SEGAL-BARGMANN TRANSFORM ON HERMITIAN SYMMETRIC SPACES AND ORTHOGONAL POLYNOMIALS

MARK DAVIDSON, GESTUR ÖLAFSSON, AND GENKAI ZHANG

ABSTRACT. Let $D = G/K$ be a complex bounded symmetric domain of tube type in a complex Jordan algebra $V$ and let $D_R = H/L \subset D$ be its real form in a formally real Euclidean Jordan algebra $J \subset V$. We consider representations of $H$ that are gotten by the generalized Segal-Bargmann transform from a unitary $G$-space of holomorphic functions on $D$ to an $L^2$-space on $D_R$. We prove that in the unbounded realization the inverse of the unitary part of the restriction map is actually the Laplace transform. We find the extension to $D$ of the spherical functions on $D_R$ and find the expansion in terms of the $L$-spherical polynomials on $D$, which are Jack symmetric polynomials. We prove that the coefficients are orthogonal polynomials in an $L^2$-space, the measure being the Harish-Chandra Plancherel measure multiplied by the symbol of the Berezin transform. We prove the difference equation and recurrence relation for those polynomials by considering the action of the Lie algebra and the Cayley transform on the polynomials on $D$.

1. INTRODUCTION

The study of various generalizations of the classical Weyl transform has attracted much interest and has been pursued for some time. As is well-known the Weyl transform maps unitarily from the $L^2$-space on $C^n = \mathbb{R}^{2n}$ onto the space of Hilbert-Schmidt operators on Fock-space, $\mathcal{F}(C^n)$, on $C^n$. The Weyl transform intertwines the natural actions of the Heisenberg group, $H_n = \mathbb{R} \times C^n$ and realizes the decomposition of $L^2(H_n)$. However, there is another model for the representation, namely, the so-called Schrödinger model, and the Segal-Bargmann transform is then a unitary map from the Schrödinger model to the Fock model intertwining the action of the Heisenberg group. The Segal-Bargmann and Weyl transforms have been studied for a long time in its connection with geometric quantization. But somewhat surprisingly their unitary properties have not been satisfactorily clarified. The unifying idea is the restriction principle, i.e. polarization of a suitable restriction map (10, 19). This idea, in turn, also unifies the so-called Wick quantization and Berezin transform in one picture, which we briefly recall.

Consider the tensor product $\mathcal{F}(C^n) \otimes \overline{\mathcal{F}(C^n)}$ realized as the space of Hilbert-Schmidt operators with integral kernels $F(z, w)$ holomorphic in $z$ and anti-holomorphic in $w$. Imbed $C^n$ into $C^n \times \overline{C^n}$, bar denoting opposite complex structure, by $z \mapsto (z, \bar{z})$. Consider the restriction mapping from $\mathcal{F}(C^n) \otimes \overline{\mathcal{F}(C^n)}$ to real analytic functions on $C^n$ taking functions $F(z, w)$ to its restriction $F(z, \bar{z})$. By taking a multiplier of the Gaussian (which is the restriction of the reproducing kernel of $\mathcal{F}(C^n)$) into account one gets a bounded injective map $R : \mathcal{F}(C^n) \otimes \overline{\mathcal{F}(C^n)} \to L^2(C^n)$ with dense image. It turns out that the adjoint $R^*$ is the Wick quantization map. Consider the polar decomposition $R^* = U \sqrt{RR^*}$. The map $U$ is the Weyl quantization and $RR^*$ is the Berezin transform. Thus the information about the Wick quantization, the Weyl quantization, and the Berezin transform are encoded in the restriction map.

It is easy to see by a similar calculation, as in 13, that by restriction of the Fock space on $C^n$ to its real form and taking the unitary part of the restriction we get the Bargmann-Segal transform. The Weyl transform from $L^2(C^n) = L^2(\mathbb{R}^n) \otimes L^2(\mathbb{R}^n)$ onto $\mathcal{F}(C^n) \otimes \overline{\mathcal{F}(C^n)}$ is the tensor product of two Bargmann-Segal transforms, obtained by considering the restriction to two different real forms. The point is then that both transforms may be considered as the unitary part of the adjoint of the

restriotion of certain holomorphic representations on various real forms of the underlying complex manifolds.

Instead of a flat complex space $\mathbb{C}^n$ we may take a bounded symmetric domain $D = G/K$ and consider the tensor product of a weighted Bergman space (so called holomorphic discrete series of $G$) with its conjugate. One may then perform the polar decomposition $R^* = U\sqrt{RR^*}$ of the restriction map $R$ and get a unitary intertwining operator $U$ from the tensor product onto $L^2(D)$. In terms of representation language this has been studied by Repka [22], and an analytic and explicit approach was started in [23]. In particular, it is realized that the analytic issues are far more subtle when one considers the tensor product of the analytic continuation of weighted Bergman spaces (30). For that purpose we need to understand the positive part in the polar decomposition, namely the square root of the Berezin transform $RR^*$. The Berezin transform in the case of weighted Bergman spaces is a positive bounded operator on $L^2(D)$ and its symbol has been calculated by Unterberger-Upmeier [24].

In [18], it is shown how to generalize those ideas to restriction maps from a reproducing Hilbert space of holomorphic function on a complex manifold $M_C$ to a totally real submanifold $M$. A particular situation is when $M_C = G/K$ is a bounded symmetric domain, the Hilbert space $\mathcal{F}(\mathbb{C}^n)$ is replaced by a weighted Bergman space, and $M = H/H\cap K$ is a totally real homogeneous submanifold. The restriction principle gives a natural way to define a Segal-Bargmann and Berezin transform. The symbol of the Berezin transform is then calculated in [22]. The same result for real tube domains and for classical domains are obtained by van Dijk and Pevner [6] and, respectively, Neretin [4].

In this paper we will use these ideas to construct and study a natural class of functions and orthogonal polynomials on real symmetric domains. We consider the simplest case when the real symmetric domain is, in the Siegel domain realization, the symmetric cone (Type A in terms of the classification of the root system, see [22]). The starting point is a unitary highest weight representation $(\pi_\nu, \mathcal{H}_\nu)$, with one dimensional minimal $K$-type, of the group $G$. We consider the restriction map to a real form $H/H\cap K$ corresponding to the symmetric cone, both for the bounded realization and the unbounded realization of $G/K$. The main difference is, that in the bounded realization we include the multiplier corresponding to the minimal $K$-type in our restriction map

$$R : \mathcal{H}_\nu \to L^2(H/H\cap K), \quad f \mapsto D_\nu f|_{H/H\cap K},$$

whereas in the unbounded realization we include this multiplier in the measure, so that the map $R : \mathcal{H}_\nu \to L^2(\Omega, d\mu_\nu)$ is now just the restriction $f \mapsto f|_\Omega$. Then in the unbounded realization the Segal-Bargmann transform turns out to be the Laplace transform (see Theorem 7.3). Considering the unitary image of an orthogonal set of $K$-finite $H\cap K$-invariant vectors in the holomorphic realization we construct a family of spherical orthogonal functions and polynomials on $H/H\cap K$. Our main result is the orthogonality relations, recurrence formulas and difference formulas for the polynomials. In the unbounded realization we get functions of the form $e^{-Tr(\omega)L_\nu(2\omega)}$ where $L_\nu$ is a polynomial which agrees with the Laguerre polynomials in the case where $G = SL(2, \mathbb{R})$ and $H/H\cap K \simeq \mathbb{R}^+$ (1). These polynomials have also been considered in [7], Chapter XV, but we here relate them to representations of $G$. In that way we derive differential equations satisfied by these polynomials (see Theorem (7.3)). Furthermore, applying the spherical Fourier transform we get an orthonormal basis of $L^2(\mathfrak{a}, |e(\lambda)|^{-2} d\lambda)^W$ and a family of orthogonal polynomials on $\mathfrak{a}^*$ (see Corollary 6.1 and Proposition 4.3). We derive recurrence formulas and difference formulas for these polynomials (see Theorems 6.4 and 4.4).

We mention that a large class of symmetric and non-symmetric polynomials satisfying various difference equations has been recently introduced by using the representation theory of affine Hecke algebras. However, as it is noted by Cherednik (1, p. 484) the meaning of the difference equations needs to be clarified. Our results provide the clarification and meaning of the orthogonality and difference relations for these orthogonal polynomials. It also reveals that the difference relations and the recurrence relations are somewhat dual to each other. We may well expect that this will be true for other types of Macdonald polynomials.

This joint project started in December 2000 as G. Zhang was visiting the Louisiana State University. In our discussions we realized that we were working on similar problems using similar ideas, except that G. Zhang was working in the bounded realization for all real tube domains, while the
first two authors were working on the restriction to the symmetric cone (Type A case) of unbounded realizations of Siegel domains. The analytic nature involved for the Type A case is somewhat richer, in particular in its connection with the Laplace transform. The treatment of types C and D requires however some different and more combinatorial methods, see [31].

Acknowledgement. We would like to thank Hjalmar Rosengren for bringing the paper [2] to our attention. The third author would also like to thank NSF for partially supporting his visit to LSU in December 2000.

2. Bounded symmetric domains, symmetric cones and Cayley transform

In this section we recall some known necessary background about bounded symmetric domains. We follow the presentation in [13]; see also [7].

