ABSTRACT

Background and the purpose of the study: Bifidobacterial strains are excessively sensitive to acidic conditions and this can affect their living ability in the stomach and fermented foods, and as a result, restrict their use as live probiotic cultures. The aim of the present study was to obtain bifidobacterial isolates with augmented tolerance to simulated gastrointestinal condition using cross-protection method.

Methods: Individual bifidobacterial strains were treated in acidic environment and also in media containing bile salts and NaCl. Viability of the acid and acid-bile-NaCl tolerant isolates was further examined in simulated gastric and small intestine by subsequent incubation of the probiotic bacteria in the corresponding media for 120 min. Antipathogenic activities of the adapted isolates were compared with those of the original strains.

Results and major conclusion: The acid and acid-bile-NaCl adapted isolates showed improved viabilities significantly \((p<0.05)\) in simulated gastric fluid compared to their parent strains. The levels of reduction in bacterial count (Log cfu/ml) of the acid and acid-bile-NaCl adapted isolates obtained in simulated gastric fluid ranged from 0.64-3.06 and 0.36-2.43 logarithmic units after 120 min of incubation. There was no significant difference between the viability of the acid-bile-NaCl-tolerant isolates and the original strains in simulated small intestinal condition except for Bifidobacterium adolescentis \((p<0.05)\). The presence of 15 ml of supernatants of acid-bile-NaCl-adapted isolates and also those of the initial Bifidobacterium strains inhibited pathogenic bacterial growth for 24 hrs. Probiotic bacteria with improved ability to survive in harsh gastrointestinal environment could be obtained by subsequent treatment of the strains in acid, bile salts and NaCl environments.

Keywords: Probiotic, Bifidobacterium isolates, Simulated gastrointestinal fluid, Stress adaptation, Cross protection mechanisms

INTRODUCTION

Probiotics are defined as ‘live microbial foods which are associated with beneficial health effects on the host when ingested in appropriate amount (1). According to this definition, the viability and metabolic activity of probiotic bacteria should be maintained from production to consumption. It is generally recommended that probiotic products should contain at least \(10^7\) of live microorganisms per gram or per milliliter in order to exert their beneficial health effects (2, 3).

The harsh conditions of the gastrointestinal tract including the acidic environment of the stomach and the bile salts secreted in the duodenum are important impediments to the viability of ingested bacteria (4, 5). Therefore production of bifidobacteria with augmented adaptation to stress conditions is required in order to enhance their probiotic characteristics (4, 6).

Methods based on stress adaptation and cross protection are currently of researcher’s interests (2, 4). Most of the approaches to induce tolerance to the lethal stress circumstances include stress adaptation and cross-protection mechanisms based on exposures of bifidobacterial cells to sub-lethal stress-treatments of starvation, heat, bile, salts or acidic pH (2, 4).

The aim of the present study was to obtain bifidobacterial isolates with improved probiotic properties and augmented resistance to simulated gastrointestinal condition using cross-protection method.

MATERIAL AND METHODS

Bacterial strains and culture conditions
The bacterial strains used in this study were Bifidobacterium angulatum PTCC (Persian Type Culture Collection-Iran) 1366, Bifidobacterium animalis PTCC 1631, Bifidobacterium bifidum PTCC 1644 and Bifidobacterium adolescentis PTCC 1536. Strains were stored at -70 °C and routinely sub-cultured on MRS broth (Merck GMBH, Germany) enriched with 0.05% L-cysteine (Merck GMBH, Germany) (MRSBC), at 37°C (7). All incubations were performed in anaerobic jars (H₂/CO₂/N₂; 10:5:85, Anoxomat WS8000, Mart Microbiology, Lichtenvoorde and the Netherlands). Bacterial enumeration was conducted by plate counting of the cultures on MRSC agar (8).

Evaluation of sensitivity of Bifidobacterium strains to artificial gastrointestinal conditions
The ability of the Bifidobacterium strains to tolerate gastrointestinal transit was conducted according to the previously reported method (9). Quantities of individual strains (10⁶–10⁷ cells ml⁻¹) were incubated in sterile saline solution (0.5% w/v NaCl), containing 3 g/liter pepsin (Merck GMBH, Germany) (pH=2) at 37°C. Transit tolerance of the strains was evaluated by harvesting aliquots at different times (0, 90, and 120 min) and further plating on MRSC agar. After exposure to simulated gastric condition, cells were harvested in anaerobic jars (H₂/CO₂/N₂; 10:5:85, Anoxomat WS8000, Mart Microbiology, Lichtenvoorde and the Netherlands). Bacterial enumeration was conducted by plate counting of the cultures on MRSC agar (8).

Adaptation methods
Acid adaptation of Bifidobacterium strains
Fresh MRSBC media (pH=2) were inoculated with 1% of PBS-washed overnight cultures of the individual bifidobacterial strains. Acid-adapted isolates were recovered by plating them on MRSC agar at neutral pH after incubation at 37 °C for 16 hrs and further storage of the plates in anaerobic condition for 3 to 4 days (4).

Bile and Sodium Chloride adaptation of Bifidobacterium Strains
Cells of overnight cultures of acid-adapted isolates were harvested by centrifugation (6000 rpm, 15 min), washed with phosphate-buffered saline (PBS), and diluted in fresh MRSBC supplemented with bile salts Ox-gall; 3.0 % w/v and NaCl 10.0 % w/v. Cultures were incubated at 37°C for 24 hrs, and then the acid-bile-NaCl-adapted isolates were recovered by plating them on MRSC agar. (4).

