3\epsilon_1' + 2\epsilon_2^{(4)} \right) - 6\epsilon_1^{(5)} - \epsilon_2^{(6)},$$

$$f_2 = 3\left[ -\epsilon_2\epsilon_1' + 5\epsilon_1'\epsilon_2' + 5\epsilon_1'\epsilon_2'' - \epsilon_1'\epsilon_2' - 3\epsilon_1\epsilon_1'' + 3\epsilon_1'\epsilon_2'' + 3\epsilon_2'\epsilon_2'' - 5\epsilon_1' - 5\epsilon_2'' - 2\epsilon_2^{(5)} \right],$$

$$f_3 = \frac{e^2}{72} + 3\epsilon_1'^2 + 9\epsilon_1\epsilon_1'' + 9\epsilon_1'\epsilon_2'' + 3\epsilon_2'' - 21\epsilon_1''' - 15\epsilon_2^{(4)}.$$
\[ f_1 = 15\zeta_2\zeta_2' - \zeta_2(2(-3\zeta_1 - 9\zeta_2') + 21\zeta_2') - 18\zeta_1'' - 21\zeta_2''', \]
\[ f_5 = 3\zeta_2^2 - 9\zeta_1' - 18\zeta_2'', \quad f_6 = -3\zeta_1 - 9\zeta_2', \quad f_7 = -3\zeta_2. \]

By substituting \( \zeta_1 \) and \( \zeta_2 \) in (17) into the above formula, we obtain explicit expressions of \( f_j \) in (20).

Next we want to look for a 12th-order differential operator

\[ L_2 = \frac{d^{12}}{dx^{12}} + \sum_{m=0}^{10} g_m \frac{d^m}{dx^m}, \quad (23) \]

such that \( [L_1, L_2] = 0 \). Let us sketch out our ideas and omit tedious computations. The commutation equation \( [L_1, L_2] = 0 \) is written as

\[ 0 = \left[ \frac{d^9}{dx^9} + \sum_{n=0}^{7} f_n \frac{d^n}{dx^n}, \frac{d^{12}}{dx^{12}} + \sum_{m=0}^{10} g_m \frac{d^m}{dx^m} \right] = \sum_{k=0}^{18} W_k(f,g) \frac{d^k}{dx^k}, \quad (24) \]

which yields that

\[ W_k(f,g) = 0, \quad k = 0, \ldots, 18. \]

By using eleven equations \( W_k(f,g) = 0, k = 8, \ldots, 18 \), we could obtain explicit forms of \( g_m = h_m(x; \rho_0, \ldots, \rho_{10-m}) + \rho_{11-m} \) with integral constants \( \rho_{11-m} \). The last eight equations will determine some integral constants. For simplicity, we take all arbitrary parameters to be zero, and then obtain all coefficients \( g_j \) as follows