2.1. Bounded symmetric domains. Let $V$ be a $d$-dimensional complex Hermitian simple Jordan algebra. Let $D \subset V$ be an irreducible bounded symmetric domain isomorphic to a tube type domain in $V$. Let $\text{Aut}(D)$ be the group of all biholomorphic automorphisms of $D$, let $\tilde{G} = \text{Aut}(D)_0$ be the connected component of the identity in $\text{Aut}(D)$, and let $K$ be the isotropy subgroup of $G$ at the point $0$. Then $G$ is semisimple and, as a Hermitian symmetric space, $D = G/K$. Furthermore, $K$ is a maximal compact subgroup of $G$. We denote by $\tilde{G}$ the connected simply connected covering group of $G$ and $K$ the pre-image of $K$ in $\tilde{G}$. Then $\tilde{K} \cong \mathbb{R} \times K_1$ where $K_1$ is a simply connected compact semisimple Lie group. We start by reviewing the basic structure theory of $\tilde{G}$ in terms of the structure of the Jordan algebra $V$. The Lie algebra $\mathfrak{g}$ of $G$ is identified with the Lie algebra $\text{aut}(D)$ of all completely integrable holomorphic vector fields on $D$ equipped with the Lie product

$$[X,Y](z) := X'(z)Y(z) - Y'(z)X(z), \quad X,Y \in \text{aut}(D), \quad z \in D.$$ 

Define $\theta : \mathfrak{g} \to \mathfrak{g}$ by $\theta(X)(z) := -X(-z)$. Then $\theta$ is a Cartan involution on $\mathfrak{g}$ and

$$\mathfrak{g}^\theta = \{ X \in \mathfrak{g} \mid \theta(X) = X \} = \mathfrak{k},$$

is the Lie algebra of $K$. Let

$$\mathfrak{p} := \{ X \in \mathfrak{g} \mid \theta(X) = -X \}.$$ 

Then $\mathfrak{g} = \mathfrak{k} \oplus \mathfrak{p}$ is the Cartan decomposition of $\mathfrak{g}$ corresponding to $\theta$. Every element in $\mathfrak{g}$ is given by a polynomial of degree at most 2, $[27]$. The Lie algebra $\mathfrak{k}_C$ corresponds to the elements of degree one and is isomorphic to a subalgebra of $\text{End}(V)$ by $T \mapsto (Tz)\frac{\partial}{\partial z}$. The identity map thus corresponds to the Euler operator

$$(2.1) \quad Z_0 := z \frac{\partial}{\partial z}.$$ 

This element is central in $\mathfrak{k}_C$ and $\text{ad}(Z_0)$ has eigenvalues $\pm 1$ on $\mathfrak{p}_C$. The $+1$-eigenspace $\mathfrak{p}^+$ corresponds to the constant polynomials and the $-1$-eigenspace $\mathfrak{p}^-$ corresponds to the polynomials of degree two. There exists a quadratic form $Q : V \to \text{End}(V,V)$ (where $\sqrt{\text{V}}$ is the space $V$ but with the opposite complex structure), such that

$$(2.2) \quad \mathfrak{p} = \{ \xi_v \mid v \in V \}, \quad \text{where} \quad \xi_v(z) := (v - Q(z)v)\frac{\partial}{\partial z}.$$ 

In the following we will identify elements in $\mathfrak{g}$ with the corresponding polynomials. Let $\{ z, \bar{v}, w \}$ be the polarization of $Q(z)v$, i.e.,

$$(2.3) \quad \{ z, \bar{v}, w \} = (Q(z+w) - Q(z) - Q(w))\bar{v}.$$ 

Then

$$(2.3) \quad \xi_v(z) = v - Q(z)v = v - \frac{1}{2}(z, \bar{v}, z).$$ 

The space $V$ with this triple product on $V \times \sqrt{\text{V}} \times V$, is a JB*-triple; $[27]$. Define $D : V \times \sqrt{\text{V}} \to \text{End}(V)$ by $D(z, \bar{v})w = \{ z, \bar{v}, w \}$. The Lie bracket of two elements $\xi_v, \xi_w \in \mathfrak{p}$ is then given by

$$(2.4) \quad [\xi_v, \xi_w] = (D(v, \bar{w}) - D(w, \bar{v})) \in \mathfrak{k}.$$ 

The group $K$ acts on $V$ by linear transformations. Furthermore,

$$z, w \mapsto (z \mid w) := \frac{1}{p} \text{Tr}D(z, \bar{w})$$

is a $K$-invariant inner product on $V$. Here $\text{Tr}$ is the trace functional on $\text{End}(V)$ and $p = p(\mathcal{D})$ is the genus of $\mathcal{D}$ (see (2.8) below). Denote by $\| \cdot \|$ the corresponding $K$-invariant operator norm on $\text{End}(V)$. Define the spectral norm $\| \cdot \|_{\text{sp}}$ on $V$ by

$$\|z\|_{\text{sp}} := \left\| \frac{1}{2}D(z, \bar{z}) \right\|^{1/2}.$$  

Then the domain $\mathcal{D}$ is realized as the open unit ball of $V$ with respect to the spectral norm, i.e.

$$\mathcal{D} = \{ z \in V \mid \|z\|_{\text{sp}} < 1 \}.$$ 

An element $v \in V$ is called a tripotent if $\{ v, \bar{v}, v \} = 2v$. Let us choose and fix a frame $\{ e_j \}_{j=1}^r$ of tripotents in $V$. The number $r$ is called the rank of $\mathcal{D}$. Define $H_j = D(e_j, \bar{e}_j) \in \mathfrak{t}_C$. The operator $D(u, \bar{u})$ has real spectrum for each $u \in V$. Hence, by (2.4), $H_j \in i\mathfrak{k}$. Furthermore, the subspace

$$\{ u \in V \mid D(u, \bar{u}) \text{ is abelian} \}$$

is abelian. Let $\mathfrak{t} = \mathfrak{t}_- \oplus \mathfrak{t}_+$ be a Cartan subalgebra of $\mathfrak{k}$ and $\mathfrak{g}$ containing $\mathfrak{t}_-$. Let $\Delta(\mathfrak{g}_C, \mathfrak{t}_C)$ be the set of roots of $\mathfrak{t}_C$ in $\mathfrak{g}_C$. Recall that a root $\alpha \in \Delta$ is called compact if $(\mathfrak{g}_C)_\alpha \subset \mathfrak{t}_C$ and non-compact if $(\mathfrak{g}_C)_\alpha \subset \mathfrak{p}_C$. Denote by $\Delta_c$ and $\Delta_n$ the set of compact, respectively, non-compact roots. Finally, we recall that two roots $\alpha \neq \pm \beta$ are called strongly orthogonal if $\alpha \pm \beta \notin \Delta(\mathfrak{g}_C, \mathfrak{t}_C)$. We choose $\gamma_j \in (\mathfrak{t}^*)_C$ so that

$$\gamma_j(H_k) = 2\delta_{jk}$$

and vanishes on $(\mathfrak{t}_+)_C$. Then $\{ \gamma_1, \ldots, \gamma_r \}$ is a maximal set of strongly orthogonal non-compact roots. We order them so that

$$\gamma_1 > \cdots > \gamma_r.$$ 

The element $e := e_1 + \cdots + e_r$ is a maximal tripotent and

$$Z_0 = \frac{1}{2}D(e, \bar{e}) = \frac{1}{2} \sum_{j=1}^r H_j,$$

where $Z_0$ corresponds to the identity map as before. In this notation the genus of $\mathcal{D}$ is given by

$$p = p(\mathcal{D}) = \frac{2d}{r}.$$ 

### 2.2. Real bounded symmetric domain.

Let $e = e_1 + \cdots + e_r$ be the maximal tripotent as before. The map $\tau : V \to V$, $\tau(v) = Q(e)\bar{v}$ is a conjugate linear involution of $V$ and induces a decomposition $V = J \oplus iJ$, where $J$ is a formally real Euclidean Jordan algebra with identity $e$. Notice that $\tau$ also defines an involution, also denoted by $\tau$, of $\mathfrak{g}$ and $G$. The involution on $G$ is simply given by $[\tau(g)](z) = \tau(g(\tau(z)))$, for $z \in \mathcal{D}$. As $\tau$ commutes with the Cartan involution $\theta$ we have the following decomposition of $\mathfrak{g}$ into eigenspaces:

$$\mathfrak{g} = \mathfrak{h} \oplus \mathfrak{q}$$

$$= \mathfrak{h}_k \oplus \mathfrak{q}_k \oplus \mathfrak{h}_p \oplus \mathfrak{q}_p$$

$$= \mathfrak{t}_k \oplus \mathfrak{t}_q \oplus \mathfrak{p}_h \oplus \mathfrak{p}_q,$$

where $\mathfrak{h}$ is the $+1$-eigenspace and $\mathfrak{q}$ is the $-1$-eigenspace of $\tau$. The index $k$ indicates intersection with $\mathfrak{k}$, etc. The restriction of $\theta$ to $\mathfrak{h}$ defines a Cartan involution on $\mathfrak{h}$ and the corresponding Cartan decomposition is $\mathfrak{h} = \mathfrak{t}_k \oplus \mathfrak{p}_h$. The space $\mathfrak{p}_q$ is then a real subspace of $\mathfrak{p}$. Recall the definition $\zeta_v(z) := v - Q(z)\bar{v}$. Then

$$\mathfrak{p}_h = \{ \zeta_v \mid v \in J \}.$$ 

Let $\mathcal{D}_R = \mathcal{D} \cap J = \mathcal{D}_\tau$. Then $\mathcal{D}_R$ is a real bounded symmetric domain. For the structure of these domains see [1] and [3]. Let

$$G(\mathcal{D}_R) = \{ g \in G \mid g(\mathcal{D}_R) = \mathcal{D}_R \}.$$
Then $G(D_R)$ is a closed subgroup of $G$ with finitely many connected components. Let $H = G(D_R)_o$ be the connected component containing the identity $1 \in G$. Since $e \in D_R$ the subgroup $\{ k \in K \mid k \cdot e = e \}$ is a maximal compact subgroup of $G(D_R)$ and equals $G(D_R) \cap K$. By replacing $G(D_R)$ by $H$ it follows that $H \cap K$ is a maximal compact subgroup of $H$ and

$$D_R = H/H \cap K = G(D_R)/G(D_R) \cap K$$

is a Riemannian symmetric space with the Bergman metric restricted to $D_R$. Moreover, it is a totally geodesic submanifold. Finally, $H = G_o = \{ a \in G \mid \tau(a) = a \}_o$. Thus $(G, H)$ is a symmetric pair. We note that the group $H$ is not semisimple since $\exp(\mathbb{R} \xi_e)$ is in the center of $H$. The group $H$ is invariant under the Cartan involution $\theta$ and $\theta|_H$ is a Cartan involution on $H$.

### 2.3. Cayley transform

In this subsection we discuss the realization of $D$ as a tube type domain $T(\Omega) = iJ + \Omega$. Let $\Omega$ be the cone of positive elements in $J$:

$$\Omega = \{ x^2 \mid x \in J, \det(x) \neq 0 \}.$$  

Then $\Omega$ is a symmetric convex cone. Let

$$T(\Omega) = iJ + \Omega = \{ w \in V \mid \Re(w) \in \Omega \}.$$

If $e - z$ is invertible in $V$ let

$$(2.9) \quad \gamma(z) = \frac{e + z}{e - z} = (e + z)(e - z)^{-1}$$

be the Cayley transform. Its inverse is

$$(2.10) \quad \gamma^{-1}(w) = (w - e)(w + e)^{-1}.$$  

The following is well known:

**Lemma 2.1.** Let the notation be as above. Then the following hold:

1. The Cayley transform $\gamma$ is a biholomorphic transformation from $D$ into the Siegel domain $T(\Omega)$.
2. The Cayley transform $\gamma : D \mapsto T(\Omega)$ maps the real form $D_R$ of $D$ onto the real form $\Omega$ of $T(\Omega)$.
3. The following diagram commutes

$$\begin{array}{ccc}
D_R & \xrightarrow{\gamma} & \Omega \\
\downarrow & & \downarrow \\
D & \xrightarrow{\gamma} & T(\Omega)
\end{array}$$

where the vertical arrows are the inclusion maps.