Evaluation of tolerance of acid and acid-bile-NaCl adapted isolates to simulated gastrointestinal conditions
Survival of the acid-bile-NaCl-adapted Bifidobacterium isolates in stress environment simulating stomach and intestine were assessed while acid-adapted isolates were only challenged in simulated gastric condition. Cell suspensions of individual strains (10⁶–10⁷ cells ml⁻¹) were incubated in simulated gastric and small intestinal fluid as previously described. Aliquots were harvested at different times (0, 90, and 120 min) and bacterial counts were estimated by plating on MRSC agar media.

Pathogenic bacteria and culture conditions
The pathogenic bacteria used in this study were purchased from PTCC (Persian Type Culture Collection, Iran) and included; Eschershia coli ATCC 8739, Staphylococcus aureus ATCC 6538 and Pseudomonas aeruginosa ATCC 9027 (12). Fresh vegetative cultures of the individual bacteria were prepared by inoculating bacteria in Caso Agar Medium (Merck GMBH, Germany) and further incubation at 37°C for 24 hrs.

Phenotypic characterization of the acid-bile-NaCl-adapted Bifidobacterium isolates
Phenotypic of the acid-bile-NaCl-adapted isolates were compared with the original strains using conventional morphological as well as biochemical tests. A cocktail of biochemical tests were conducted on the acid-bile-NaCl-adapted Bifidobacterium isolates and the results were compared with those of the initial strains as well as those in the Bergey’s manual of determinative bacteriology.

Comparison of anti-pathogenic properties of Bifidobacterium strains before and after treatment
Overnight cultures of acid-bile-NaCl-adapted Bifidobacterium isolates and also those of the initial strains were centrifuged (6,000 rpm, 15 min) and supernatants were filter sterilized. Aliquots of 5 and 15 ml of supernatants of the individual bifidobacterial cultures were added to flasks containing 100 ml of Muller Hinton Broth and also 1ml of cultures of the pathogenic bacteria. Control flasks did not contain bifidobacterial supernatants. Flasks were incubated aerobically at 37°C for 24 hrs and the kinetics of growth of pathogenic bacteria were determined by taking samples in 2 hrs intervals and subsequent enumeration of bacteria using the conventional pour plate technique.

Statistical analyses
The results are average of triplicate analyzes. Statistical analysis of the data was carried out using SPSS version 11.5. Statistical significance of the difference in survival rates of the adapted isolates and the initial bifidobacterial strains in simulated gastrointestinal conditions were analyzed by t-test.
RESULTS AND DISCUSSION

There is an increasing interest in the use of Bifidobacterium probiotic strains in functional foods and pharmaceutical products. Initial experiments conducted by testing the sensitivity of the bifidobacterial strains (Table 1) showed the lack of Bifidobacterium intrinsic resistance to acidic condition such as simulated human gastric condition. The ability of the individual bifidobacteria to survive in the simulated gastrointestinal transit varied among strains. The viability of all of the untreated tested strains decreased significantly (p<0.05) in simulated gastric juice. The range of loss in viability varied from 0.7 to 4.6 logarithmic units after an incubation time of 90 min, which was the average contact time of the ingested foods with gastric materials. The reduction in bacterial counts after 120 min of incubation was however, 1.9-7.16 logarithmic units (Table 1). B. animalis and B. bifidum seemed to be the most resistant strains to the acidic pH showing reduction in the bacterial count of about 2 logarithmic units after 120 min of incubation in simulated gastric fluid. In contrast, B. adolescentis showed to be the most vulnerable strain to the simulated gastric fluid ending with about 7 logarithmic units reduction in its viability after 120 min of incubation. Previous studies conducted by other research groups also have shown that most of the bifidobacterial strains e.g. B. bifidum, B. animalis, B. infantis, B. breve, B. longum and B. adolescentis lacked the intrinsic resistance to simulated gastric conditions (pH 2.0 for 90 min) (2, 4, 9, 13). This could limit their application as probiotic oral supplement. Therefore, approaches based on stress adaptation and cross protection were applied to achieve improved adapted isolates. It has been demonstrated that exposure of B. breve to pH 5.2 protects cells against lethal pH values of 2.0–5.0 (14) and exposure of bacteria to stress factors (heat, bile salts, or acid pH) can protect them against further stress conditions (7). The viability of the bifidobacterial strains were not

affected in simulated small intestinal transit fluid and were considered intrinsically tolerant except for \textit{B. adolescentis} (Table 1).

In vitro laboratory and animal studies have shown that bifidobacteria exert antagonistic activity against pathogens (18,19). All the adapted isolates were shown to have kept their initial biochemical patterns (data not shown). Supernatants of the adapted strains were tested for their antipathogenic potentials against \textit{E. coli}, \textit{S. aureus}, \textit{Ps. aeruginosa} (Figures 1-3). The Presence of 15 ml of supernatants of acid-bile-NaCl-adapted isolates and also those of the initial Bifidobacterium strains inhibited pathogenic bacterial growth for 24 hrs while those of the 5 ml of supernatants were not affected and could only expand the lag phase of the pathogens.

**CONCLUSION**

Bifidobacteria are key representatives of probiotic bacteria in the functional foods and pharmaceutical products. The lack of their intrinsic resistance to simulated human gastric is a barrier for their appropriate probiotic action. The improved properties of acid-bile-NaCl-adapted Bifidobacterium isolates produced by prolonged exposure to acid, bile and NaCl condition indicate that this strategy may be useful to enhance the stability and functional properties of probiotic strains. Both stress adaptation and cross protection methods were used to achieve adapted bifidobacterial isolates with improved tolerance to gastrointestinal transit. The adopted strains may be used as probiotics in production of functional foods.