\[ g_0 = \frac{45660160}{x^{12}} - \frac{4928e^2_4}{729x^6} - \frac{20048}{729x^3} - \frac{605e^2_2x^3}{708588} + \frac{4553x^6}{708588} + \frac{79e^6_6x^6}{99179645184} + \frac{269e^4_4x^9}{661x^{15}} \]
\[ + \frac{16529940864}{e^6_{x^{15}}} + \frac{1156831381426176}{e^{18}_{x^{18}}} + \frac{24794911296}{289207845356544} + \frac{1156831381426176}{x^{24}}, \]
\[ g_1 = -\frac{45660160}{x^{11}} + \frac{4928e^2_4}{729x^5} + \frac{20048}{729x^2} - \frac{203e^4_4x}{2834352} + \frac{1691e^2_2x^4}{2834352} + \frac{7111x^7}{708588} \]
\[ + \frac{555e^6_6x^7}{325x^{16}} + \frac{16529940864}{e^{10}_{x^{10}}} + \frac{16529940864}{e^{13}_{x^{13}}} + \frac{49589822592}{49589822592}, \]
\[ g_2 = -\frac{27758080}{x^{10}} - \frac{182e^2_2}{27x^4} + \frac{296}{9x} - \frac{413e^2_2x^2}{5668704} + \frac{4339e^6_6x^5}{2834352} + \frac{6595x^8}{1417176} \]
\[ + \frac{3673320192}{e^{11}_{x^{11}}} + \frac{918330048}{e^{14}_{x^{14}}} + \frac{1836660096}{x^{17}}, \]
\[ g_3 = -\frac{5992}{729} - \frac{11567360}{e^6_{x^{9}}} + \frac{1028e^2_2}{729x^3} + \frac{25e^4_4x^3}{1417176} + \frac{457e^2_2x^6}{708588} + \frac{1393x^9}{1417176} \]
\[ + \frac{49589822592}{e^{12}_{x^{12}}} + \frac{16529940864}{e^{15}_{x^{15}}} + \frac{49589822592}{x^{18}}, \]
\[ g_4 = \frac{3395840}{x^8} + \frac{271e^2_2}{243} - \frac{243}{2834x} + \frac{193e^4_4x^4}{11337408} + \frac{317e^2_2x^7}{2834352} + \frac{307x^{10}}{2834352}, \]
\[ g_5 = \frac{693504}{x^7} - \frac{13e^2_2}{243} + \frac{221x^2}{e^4_{x^5}} + \frac{314928}{e^2_2x^8} + \frac{104976}{x^{11}} + \frac{157464}{157464}, \]
\[ g_6 = -\frac{167e^2_2}{972} + \frac{86464}{x^6} + \frac{316x^3}{243} + \frac{5668704}{e^{12}_{x^{12}}}, \]
\[ g_7 = -\frac{2834352}{5668704}, \]
\[ g_8 = -\frac{2834352}{5668704}, \]
\[ g_9 = -\frac{2834352}{5668704}, \]
\[ g_{10} = -\frac{2834352}{5668704}, \]
\[ g_{11} = -\frac{2834352}{5668704}, \]
\[ g_{12} = -\frac{2834352}{5668704}, \]
\[ g_{13} = -\frac{2834352}{5668704}, \]
\[ g_{14} = -\frac{2834352}{5668704}, \]
\[ g_{15} = -\frac{2834352}{5668704}, \]
\[ g_{16} = -\frac{2834352}{5668704}, \]
\[ g_{17} = -\frac{2834352}{5668704}, \]
\[ g_{18} = -\frac{2834352}{5668704}. \]
Commuting Differential Operators of Rank 3 Associated to a Curve of Genus 2

\[ g_7 = -\frac{672}{x^5} + \frac{\epsilon^2 x}{486} + \frac{109 x^4}{486}, \quad g_8 = -\frac{2856}{x^4} + \frac{\epsilon^2 x^2}{108} + \frac{x^5}{54}. \]
\[ g_9 = \frac{824}{x^3} + \frac{\epsilon^2 x^3}{1458} + \frac{x^6}{1458}, \quad g_{10} = -\frac{104}{x^2}. \] (25)

Remark 2.5. By analogy with the process of getting \( f_j \) in (20), we could obtain the above \( g_j \) in (25) by choosing another meromorphic function with a unique pole of order 4 at \( z = 0 \) on \( \Gamma \).

\[ \mu(z) = \frac{1 + w(z)}{2z^4} - \frac{1}{2z}. \]

Remark 2.6. One could find another operator \( L_3 \) of order 15 from \( [L_1, L_3] = 0 \). Furthermore as in [17], the commutative ring of differential operators generated by \( L_1, L_2 \) and \( L_3 \) is isomorphic to the ring of meromorphic functions on \( \Gamma \) with the pole at \( q = (0, 1) \).