Notice that the Cayley transform can be realized by an element, also denoted $\gamma$, in $G_C$. In fact, there exists a $X \in q_o$ such that $\text{ad}(X)$ has eigenvalues $0, 1,$ and $-1$ and $\gamma = \exp(\frac{\pi}{4}X)$. Define $G^\gamma := \gamma G \gamma^{-1}$ and $H^\gamma = (K_C \cap G^\gamma)_o$. Then

$$(2.11) \quad G^\gamma(\Omega)_o = \{ g \in G^\gamma \mid g(\Omega) = \Omega \} = H^\gamma = \gamma H \gamma^{-1}.$$  

Let $\mathfrak{g}^\gamma := \text{Ad}(\gamma)(\mathfrak{g})$ be the Lie algebra of $G^\gamma$. We collect some important facts in the following lemmas:

**Lemma 2.2.** Let the notation be as above. Then the following holds:

$$(2.12) \quad \mathfrak{g}^\gamma = \mathfrak{h}_k + i\mathfrak{h}_p + i\mathfrak{q}_k + \mathfrak{q}_p$$

Thus $(\mathfrak{g}_o^\gamma, \mathfrak{t}^\gamma = \mathfrak{h}_k + i\mathfrak{h}_p, \mathfrak{h}^\gamma = \mathfrak{h}_k + i\mathfrak{q}_k)$ is the Riemannian dual of $(\mathfrak{g}, \mathfrak{t}, \mathfrak{h})$.

**Lemma 2.3.** With notation as above we have

$$\mathfrak{h}^\gamma = \mathfrak{t}_C \cap \mathfrak{g}^\gamma$$ and $Z_0$ is central in $\mathfrak{h}^\gamma$.  

We refer to \cite{[11]} for further information. The group $G^\gamma$ acts on $T(\Omega)$ by transforming the action of $G$:
\[ g \cdot z = \gamma((\gamma^{-1}g\gamma) \cdot (\gamma^{-1}(z))).\]
For simplicity we will sometimes write $\gamma$ for the adjoint action of $\gamma$ on $g_C$ and the conjugation with $\gamma$ in $G_C$.

2.4. Roots. In this subsection we describe the structure of restricted roots for the group $H$. Let $\xi_j = \xi_{e_j}$ and
\[ \xi = \xi_1 + \cdots + \xi_r.\]
By SU(1,1)-reduction we have the following:

**Lemma 2.4.** $\xi_j = \text{Ad}(\gamma)^{-1}(H_j)$ and $\xi = 2\text{Ad}(\gamma)^{-1}(Z_0) = -\text{Ad}(\gamma)(2Z_0)$.

Let
\[ a = \bigoplus_{j=1}^r \mathbb{R} \xi_j,\]
and define $\beta_j \in a^*$ by $\beta_j(\xi_i) = 2\delta_{ij}$. Then $a$ is maximal abelian in $h_p$. In fact, $a$ is also maximal abelian in $p$. We remark that $\gamma^2H_j = -H_j$, $\gamma(t_\Omega) = \gamma^{-1}(t_\Omega) = a$ and $\beta_j = \gamma_j \circ \text{Ad}(\gamma)$.

We will often identify $a_C$ with $C^r$ using the map $\alpha \mapsto \alpha = \alpha_1\beta_1 + \cdots + \alpha_r\beta_r$. The root system $\Delta(h,a)$ is of type $A$:
\[ \Delta(h,a) = \pm \left\{ \frac{\beta_j - \beta_k}{2} \mid 1 \leq j \neq k \leq r \right\}.\]
We fix an ordering of the roots so that $\beta_1 > \beta_2 > \cdots > \beta_r$.
Then the corresponding system $\Delta^+ = \Delta^+(h,a)$ of positive roots is given by
\[ \Delta^+ = \left\{ \frac{\beta_j - \beta_k}{2} \mid 1 \leq j < k \leq r \right\}.\]
The root spaces $h_{(\beta_j - \beta_k)/2}$ all have the same dimension which we denote by $a$. Then the half sum of the positive roots is
\[ \rho = \sum_{j=1}^r \rho_j\beta_j = \frac{a}{4} \sum_{j=1}^r ((r+1) - 2j)\beta_j.\]

**Example 2.5.** In the case of $D = \{z \in \mathbb{C} \mid |z| < 1\}$ and $G = \text{SU}(1,1)$ acting on $D$ in the usual way
\[ \left( \begin{array}{cc} \alpha & \beta \\ \bar{\beta} & \bar{\alpha} \end{array} \right) \cdot z = \frac{\alpha z + \beta}{\beta z + \bar{\alpha}} \]
our notation is:
\[ 2Z_0 = H_1 = \left( \begin{array}{cc} 1 & 0 \\ 0 & -1 \end{array} \right), \]
\[ \gamma = \frac{1}{\sqrt{2}} \left( \begin{array}{cc} 1 & 1 \\ -1 & 1 \end{array} \right) = \exp \left( \frac{\pi i}{4} \left( \begin{array}{cc} 0 & -i \\ i & 0 \end{array} \right) \right), \]
\[ \xi = \left( \begin{array}{cc} 0 & 1 \\ 1 & 0 \end{array} \right), \]
\[ D_\mathbb{R} = (-1,1), \]
\[ J = \mathbb{R}, \]
\[ \Omega = \mathbb{R}^+, \]
\[ T(\Omega) = \{z \in \mathbb{C} \mid \text{Re}(z) > 0\}. \]
2.5. Conical functions, spherical functions, and invariant polynomials. Let \( \{ e_j \}_{j=1}^r \) be the fixed frame as before. Let \( u_j := \sum_{k=1}^r e_k \), \( j = 1, \ldots, r \). Let \( V_j := \{ z \in V \mid D(u_j, u_j)z = 2z \} \). Then \( V_j \) is a Jordan \(*\)-subalgebra of \( V \) with a determinant polynomial denoted by \( \Delta_j \). We extend \( \Delta_j \) to all of \( V \) via \( \Delta_j(z) := \Delta_j(pr_{V_j}(z)) \), where \( pr_{V_j} \) is the orthogonal projection onto \( V_j \). The polynomials \( \Delta_j \) are called (principal) minors. Notice that \( \Delta_r(w) = \Delta(w) = \det(w) \). For any \( \alpha = (\alpha_1, \cdots, \alpha_r) \in \mathbb{C}^r \) consider the associated conical function ([7], p. 122):

\[
\Delta_\alpha(w) := \Delta_1^{1-\alpha_2}(w)\Delta_2^{\alpha_2-\alpha_3}(w) \cdots \Delta_r^{\alpha_r}(w), \ w \in V.
\]

Notice that if \( w = \sum_{j=1}^r w_j e_j \) then \( \Delta_\alpha(w) = \prod_{j=1}^r w_j^{\alpha_j} \). Thus the conical functions are generalizations of the power functions.

Let \( L := H \cap K \subset G \cap G^\gamma \) and define

\[
\psi_\alpha(z) := \int_L \Delta_\alpha(lz) dl, \quad z \in V.
\]

The function \( \psi_{\lambda + \rho} \) is the spherical function on \( \Omega \) corresponding to \( \lambda \) ([7], Theorem XIV. 3.1).

We identify \( (\mathbb{C}_0^\times)^r \) with \( \mathbb{C}^r \) via \( m_1\gamma_1 + \cdots + m_r\gamma_r \leftrightarrow (m_1, \ldots, m_r) \in \mathbb{C}^r \). If \( \lambda = \mathbf{m} \), where \( \mathbf{m} = (m_1, \ldots, m_r) \) is a tuple of non-negative integers such that \( m_1 \geq m_2 \geq \cdots \geq m_r \geq 0 \), then the functions \( \Delta_\lambda \) and \( \psi_\lambda \) are holomorphic polynomials on the whole space \( V \) and \( \psi_\lambda \) is \( L \)-invariant. Let \( \mathcal{P}(V) \) be the space of holomorphic polynomials on \( V \), considered as \( K \)-space by the regular action, \( k \cdot p(z) = p(k^{-1} \cdot z) \). Let

\[
\Lambda = \{ \mathbf{m} \in \mathbb{N}_0^r \mid m_1 \geq m_2 \geq \cdots \geq m_r \geq 0 \}.
\]

Then we have the well known Schmid decomposition ([24] and [7], Theorem XII.2.4).

**Lemma 2.6.** The space of polynomials \( \mathcal{P}(V) \) decomposes as a \( K \)-representation into

\[
\mathcal{P}(V) = \sum_{\mathbf{m} \in \Lambda} \mathcal{P}_\mathbf{m},
\]

where each \( \mathcal{P}_\mathbf{m} \) is of lowest weight \(-\mathbf{m} = -(m_1\gamma_1 + \cdots + m_r\gamma_r)\), with \( m_1 \geq \cdots \geq m_r \geq 0 \) being integers. In this case the polynomial \( \Delta_\mathbf{m} \) is a lowest weight vector in \( \mathcal{P}_\mathbf{m} \) and \( \psi_\mathbf{m} \) is up to constants the unique \( L \)-invariant polynomials in \( \mathcal{P}_\mathbf{m} \). In particular

\[
\mathcal{P}(V)^L = \sum_{\mathbf{m} \in \Lambda} \mathcal{C}\psi_\mathbf{m}.
\]

As \( \psi_{\lambda + \rho} \) is spherical on \( \Omega \) and because the Cayley transform commutes with the \( L \)-action we get the following lemma.

**Lemma 2.7.** Let \( \lambda \in a_\gamma^\times \). Then the spherical function \( \phi_\lambda(x) \) on the real bounded symmetric domain \( D_\mathbb{R} \) is given by

\[
\phi_\lambda(x) = \psi_{i\lambda + \rho} \left( \frac{e + x}{e - x} \right) = \psi_{i\lambda + \rho} \circ \gamma(x), \quad x \in D_\mathbb{R}.
\]

2.6. The \( \Gamma \)-function on symmetric cones. The \( H \)-invariant measure on \( \Omega \) is given by

\[
d\mu_0 = \Delta(x)^{-\frac{d}{2}} dx,
\]

where \( d = \dim_{\mathbb{R}}(J) = \dim_{\mathbb{C}}(V) \). The Gindikin-Koehler Gamma function associated with the convex, symmetric cone \( \Omega \) is defined by

\[
\Gamma_\Omega(\lambda) := \int_{\Omega} e^{-\operatorname{Tr}(x)} \Delta_\lambda(x) \Delta(x)^{-d/r} dx,
\]

The integral converges if and only if \( \operatorname{Re}(\lambda_j) > (j-1)a/2 \) for \( j = 1, 2, \ldots, r \) ([7], Theorem VII.1.1.). Moreover, the convergence is absolute and uniform on compact subsets of \( \mathbb{C}^n \). Using the identification \( a_\gamma^\times \) with \( \mathbb{C}^n \) via the map \( (\lambda_1, \ldots, \lambda_n) \leftrightarrow \lambda_1 \beta_1 + \cdots + \lambda_n \beta_n \) we have

\[
\Gamma_\Omega(\lambda) = (2\pi)^{\frac{d}{2}} \prod_{j=1}^r \Gamma \left( \lambda_j - (j - 1)\frac{a}{2} \right),
\]
where \( \Gamma \) is the usual Gamma function. In particular, it follows that \( \Gamma_\Omega \) has a meromorphic continuation to all of \( \mathfrak{a}_C^* \). We will view \( \Gamma_\Omega \) as a function on \( \mathbb{C}^+ \) and on \( \mathfrak{a}_C^* \) using our identification above. We also adopt the notation \( \beta_0 = \sum_{j=1}^{a} \beta_j \) and \( \Gamma_\Omega(\nu) = \Gamma_\Omega(\nu \beta_0) \), where \( \nu \in \mathbb{C} \). Finally, we define
\[
(\lambda)_m = \frac{\Gamma_\Omega(\lambda + m)}{\Gamma_\Omega(\lambda)}.
\]

2.7. The Laplace transform. We recall here a few facts about the Laplace transform on \( \Omega \). Let \( \mu \) be a (complex) Radon measure on \( \Omega \) such that \( x \mapsto e^{-(t|x|)} \in L^1(\Omega, d\mu) \) for all \( t \in \Omega \). Define the Laplace transform of \( \mu \) by
\[
L(\mu)(w) := \int_{\Omega} e^{-(w|x|)} d\mu(x) = \int_{\Omega} e^{-(t|x|)} e^{-i(s|x|)} d\mu(x),
\]
for \( w = t + is \in T(\Omega) \). Then \( L(\mu) \) is holomorphic on \( T(\Omega) \). In particular, if \( f \in L^1(\Omega, d\mu) \) then \( f(x) d\mu \) is a finite measure and hence \( L(f) := L(f d\mu) \) is well defined. Furthermore, if \( \nu \in \mathbb{C} \) is such that \( \text{Re}(\nu) > (r-1)\frac{d}{2} \) let \( d\mu_\nu(x) = \Delta(x)^{-d/r} dx \). Notice that \( \Delta_\nu dx = \Delta(x)^{-d/r} \). Then \( d\mu_\nu \) is a quasi-invariant measure on \( \Omega \) and the \( H \)-invariant measure corresponds to \( d\mu_0 \). If \( \nu > 0 \) is real, then we let
\[
(2.18) \quad L^2(\nu) = L^2(\Omega, d\mu_\nu).
\]
We define \( L_\nu : L_2^2(\Omega) \to \mathcal{O}(T(\Omega)) \) by
\[
L_\nu(f)(z) = L(f d\mu_\nu)(z) = \int_{\Omega} e^{-(z|x|)} f(x) d\mu_\nu(x), \quad z \in T(\Omega)
\]
Here \( \mathcal{O}(T(\Omega)) \) denotes the space of holomorphic functions on \( T(\Omega) \). We notice the following which follows directly from Proposition VII.1.2 of \( \mathbb{I} \) p. 124 by the holomorphicity of both sides in \( w \):

**Lemma 2.8.** Let \( \nu \in \mathbb{C} \) be such that \( \text{Re}(\nu) > (r-1)\frac{d}{2} \). Then for any \( w \in T(\Omega) \)
\[
L(\mu_\nu)(w) = \Gamma_\Omega(\nu) \Delta(w)^{-\nu}.
\]

2.8. Unitary highest weight representations. In this subsection we review some simple facts on scalar valued unitary highest weight representations. We restrict the discussion to what we will need later on. From now on \( v \mapsto v \) denotes conjugation with respect to the real form \( J \). Let \( \tilde{G}^\gamma \) be the universal covering group of \( G^\gamma \). Then \( \tilde{G}^\gamma \) acts on \( T(\Omega) \) by \( (g, z) \mapsto \kappa(g) \cdot z \) where \( \kappa : \tilde{G}^\gamma \to G^\gamma \) is the canonical projection. For \( \nu > 1 + a(r-1) \) let \( \mathcal{H}_\nu(T(\Omega)) \) be the space of holomorphic functions \( F : T(\Omega) \to \mathbb{C} \) such that
\[
||F||^{2}_\nu := \alpha_\nu \int_{T(\Omega)} |F(x + iy)|^2 \Delta(y)^{\nu + 2d/r} dxdy < \infty
\]
where
\[
(2.20) \quad \alpha_\nu = \frac{2^{r\nu}}{(4\pi)^d \Gamma(\nu + d/r)}.
\]
Then \( \mathcal{H}_\nu(T(\Omega)) \) is a non-trivial Hilbert space. For \( \nu \leq 1 + a(r-1) \) this space reduces to \( \{0\} \). If \( \nu = 2d/r \) this is the Bergman space. For \( g \in \tilde{G}^\gamma \) and \( z \in T(\Omega) \), let \( J_g(z) = J(g, z) \) be the complex Jacobian determinant of the action of \( \tilde{G}^\gamma \) on \( T(\Omega) \) at the point \( z \). We will use the same notation for elements \( g \in G \) and \( z \in \mathcal{D} \). Then
\[
J(ab, z) = J(a, b \cdot z) J(b, z)
\]
for all \( a, b \in \tilde{G}^\gamma \) and \( z \in T(\Omega) \). It is well known that for \( \nu > 1 + a(r-1) \) that
\[
(2.21) \quad \pi_\nu(g) f(z) = J(g^{-1}, z)^{\nu/r} f(g^{-1} \cdot z)
\]
defines a unitary irreducible representation of \( \tilde{G}^\gamma \). In \( \mathbb{I}, \mathbb{K} \) and \( \mathbb{L} \) it was shown that this unitary representation \( (\pi_\nu, \mathcal{H}_\nu(T(\Omega))) \) has an analytic continuation to the half-interval \( \nu > (r-1)\frac{d}{2} \). Here the representation \( \pi_\nu \) is given by the same formula \( (2.21) \) but the formula for the norm in \( (2.19) \) is no longer valid. We collect the necessary information from \( \mathbb{I} \) p. 260, in particular, Theorem XIII.1.1. and Proposition XIII.1.2., in the following theorem. We will give a new proof of (4) later using only part (3).
Lemma 2.10. In the following lemma, we note the

\[ (2.22) \]

\( \text{we concentrated on the unbounded realization. We will now shift our attention to the bounded} \]

\( \text{Weighted Bergman spaces on the bounded symmetric domain. In the last section} \)

\( \text{we concentrated on the unbounded realization. We will now shift our attention to the bounded} \)

realization \( \mathcal{D} \). Let

\[ (2.22) \]

\[ h(z, w) := \Delta(e - zw). \]

We note the \( h(z, w)^{-p} \) is the \( \text{Bergman kernel} \) on \( \mathcal{D} \). We collect a few well known facts about \( h(z, w) \)

in the following lemma.

Lemma 2.10. Let \( g \in G \) and \( z, w \in \mathcal{D} \). Then the following hold:

1. \( h(z, w) \) is holomorphic in the first variable and anti-holomorphic in the second variable.
2. \( h(w, z) = \overline{h(z, w)} \) for all \( z, w \in \mathcal{D} \).
3. \( h(g \cdot z, g \cdot w) = J(g, z)^{1/p} J(g, w)^{1/p} h(z, w) \). In particular, \( h(z, z) = |J(g, 0)|^{2/p} > 0 \) where \( g \in G \) is chosen such that \( g \cdot 0 = z \).
4. If \( x, y \in \mathcal{D}_R \) then \( h(x, y) > 0 \). In particular, all powers \( h(x, y)^\mu, \mu \in \mathbb{R}, x, y \in \mathcal{D}_R, \) are well defined.

Let \( h(z) = h(z, z) = \Delta(e - z\bar{z}) \). Then the measure

\[ (2.23) \]

\[ dm_\nu(z) = h(z)^{\nu-p} dz \]

is a quasi-invariant measure on \( \mathcal{D} \) and \( dm_0(z) \) is invariant. Furthermore,

\[ (2.24) \]

\[ dx = h(x)^{-p/2} dx \]

is an \( H \)-invariant measure on \( \mathcal{D}_R \). Let \( \tilde{G} \) be the universal covering group for \( G \). As for \( T(\Omega) \) there exists a Hilbert space \( \mathcal{H}_\nu(\mathcal{D}) \) of holomorphic functions \( \mathcal{D} \) with a unitary \( \tilde{G} \)-action, given by

\[ \pi_\nu(g) f(z) = J(g^{-1}, z)^{\frac{\nu}{p}} f(g^{-1} z) \]

if \( \nu > (r-1)a/2 \). Here \( z \mapsto J(g, z) \) is again the Jacobian of the action of \( G \) on \( V \). If \( \nu > 1 + a(r-1) \) then the norm on \( \mathcal{H}_\nu(\mathcal{D}) \) is given by

\[ (2.25) \]

\[ \| F \|_\nu^2 = \| F \|_{\mathcal{H}_\nu(\mathcal{D})}^2 := d_\nu \int_{\mathcal{D}} |F(z)|^2 dm_\nu(z) \]

where

\[ d_\nu = \frac{1}{\pi^d} \frac{\Gamma_\Omega(\nu)}{\Gamma_\Omega(\nu - d/r)}. \]

The constant \( d_\nu \) is chosen so that the constant function \( z \mapsto 1 \) has norm one.

Lemma 2.11. Let the notation be as above. Then the following hold:
1. If $F \in \mathcal{H}_{\nu}(T(\Omega))$ then the function

$$\pi_{\nu}(\gamma^{-1})(F)(w) = 2^{\nu} \Delta(e - w)^{-\nu} F \circ \gamma(w) = \Delta(e - w)^{-\nu} F((e + w)(e - w)^{-1})$$

belongs to $\mathcal{H}_{\nu}(\mathcal{D})$ and

$$\pi_{\nu}(\gamma^{-1}) : \mathcal{H}_{\nu}(T(\Omega)) \to \mathcal{H}_{\nu}(\mathcal{D})$$

is a linear isomorphism onto $\mathcal{H}_{\nu}(\mathcal{D})$.