2.4 The corresponding Burchnall–Chaundy curve

According to the Burchnall–Chaundy’s correspondence in [1, 2, 3], for each pair of commuting operators \( L_1 \) and \( L_2 \) there is a Burchnall–Chaundy curve defined by a minimal nontrivial polynomial \( Q(z, w) = 0 \) such that \( Q(L_1, L_2) = 0 \) (or \( Q(L_2, L_1) = 0 \)). Obviously, the above curve \( \Gamma \) defined by (18) is not the Burchnall–Chaundy curve for \( L_1 \) and \( L_2 \) given in (19) and (24). Actually the corresponding Burchnall–Chaundy curve \( \tilde{\Gamma} \) is given by

\[ w^3 - \frac{\epsilon^4}{15552}w^2 = z^4 + z^3, \]

that is to say,

\[ L_2^3 - \frac{\epsilon^4}{15552}L_2^2 = L_1^4 + L_1^3. \]

The curve \( \tilde{\Gamma} \) has a cuspidal singularity at \((0, 0)\). The operators \( L_1 \) and \( L_2 \) correspond to those meromorphic functions on \( \Gamma \)

\[ \lambda = \frac{1 + w(z)}{2z^3} - \frac{1}{2}, \quad \mu = \frac{1 + w(z)}{2z^4} - \frac{1}{2z} \]

defining a birational equivalence

\[ \pi: \Gamma \rightarrow \tilde{\Gamma}, \quad \pi(z, w) = (\lambda, \mu). \]

The inverse image of the cuspidal point is the point \( \sigma(q) \), where \( q = (0, 1) \in \Gamma \). In order to make \( \pi \) to be a morphism, we must complement \( \tilde{\Gamma} \) at infinity by a cuspidal point of the type \((3, 4)\), then its inverse image is the point \( q \).

3 Concluding remarks

In summary by using a \( \sigma \)-invariance to simplify the Krichever–Novikov system, we have constructed a pair of commuting differential operators \( L_1 \) in (19) and \( L_2 \) in (23) of rank 3 with rational coefficients corresponding to the singular curve \( \tilde{\Gamma} \), which is birationally equivalent to the smooth curve \( \Gamma \) of genus 2.

Let us remark that all of coefficients of \( L_1 \) and \( L_2 \) are polynomials with respect to the parameter \( \epsilon \). So if we take

\[ \mathcal{L}_1 = \lim_{\epsilon \to 0} L_1, \quad \mathcal{L}_2 = \lim_{\epsilon \to 0} L_2, \]
then

\[ [\mathcal{L}_1, \mathcal{L}_2] = 0, \quad \mathcal{L}_2^3 = \mathcal{L}_1^4 + \mathcal{L}_1^3. \]

More precisely, we have

\[ \mathcal{L}_1 = \mathcal{L}_3 - 1, \quad \mathcal{L}_2 = \mathcal{L}_4 - \mathcal{L}, \]

where

\[ \mathcal{L} = \frac{d^3}{dx^3} - \frac{26}{x^2} \frac{d}{dx} - \frac{28}{x^3} + \frac{x^6}{5832}. \]

So, when \( \epsilon = 0 \) this is a trivial example.

How about the case \( \epsilon \neq 0 \)? Let us comment that in this case, by a direct verification there is not such kind of \( \mathcal{L} \) of order 3 commuting with \( \mathcal{L}_1 \) and \( \mathcal{L}_2 \). Furthermore, according to the result in \([29]\), any rank one operator with rational coefficients whose second highest coefficient is zero has the property that the limit as \( x \) goes to \( \infty \) of the coefficients is zero. So, for example, the absence of a \( \frac{d^3}{dx^3} \) term in \( \mathcal{L}_2 \) and the \( x^6 \) in the coefficient of its \( \frac{d^2}{dx^2} \) term which means that \( \mathcal{L}_2 \) is not a rank 1 operator.

**Acknowledgments**

The author is grateful to Andrey E. Mironov for bringing the attention to this project and helpful discussions. The author also thanks referees’ suggestions and Alex Kasman for pointing some errors in the first version of this paper, Qing Chen and Youjin Zhang for their constant supports.