2. The inverse $\pi_{\nu}(\gamma) : \mathcal{H}_{\nu}(\mathcal{D}) \to \mathcal{H}_{\nu}(T(\Omega))$ is given by

$$\pi_{\nu}(\gamma)(F)(z) = 2^{\nu} \Delta(z + e)^{-\nu} F \circ \gamma^{-1}(z) = 2^{\nu} \Delta(z + e)^{-\nu} F((z - e)(z + e)^{-1}).$$

3. Let $F \in \mathcal{H}_{\nu}(T(\Omega))$ then

$$\|\pi_{\nu}(\gamma^{-1})(F)\|_{\mathcal{H}_{\nu}(\mathcal{D})}^2 = \Gamma_{\nu}(\nu) \|F\|_{\mathcal{H}_{\nu}(T(\Omega))}^2.$$  

4. If $g \in G$ and $F \in \mathcal{H}_{\nu}(\mathcal{D})$ then

$$\pi_{\nu}(\gamma)(\pi_{\nu}(g)F) = \pi_{\nu}(\gamma g \gamma^{-1}) \pi_{\nu}(\gamma)(F).$$

5. If $\nu > (r - 1)\frac{d}{2}$ then $P(V) \subset \mathcal{H}_{\nu}(\mathcal{D})$ and $P(V)$ is dense in $\mathcal{H}_{\nu}(\mathcal{D})$.

6. If $\nu > (r - 1)\frac{d}{2}$ then the functions $\psi_m, m \in \Lambda$, form an orthogonal basis for $\mathcal{H}_{\nu}(\mathcal{D})^L$.

**Proof.** That the map is an isomorphism follows from [7], Proposition XIII,1.3. The intertwining relation in property (4) is a simple calculation and is left to the reader. \qed

In particular, it follows that ([7], Proposition XIII.1.4):

**Lemma 2.12.** The reproducing kernel of $\mathcal{H}_{\nu}(\mathcal{D})$ is given by $K_{\nu}(z, w) = h(z, w)^{-\nu} = \Delta(e - z\bar{w})^{-\nu}$.

Define the Fock-space on $V$ to be the space of holomorphic functions on $V$ such that

\begin{equation}
\|F\|_{\mathcal{F}(V)}^2 = \pi^{-d} \int_{V} |F(z)|^2 e^{-\|z\|^2} \, dz < \infty.
\end{equation}

The following result is proved by Faraut and Koranyi [6], see also [7], Proposition XI.4.1 and Proposition XIII.2.2. This will play an essential role in our work.

**Theorem 2.13.** Assume that $\nu > 1 + a(r - 1)$ and $m \geq 0$. Then the norms of $\psi_m$ in the Fock-space and weighted Bergman spaces are given by

$$\|\psi_m\|_{\mathcal{F}(V)}^2 = \frac{1}{d_m \left( \frac{d}{r} \right)_m}$$

and

$$\|\psi_m\|_{\mathcal{H}_{\nu}(\mathcal{D})}^2 = \frac{1}{d_m \left( \frac{d}{\nu} \right)_m}$$

respectively, where $d_m$ is the dimension of the space $\mathcal{P}_m$.

**Corollary 2.14.** Assume that $\nu > 1 + a(r - 1)$. Then the functions

$$\sqrt{\frac{d_m(\nu)}{d_m \left( \frac{d}{\nu} \right)_m}} \psi_m, \ m \in \Lambda$$

form an orthonormal basis for $\mathcal{H}_{\nu}(\mathcal{D})^L$.

**Proof.** This follows from Lemma 2.11, part 6, and the above Theorem. \qed
3. Berezin transform and generalized Segal-Bargmann transform for $D_R$

3.1. Restriction to $D$ of holomorphic functions on $D$. In this subsection we discuss the restriction principle for the bounded symmetric space $D_R$, $(\mathbb{H}, [17, 18, 22])$. In particular, we give an exact bound for the parameter $\nu$ such that the restriction map $R$, defined below, maps $P(V)$ into $L^2(H/L)$.

Recall that the $H$-invariant measure on $D_R$ is given by $d\eta(x) = h(x)^{-\frac{\nu}{2}}dx$. The group $H$ acts unitarily on $L^2(D_R, d\eta)$ by $g \cdot f(x) = f(g^{-1} \cdot x)$. Furthermore,

$$L^2(D_R, d\eta) \simeq_H L^2(H/L, dh)$$

where $dh$ denotes an $H$-invariant measure on $H/L$.

**Lemma 3.1.** Let $\nu \in \mathbb{R}$. Then $p(x)h(x)^{\nu/2} \in L^2(D_R, d\eta)$, for all $p \in P(V)$, if and only if $\nu > \frac{a(r-1)}{2}$.

**Proof.** Let $p \in P(V)$. As the closure of $D_R$ is compact it follows that $p$ is bounded on $D_R$. Hence it is enough to show that $h^{\nu/2} \in L^2(D_R, d\eta)$ if and only if $\nu > (r-1)\frac{\alpha}{2}$. Note that $h^{\nu/2}$ is $H$-invariant. Writing the invariant measure on $H/L$ using polar-coordinates gives for every $L$-invariant function:

$$\int_{H/L} f(h \cdot 0)dh = \int_{t_1 > t_2 > \ldots > t_r} f(\exp(\sum_{j=1}^{r} t_j \xi_j) \cdot 0) \left( \prod_{i<j} \sinh(t_i - t_j) \right)^{a} dt_1 \ldots dt_r.$$

If $G = SU(1, 1)$ then $\xi_1 = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$. Then

$$g_t := \exp(t \xi_1) = \begin{pmatrix} \cosh(t) & \sinh(t) \\ -\sinh(t) & \cosh(t) \end{pmatrix}$$

and hence

$$g_t \cdot 0 = \tanh(t)$$

A similar calculation in the general case gives:

$$\exp(\sum_{j=1}^{r} t_j \xi_j) \cdot 0 = \sum_{j=1}^{r} \tanh(t_j)e_j.$$

Thus

$$h(\exp(\sum_{j=1}^{r} t_j \xi_j) \cdot 0) = \Delta(e - \sum_{j=1}^{r} \tanh^2(t_j)e_j)$$

$$= \prod_{j=1}^{r} (1 - \tanh^2(t_j))$$

$$= \prod_{j=1}^{r} \frac{1}{\cosh^2(t_j)}.$$
3.1. Hence follows by the transformation properties of all \( i, j \) and \( a \) such that \( 1 < i < j < r \). Since \( \Phi \) and \( \Psi \) are bounded away from zero on such a set it must be that \(-2\nu + (r + 1 - 2j)a < 0 \) for each \( j = 1, \ldots, r \). This implies \( \nu > (r - 1)\frac{\nu}{2} \). □

We remark that the constant in the last lemma is exactly the same as the endpoint of the continuous set of parameters, \((\frac{2}{3}(r-1), \infty)\), for the unitary highest weight modules. Assume that \( \nu > (r - 1)\frac{\nu}{2} \). Let \( R_\nu \) be the restriction map \( R_\nu : \mathcal{H}_\nu(\mathcal{D}) \rightarrow \mathcal{C}_c(\mathcal{D}_\mathbb{R}) \) given by

\[
R_\nu f(x) = f(x)h(x)\hat{\Psi}.
\]

As \( \nu \) will be fixed most of the time, we will often write \( R \) for \( R_\nu \). Consider the restriction of the group action \( \pi_\nu \) of \( \hat{G} \) to \( \hat{H} \), where \( \hat{H} \) is the subgroup corresponding to the Lie algebra \( \mathfrak{h} \). Using the method from [7], Lemma 3.4, we can now prove the following lemma.

**Lemma 3.2.** Assume that \( \nu > (r-1)\frac{\nu}{2} \). Then the map \( R_\nu \) is a closed densely defined \( \hat{H} \)-intertwining operator from \( \mathcal{H}_\nu(\mathcal{D}) \) into \( L^2(\mathcal{D}_\mathbb{R}, d\eta) \).

**Proof.** That \( R \) intertwines the action of \( \hat{H} \) on \( \mathcal{H}_\nu(\mathcal{D}) \) and the regular action of \( \hat{H} \) on \( L^2(\mathcal{D}, d\eta) \) follows by the transformation properties of \( h(x) \). If \( F \) is a polynomial, \( RF \in L^2(\mathcal{D}_\mathbb{R}, d\eta) \) by Lemma 3.1. Hence \( R \) is densely defined. Let \( g \in C_c(\mathcal{D}_\mathbb{R}) \) and \( \epsilon > 0 \). Then there exists a polynomial \( F \) such that \( ||F - h^{-\nu/2}g||_\infty < \epsilon ||h^{\nu/2}|| \). Hence

\[
||RF - g||_2^2 = \int_{\mathcal{D}_\mathbb{R}} |h(x)^\nu| F(x) - h(x)^{-\nu/2}g(x)|^2 d\eta(x) \\
\leq \frac{\epsilon^2}{||h^{\nu/2}||^2} \int h(x)^\nu d\eta(x) = \epsilon^2
\]

Hence \( \text{Im}(R) \) is dense in \( L^2(\mathcal{D}_\mathbb{R}, d\eta) \). Finally, \( R \) is closed because point evaluations in \( \mathcal{H}_\nu(\mathcal{D}) \) are continuous. □

We can now consider the adjoint \( R^* : L^2(\mathcal{D}_\mathbb{R}, d\eta) \rightarrow \mathcal{H}_\nu(\mathcal{D}) \) as a densely defined operator.

**Theorem 3.3.** Assume that \( \nu > (r-1)\frac{\nu}{2} \). Let \( f \) be in the domain of definition of \( R^*_\nu \). Then the following holds:

1. \( R_\nu R^*_\nu f(y) = \int_{\mathcal{D}_\mathbb{R}} \frac{h(y)^{\nu/2}h(x)^{\nu/2}}{h(y, x)^{\nu/p}} f(x) d\eta(x) \).
2. If \( g \in H \), then this is the same as

\[
R_\nu R^*_\nu f(g \cdot 0) = \int_{\hat{H}} J(h^{-1}, 0)^{\nu/p} f(h) d\hat{h} = D_\nu * f(g),
\]

where \( D_\nu(h) = J(h, 0)^{\nu/p} \) is in \( L^2(\mathcal{H}/L, d\hat{h}) \) and \( D_\nu * f \) stands for the group convolution.
3. Assume that \( \nu > (r-1)a \). Then \( D_\nu \in L^1(\mathcal{D}_\mathbb{R}, d\eta) \).
4. If \( \nu > (r-1)a \). Then \( R_\nu R^*_\nu : L^2(\mathcal{D}_\mathbb{R}, d\eta) \rightarrow L^2(\mathcal{D}_\mathbb{R}, d\eta) \) is continuous with norm \( ||R_\nu R^*_\nu|| \leq ||D_\nu||_{L^1} \).
5. If \( \nu > (r-1)a \). Then \( R_\nu R^*_\nu : L^\infty(\mathcal{D}_\mathbb{R}, d\eta) \rightarrow L^\infty(\mathcal{D}_\mathbb{R}, d\eta) \) is continuous with norm \( ||R_\nu R^*_\nu|| \leq ||D_\nu||_{L^1} \).

**Proof.** (1) Let \( f \) be in the domain of definition of \( R^* \). Then \( R^* f \in \mathcal{H}_\nu(\mathcal{D}) \) and for \( w \in \mathcal{D} \) we get:

\[
R^* f(w) = (R^* f, h(\cdot, w)^{-\nu})_{\mathcal{H}_\nu(\mathcal{D})} \\
= (f, R(h(\cdot, w)^{-\nu}))_{L^2(\mathcal{D}_\mathbb{R})} \\
= \int_{\mathcal{D}_\mathbb{R}} f(x)h(x)^{\nu/2}h(w, x)^{-\nu} d\eta(x),
\]

where we have used that \( h(z, w) = h(w, z) \) (c.f. Lemma 2.11). Thus for \( y \in \mathcal{D}_\mathbb{R} \) we get:

\[
RR^* f(y) = \int_{\mathcal{D}_\mathbb{R}} f(x)h(y)^{\nu/2}h(x)^{\nu/2}h(y, x)^{-\nu} d\eta(x)
\]
which proves the first statement.

(2) Let \( g_1, g_2 \in H \). According to Lemma 2.10 we have

\[
h(g \cdot 0) = h(g \cdot 0, g \cdot 0) = J(g \cdot 0, 0)^2/p.
\]

Thus

\[
h(g_1 \cdot 0, g_2 \cdot 0) = h(g_2 g_2^{-1} g_1 \cdot 0, g_2 \cdot 0) = J(g_2, g_2^{-1} g_1 \cdot 0)^{1/p} J(g_2, 0)^{1/p},
\]

where we have used that \( J(g_2, 0) \) and \( J(g_1, 0) \) are real, and that \( h(z, 0) = 1 \) for all \( z \). The cocycle relation \( J(ab, z) = J(a, bz) J(b, z) \) gives

\[
J(g_1, 0) = J(g_2 g_2^{-1} g_1, 0) = J(g_2, g_2^{-1} g_1 \cdot 0) J(g_2^{-1} g_1, 0).
\]

Hence

\[
J(g_2, g_2^{-1} g_1 \cdot 0) = J(g_1, 0) J(g_2^{-1} g_1, 0)^{−1}.
\]

Thus the integral kernel for \( RR^∗ \) becomes

\[
\frac{h(g_1 \cdot 0)^{\nu/2} h(g_2 \cdot 0)^{\nu/2}}{h(g_1 \cdot 0, g_2 \cdot 0)^{\nu}} = \frac{J(g_1, 0)^{\nu/p} J(g_2, 0)^{\nu/p}}{J(g_1, 0)^{\nu/p} J(g_2^{-1} g_1, 0)^{\nu/p} J(g_2, 0)^{\nu/p}} = J(g_2^{-1} g_1, 0)^{\nu/p} = D_\nu(g_2^{-1} g_1)
\]

As \( D_\nu(g) = J(g, 0)^{\nu/p} = h(g \cdot 0)^{\nu/2} \) it follows by Lemma 3.1 that \( D_\nu \in L^2(H/L, dh) \).

(3) Notice that \( D_\nu^2 = D_{\nu r} \). Hence the claim follows from Lemma 3.1.

(4) and (5) are now obvious. \( \square \)

If \( \nu > a(r-1) \) then

\[
RR^∗1(g \cdot 0) = \int_H D_\nu(g^{-1} h) \, dh = ||D_\nu||_{L^1} < \infty.
\]

Since \( ||D_\nu||_{L^1} > 0 \) we define \( c_\nu \) by the relation \( \frac{1}{c_\nu} = ||D_\nu||_{L^1} \). The operator \( RR^* \) is called the Berezin transform on \( D_\nu \) and \( B_\nu = c_\nu RR^* \) is called the normalized Berezin transform because \( B_\nu(1) = 1 \). By theorem (3.3)

\[
B_\nu f(x) = c_\nu \int_{D_\nu} \frac{h(x)^{\nu/2} h(y)^{\nu/2}}{h(x, y)^{\nu}} f(y) \, d\eta(y)
\]

or

\[
B_\nu f(x) = c_\nu \int_{D_\nu} \frac{h(x)^{\nu/2} h(y)^{\nu/2}}{h(x, y)^{\nu/2}} f(y) \, d\eta(y)
\]

The space \( L^2(D_\nu, d\eta)^L \) is decomposed into a direct integral of principle series representations of \( H \) via the spherical Fourier transform

(3.3)

\[
\widehat{f}(\lambda) = \mathcal{F}(f)(\lambda) = \int_{D_\nu} f(x) \phi_\lambda(x) \, d\eta(x)
\]

or, in terms of the spectral decomposition of commuting self-adjoint operators, as a direct integral of eigenspaces of the invariant differential operators. The \( L \)-invariant eigenfunctions of \( B_\nu \) are precisely the spherical functions \( \phi_\lambda, \lambda \in a_\nu^* \). Thus

\[
B_\nu \phi_\lambda = b_\nu(\lambda) \phi_\lambda.
\]

The symbol \( b_\nu \) is explicitly calculated in [32].

3.2. The generalized Segal-Bargmann transform. We assume in this section that \( \nu > (r-1)\frac{\nu}{2} \). The operator \( RR^* \) is well defined and by definition positive. We can therefore define \( \sqrt{RR^*} \). Then there exists a partial isometry \( U_\nu \) such that \( R^* = U_\nu \sqrt{RR^*} \). To simplify notation we will often write \( U \) for \( U_\nu \). As \( R = \sqrt{RR^*} U^* \) and \( \text{Im}(R) \) is dense it follows that \( U \) is actually a unitary isomorphism.

Definition 3.4. Let \( \nu > (r-1)\frac{\nu}{2} \). The unitary isomorphism \( U_\nu : L^2(D_\nu, d\eta) \to H_\nu(D) \) is called the generalized Segal-Bargmann transform ([38]).
Let $W = N_L(a)/Z_L(a)$ be the Weyl group of $a$ corresponding to the root system $\Delta(h, a)$ and let $f \mapsto \tilde{f}$ denote the spherical Fourier transform. Then $f \mapsto \tilde{f} = \mathcal{F}(f)$ extends to an unitary isomorphism

$$\mathcal{F} : L^2(D_R, d\eta)^L \to L^2\left(a^*/W, \frac{d\lambda}{|c(\lambda)|^2}\right) \simeq L^2\left(a^*, \frac{d\lambda}{w|c(\lambda)|^2}\right)^W,$$

where

$$c(\lambda) = c_0 \prod_{j<k} \frac{\Gamma(i(\lambda_j - \lambda_k))}{\Gamma((\rho_j - \rho_k))} \frac{\Gamma(\frac{\rho_j}{2} + i(\lambda_j - \lambda_k))}{\Gamma(\frac{\rho_j}{2} + \rho_j - \rho_k)}$$

is the Harish-Chandra $c$-function, $c_0$ is a constant whose value can be evaluated by using known integral formulas (see [31] for the case of type C and D domains), and $w$ is the order of the Weyl group $W$. Combining all of this together we now get the following proposition.

**Proposition 3.5.** Suppose $\nu > (r - 1)\frac{\rho}{2}$. Then

$$\mathcal{F} \circ U^*_\nu : \mathcal{H}_\nu(D)^L \to L^2\left(a^*, \frac{1}{w|c(\lambda)|^2}d\lambda\right)^W$$

is a unitary isomorphism.

**Corollary 3.6.** Let the notation be as above. Then the following hold:

1. If $\nu > (r - 1)\frac{\rho}{2}$ then the functions

$$\mathcal{F}U^*_\nu(\psi_m), \quad m \in \Lambda$$

form an orthogonal basis for the Hilbert space $L^2(a^*/W, |c(\lambda)|^{-2}d\lambda)$.

2. If $\nu > 1 + a(r - 1)$ then the functions

$$\sqrt{\frac{d_m(\nu)}{(\frac{\rho}{2})_m}} \mathcal{F}U^*_\nu(\psi_m), \quad m \in \Lambda$$

form an orthonormal basis for the Hilbert space $L^2(a^*/W, |c(\lambda)|^{-2}d\lambda)$.

**Proof.** This follows Lemma 2.11, part 6, and Corollary 2.14. \qed

Our first main goal of this paper is to identify the functions $\mathcal{F}U^*_\nu \psi_m$ and study their analytical properties.

4. **GENERATING FUNCTIONS AND ORTHOGONALITY RELATIONS FOR THE BRANCHING COEFFICIENTS**

In this section we derive the orthogonality relations for the branching coefficients. These results follow somewhat easily from a general consideration ([31]). In the case where one considers the branching rules for the tensor product $\mathcal{H}_\nu(D) \otimes \mathcal{H}_\nu(D)$ of $\tilde{G}$, considered as the restriction of the representation of $\tilde{G} \times \tilde{G}$ on the diagonal, the branching coefficients, also called the Clebsch-Gordan coefficients, are studied in [29], [19] and [30]. The results here parallel those obtained there. Thus, we will be brief.

Define $p_m \in \mathcal{P}(a^*)$ by the Rodrigue’s type formula

$$p_{\nu,m}(\lambda) = p_m(\lambda) := \|\psi_m\|_{L^2(V)}^{-2} \psi_m(\partial_x)(\Delta(e - x^2)^{-\nu/2}\phi_\lambda(x))|_{x=0}.$$

We can consider the polynomials $p_m(\lambda)$ as a generalization of the Hermite polynomials ([31]).

**Lemma 4.1.** Consider the expansion of $h(x)^{-\nu/2}\phi_\lambda(x) = \Delta(e - x^2)^{-\nu/2}\phi_\lambda(x)$ in terms of the $L$-invariant polynomials $\psi_m$. Then

$$\Delta(e - x^2)^{-\nu/2}\phi_\lambda(x) = \sum_{m \in \Lambda} p_{\nu,m}(\lambda)\psi_m(x)$$
Proof. Define \( P_m(\lambda) \) by
\[
\Delta(e - x^2)^{-\nu/2} \phi_\lambda(x) = \sum_{m \in A} P_m(\lambda) \psi_m(x).
\]
Differentiating both sides with respect to \( \psi_m(\partial_x) \) and setting \( x = 0 \) gives
\[
\|\psi_m\|_{F(\nu)}^2 P_m(\lambda) = P_m(\lambda) \langle \psi_m(\partial_x) \psi_m(x) \rangle|_{x=0} = P_m(\lambda) \|\psi_m\|_{F(\nu)}^2.
\]
Hence the claim.

Lemma 4.2. Assume that \( \nu > a(r - 1) \). Let \( F \in \mathcal{H}_\nu(D) \). Then
\[
\mathcal{F}(\sqrt{R \nu} R^*_\nu U^*_\nu(F))(\lambda) = c_{\nu}^{-1/2} b_{\nu}(\lambda)^{1/2} \mathcal{F}(U^*_\nu(F))(\lambda).
\]
Proof. Recall that \( RR^* = D_\nu \). Hence, for all \( f \in L^2(\mathcal{D}_\nu, d\eta)^L \),
\[
\mathcal{F}(RR^* f)(\lambda) = \mathcal{F}(D_\nu(\lambda) f)(\lambda).
\]
Furthermore,
\[
\mathcal{F}(D_\nu(\lambda) f)(\lambda) = \int D_\nu(h) \phi_\lambda(h) \, dh = c_{\nu}^{-1} B_\nu(\phi_\lambda)(1) = c_{\nu}^{-1} b_{\nu}(\lambda),
\]
since \( \phi_\lambda(1) = 1 \). Consequently,
\[
\mathcal{F}(\sqrt{R R^*} f)(\lambda) = c_{\nu}^{-1/2} \sqrt{b_{\nu}(\lambda)} \hat{f}(\lambda).
\]
Applying this to a function \( f = U^* F, F \in \mathcal{H}_\nu(D) \), gives the lemma.

The next proposition states that the polynomials \( p_m(\lambda) \) can be also obtained via the Bargman-Segal transform of \( \psi_m \).

Proposition 4.3. Assume that \( \nu > a(r - 1) \). Then
\[
\mathcal{F}(U^*_\nu \psi_m)(\lambda) = c_{\nu}^{-1/2} \sqrt{b_{\nu}(\lambda)} \|\psi_m\|_V^2 p_{\nu,m}(\lambda)
\]
Proof. Since \( \nu > a(r - 1) \), we have
\[
\int_{\mathcal{D}} h(x)^{-\nu/2} d\eta(x) < \infty.
\]
Let \( C(\rho) \) be the convex hull of \( W \cdot \rho \). By the Helgason-Johnson theorem (Theorem 8.1 of [4], p. 458, see also [10]), if \( \lambda \in \mathfrak{a}^* + iC(\rho) \) then \( \phi_\lambda \) is a bounded function on \( \mathcal{D}_\mathbb{R} \). Thus the integral defining \( B_\nu \phi_\lambda \) is absolutely convergent and
\[
B_\nu \phi_\lambda(x) = c_{\nu} \int_{\mathcal{D}_\mathbb{R}} \frac{h(x)^{\nu/2} h(y)^{\nu/2}}{h(x, y)^{\nu}} \phi_\lambda(y) \, d\eta(y) = b_{\nu}(\lambda) \phi_\lambda(x).
\]
We divide by \( c_{\nu} h(x)^{\nu/2} \). Furthermore, extend \( \|\psi_m\|_V^{-1} \psi_m, m \in A \), to an orthonormal basis \( F_n \) of \( \mathcal{H}_\nu(D) \). Then
\[
h(z, w)^{-\nu} = \sum_n F_n(z) \overline{F_n(w)}.
\]
This gives:
\[
c_{\nu}^{-1} b_{\nu}(\lambda) h(x)^{-\nu/2} \phi_\lambda(x) = \int_{\mathcal{D}_\mathbb{R}} \sum_n h(y)^{\nu/2} F_n(y) \phi_\lambda(y) \overline{F_n(x)} \, d\eta(y).
\]
We now let \( \psi_m(\partial_x)|_{x=0} \) act on both sides. For the left-hand side we use Lemma 4.1. For the right-hand side we use the fact that \( \|\psi_m\|_V^{-1} \psi_m(\partial_x) F_n(x)|_{x=0} = \delta_{mn} \frac{\|\psi_m\|_V^2}{\|\psi_m\|_V^2} \), when \( F_m \) is one of the \( \|\psi_m\|_V^{-1} \psi_m \), and 0 otherwise. We thus get
\[
\|\psi_m\|_{F(\nu)}^2 c_{\nu}^{-1} b_{\nu}(\lambda) p_m(\lambda) = \|\psi_m\|_{F(\nu)}^2 \int_{\mathcal{D}_\mathbb{R}} h(y)^{\nu/2} \psi_m(y) \phi_\lambda(y) \, d\eta(y).
\]
That is,
\[
\mathcal{F}(R \psi_m)(\lambda) = \|\psi_m\|_{F(\nu)}^2 c_{\nu}^{-1} b_{\nu}(\lambda) p_m(\lambda)
\]
The claim follows now from Lemma 4.2 as \( R = \sqrt{RR^*U^*} \).

5. Recurrence formulas for the Branching coefficients

Propositions (3.3) and (4.3) together imply that when the measure \( b(\lambda)|c(\lambda)|^{-2}d\lambda \) is associated with \( \mathfrak{a}^*/W \) then the polynomials \( p_n(\lambda) \), \( n \in \Lambda \), are orthogonal. When reference is made to the orthogonality of these polynomials it is understood to be with respect to this measure. In this section and the next we will derive the recurrence and difference formulas for the orthogonal polynomials \( p_n(\lambda) \). In most cases, our method will be to prove our formula first for \( \lambda \) in a certain integral cone where we can easily deal with the equations. To pass to the general formula we then need the following elementary result, which can be easily proved by induction. Recall the lattice \( \Lambda \) defined in (2.13).

Lemma 5.1. Suppose \( p_1(\lambda) \) and \( p_2(\lambda) \) are two polynomials in \( \mathfrak{a}_C^* \). Let \( \mu \in \mathfrak{a}_C^* \). Suppose that \( p_1(\lambda) = p_2(\lambda) \) for all \( \lambda = n + \mu \), \( n \in \Lambda \). Then \( p_1(\lambda) = p_2(\lambda) \) for all \( \lambda \in \mathfrak{a}_C^* \).

To simplify certain arguments we assume, in this and next section, that \( \nu \) is an even positive integer. To state our result we need the binomial coefficient

\[
\binom{n}{n - \gamma_k} = (n_k + \frac{a}{2}(r - k)) \prod_{j \neq k} \frac{n_k - n_j + \frac{a}{2}(j - k)}{n_k - n_j + \frac{a}{2}(j - k)},
\]

(c.f. [12]). Note that \( \binom{n}{n - \gamma_k} \) is actually a rational function of \( n \) and can be defined on all \( \mathbb{C}^n \) with singularities on some lower dimensional hyperplanes. We let

\[
c_n(k) = \prod_{j \neq k} \frac{n_j - n_k - \frac{a}{2}(j + 1 - k)}{n_j - n_k - \frac{a}{2}(j - k)}.
\]

The following theorem is essentially proved in [20], although the holomorphic discrete series \( \pi_\nu \) is realized there in a degenerate principal series representation. We will not reproduce the same proof here. In the case of \( G = SU(1, 1) \) we have \( \psi_m(z) = z^m \). This theorem and the lemma that follows are generalizations of the simple facts that

\[
\pi_\nu \left( -\begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} \right) z^m = - (\nu + m) z^{m-1} + mz^{m-1}
\]

\[
\pi_\nu \left( -\begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix} \right) z^m = (\nu + 2m) z^m,
\]

which can be verified by a simple calculation.

Theorem 5.2. Recall that \( \xi = Ad(\gamma)(-2Z_0) \). In the bounded realization \( \mathcal{H}_\nu(\mathcal{D}) \) of the representation of \( \mathfrak{g}_C \),

\[
(5.1) \quad \pi_\nu(-\xi)\psi_n = \sum_{j=1}^r \binom{n}{n - \gamma_j} \psi_{n - \gamma_j} - \sum_{j=1}^r (\nu + n_j - \frac{a}{2}(j - 1))c_n(j)\psi_{n + \gamma_j}.
\]

Remark 5.3. As is proved in [20] one may use the above formula to derive the results of Faraut-Koranyi [6] on the norm of \( \phi_n \) in the Hilbert space \( \mathcal{H}_\nu(\mathcal{D}) \). Conversely, knowing that \( \pi_\nu(\xi)\phi_n \) is of the above form, it is possible also to find recursively the coefficients by using the results in [6], the dimension formula in [20] and the fact that \( \pi_\nu(\xi) \) is a skew-symmetric operator.

The element \( 2Z_0 = D(e, \bar{e}) \) is in the center of \( \mathfrak{t} \), and thus acts on each \( \psi_n \) by a scalar. A routine calculation gives the following lemma:

Lemma 5.4. We have

\[
(5.2) \quad \pi_\nu(-2Z_0)\psi_m = (r\nu + 2|m|)\psi_m.
\]
We can draw several important relations from these facts. Recall first from Theorem 5.6, part 5 that
\[ q_{m,\nu}(z) = \Delta(z + e)^{-\nu} \psi_m \left( (z - e)(z + e)^{-1} \right) = 2^{r\nu/2} \pi_\nu(\gamma) \psi_m(z). \]
Recall that \( \pi_\nu(\gamma) \) is well defined and that
\[ \pi_\nu(\gamma) \pi_\nu(X) = \pi_\nu(\Ad(\gamma)X) \pi_\nu(\gamma) \]
for all \( X \in \mathfrak{g}c. \) As \( \Ad(\gamma^{-1})(2Z_0) = \xi \) and \( \Ad(\gamma^{-1})(\xi) = -2Z_0, \) by Lemma 2.4, we get by applying the Cayley transform to (5.1) and (5.2):

**Lemma 5.5.** Let \( q_{m,\nu}(z) = \Delta(z + e)^{-\nu} \psi_m \left( (z - e)(z + e)^{-1} \right) \) then the following holds:
1. \( \pi_\nu(\xi) q_{m,\nu} = (r\nu + 2|m|) q_{m,\nu}. \)
2. \( \pi_\nu(-2Z_0) q_{m,\nu} = \sum_{j=1}^r \left( \frac{m+j}{m} \right) q_{m-\gamma_j,\nu} - \sum_{j=1}^r (\nu + n_j - \frac{a}{2}(j-1)) c_m(j) q_{m+\gamma_j,\nu}. \)

The following theorem gives the recursion relations for the polynomials \( p_{\nu,m}. \)

**Theorem 5.6.** The following recurrence formula holds:
\[ (2 \sum_{j=1}^r (i\lambda_j + \rho_j)) p_{\nu,m}(\lambda) = \sum_{j=1}^r \left( \frac{m+j}{m} \right) p_{\nu,m+\gamma_j}(\lambda) - (\nu + m_j - 1 - \frac{a}{2}(j-1)) c_m(j) p_{\nu,m-\gamma_j}(\lambda). \]

**Proof.** We prove the result for
\[ \lambda = -i(m + \nu - \rho), \]
where \( m \in \Lambda \) and \( \frac{a}{2} \) is viewed as \( \frac{a}{2} \sum_{j=1}^r \beta_j. \) The general result for \( \lambda \in \mathbb{C}^r = \mathfrak{a}_c^* \) follows from Lemma 5.1. As \( \Ad(\gamma)\xi = -\Ad(\gamma^{-1})\xi = 2Z_0 \) we get from Lemma 5.5:
\[ \pi_\nu(x) \pi_\nu(\gamma^{-1}) \psi_m(x) = -r\nu + 2|m| \pi_\nu(\gamma^{-1}) \psi_m(x). \]

Now simplify this expression before actually performing the differentiation:
\[ \pi_\nu(\gamma^{-1}) \psi_m(x) = 2^{r\nu/2} \psi_m \left( \frac{e + x}{e - x} \right) \Delta(e - x)^{-\nu} \]
\[ = 2^{r\nu/2} \psi_{m+\frac{a}{2}} \left( \frac{e + x}{e - x} \right) \Delta \left( \frac{e^2}{e - x} \right)^{-\frac{a}{2}} \Delta(e - x)^{-\nu} \]
\[ = 2^{r\nu/2} \psi_{m+\frac{a}{2}} \left( \frac{e + x}{e - x} \right) \Delta(e - x^2)^{-\frac{a}{2}} \]
\[ = 2^{r\nu/2} \phi_\lambda(x) \Delta(e - x^2)^{-\frac{a}{2}}. \]

Here we have used that
\[ \Delta \left( \frac{e + x}{e - x} \right)^{-\nu/2} \Delta(e - x)^{-\nu} = \Delta(e + x)^{-\nu/2} \Delta(e - x)^{-\nu} = \Delta(e - x)^{-\nu/2} \Delta(e - x)^{-\nu} = \Delta(e - x^2)^{-\nu/2}. \]

Hence
\[ \pi_\nu(\xi) \Delta(e - x^2)^{-\nu/2} \phi_\lambda(x) = -r\nu + 2|m| \Delta(e - x^2)^{-\nu/2} \phi_\lambda(x). \]

On the other hand, by Lemma 4.1:
\[ \phi_\lambda(x) \Delta(e - x^2)^{-\frac{a}{2}} = \sum_{n \in \Lambda} p_n(\lambda) \psi_n(x). \]

Thus (5.5) reads
\[ \pi_\nu(\xi) \sum_{n \in \Lambda} p_n(\lambda) \psi_n(x) = -r\nu + 2|m| \sum_{n \in \Lambda} p_n(\lambda) \psi_n(x). \]
Notice that (5.6) is the power series expansion of an analytic function and the operator \( \pi_\nu(\xi) \) is a differential operator; it commutes with the summation. We thus have, in a neighborhood of \( x = 0 \),

\[
(5.8) \quad \sum_{n \in \Lambda} p_n(\lambda)\pi_\nu(\xi)\psi_n(x) = -(r\nu + 2|m|) \sum_{n \in \Lambda} p_n(\lambda)\psi_n(x).
\]

The left hand side, in view of Theorem 5.2, is

\[
(5.9) \quad \sum_{n \in \Lambda} p_n(\lambda) \left( \sum_{j=1}^{r} \binom{n}{n-\gamma_j} \psi_{n-\gamma_j}(x) - \sum_{j=1}^{r} (\nu + n_j - \a(j - 1))c_n(j)\psi_{n+\gamma_j}(x) \right)
\]

Equating the coefficients of \( \psi_n(x) \) in (5.8) and (5.9) we get

\[
(5.9) \quad (r\nu + 2|m|)p_n(\lambda) = \sum_{j=1}^{r} \binom{n + \gamma_j}{n} p_{n+\gamma_j}(\lambda) - (\nu + n_j - 1 - \a(j - 1))c_{n-\gamma_j}(j)p_{n-\gamma_j}(\lambda).
\]

The relation (5.3) implies that \( (r\nu + 2|m|) = 2|i\lambda + \rho| = 2\sum_{j=1}^{r}(i\lambda_j + \rho_j) \). This finishes the proof. \( \square \)

**Example 5.7.** If \( D \) is the unit disk, then we can take \( D_{\mathbb{R}} \) as the unit interval \((-1,1)\) on the real line. The spherical function on the unit disk is \( \phi_\lambda(x) = (\frac{1-x^2}{1+x})^\lambda \) and the expansion (4.2) reads

\[
(5.10) \quad (1-x^2)^{-\frac{\nu}{2}} \left( \frac{1+x}{1-x} \right)^{i\lambda} = (1-x)^{-\frac{\nu}{2} - i\lambda} (1+x)^{-\frac{\nu}{2} + i\lambda} = \sum_{n=0}^\infty p_{n,\nu}(\lambda)x^n
\]

with

\[
p_{n,\nu}(\lambda) = \binom{\nu}{2} + i\lambda)_n2F_1(\nu); -x, -\nu/2 - i\lambda - n + 1, 1)
\]

being the Meixner-Pollaczyk polynomials, (c.f. [2]). The action of \( \xi = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} \) on functions on \((-1,1)\) is

\[
\pi_\nu(\xi)f(x) = \nu xf(x) - (1-x^2)f'(x).
\]

Writing the function in equation (5.10) as \( G_{\nu,\lambda}(x) \) we have

\[
\pi_\nu(\xi)G_{\nu,\lambda} = (-2i\lambda)G_{\nu,\lambda}.
\]

This can be proved easily by a direct computation. It exemplifies equation (5.3) (Here, \( \rho = 0 \) and so \( i\lambda = m + \frac{\nu}{2} \)). It then implies the recurrence relation,

\[
(2i\lambda)p_{\nu,n}(\lambda) = (n+1)p_{\nu,n+1}(\lambda) - (\nu + n - 1)p_{\nu,n-1}(\lambda),
\]

and this coincides with Theorem 5.6.

**Remark 5.8.** While deriving the recurrence formula we have extended the action of \( g_{\mathbb{C}} \) and \( \gamma \) on \( \mathcal{H}_{\nu}(T(\Omega)) \) (or \( \mathcal{H}_{\nu}(D) \)) to the space of meromorphic functions on \( V \). Indeed the operator \( \pi_\nu(\gamma^{-1}) \) is up to a constant, c.f., Lemma 2.11 a unitary operator from \( \mathcal{H}_{\nu}(T(\Omega)) \) onto \( \mathcal{H}_{\nu}(D) \) so it is initially defined on \( \mathcal{H}_{\nu}(T(\Omega)) \). However, in our formulas the action of \( \pi_\nu(\gamma^{-1}) \) on \( \psi_{\lambda} \) for \( \lambda = m \) is viewed as the extended action since \( \psi_{\lambda} \) is not an element in \( \mathcal{H}_{\nu}(T(\Omega)) \). It suggests some interesting applications of the idea of extending holomorphic functions on a domain to meromorphic functions to a larger domain.
6. Difference formulas for the Branching coefficients

In this section we state and prove the difference equation for the polynomials \( p_{\nu,m}(\lambda) \)

**Theorem 6.1.** The polynomials \( p_{\nu,m}(\lambda) \) satisfy the following difference equation

\[
-(\nu + 2|n|)p_{\nu,n}(\lambda) = \sum_{j=1}^{r} \left( \frac{i\lambda + \rho - \frac{\nu}{2}}{i\lambda + \rho - \frac{\nu}{2} - \gamma_j} \right) p_{\nu,n}(\lambda + i\gamma_j) - \sum_{j=1}^{r} \left( \frac{\nu}{2} + i\lambda_j + \rho_j - \frac{a}{2}(j-1) \right) c_{\lambda + \rho - \frac{\nu}{2}}(j)p_{\nu,n}(\lambda - i\gamma_j).
\]

**Proof.** As in the proof of Theorem 5.1 it suffices to prove the theorem for those \( \lambda \) satisfying \( i\lambda + \rho = m + \nu/2 \). Equations (5.5) and (5.6) in the proof above combine to give

\[
2m \pi_{\nu}(\gamma^{-1})\psi_m = \sum_{n \in \Lambda} p_n(\lambda)\psi_n.
\]

Let the operator \( \pi_{\nu}(-2Z \circ) \) act on both sides. For the left-hand side we use Theorem 5.4, Lemma 2.4, and equation (6.1) applied to the case \( i(\lambda \pm i\gamma_j) + \rho = (m \mp \gamma_j) + \frac{\nu}{2} \) to obtain

\[
LHS = 2m \pi_{\nu}(-2Z \circ)\pi_{\nu}(\gamma^{-1})\psi_m
= 2m \pi_{\nu}(\gamma^{-1})\pi_{\nu}(\xi)\psi_m
= -2m \pi_{\nu}(\gamma^{-1})\left( \sum_{j=1}^{r} \left( \frac{m}{m - \gamma_j} \right) \psi_{m-\gamma_j} - \sum_{j=1}^{r} \left( \nu + m_j - \frac{a}{2}(j-1) \right) c_m(j)\psi_{m+\gamma_j} \right)
= - \sum_{n \in \Lambda} \left( \sum_{j=1}^{r} \left( \frac{m}{m - \gamma_j} \right) p_n(\lambda + i\gamma_j) - \sum_{j=1}^{r} \left( \nu + m_j - \frac{a}{2}(j-1) \right) c_m(j)p_n(\lambda - i\gamma_j) \right) \psi_n.
\]

For the right-hand side we obtain by Lemma 5.3

\[
RHS = \pi_{\nu}(-2Z \circ) \sum_{n \in \Lambda} p_n(\lambda)\psi_n
= \sum_{n \in \Lambda} (\nu + 2|n|)p_n(\lambda)\psi_n.
\]

The proof is completed by equating the coefficients, rewriting each occurrence of \( m \) in terms of \( \lambda \), and then applying Lemma 5.3. \( \square \)

**Example 6.2.** We continue the Example 5.7. The above difference relation can be proved by simple however tricky computations, which in turn reveal the advantage of using the representation theoretic method. Using the notation there, write \( G_\lambda(x) = G_{\nu,\lambda}(x) \) the generating function. Differentiating the expansion we get

\[
2x \frac{d}{dx} G_\lambda(x) = \sum_{n=0}^{\infty} 2np_{\nu,n}(\lambda)x^n
\]

On the other hand, differentiating the formula for \( G_\lambda(x) \) results in

\[
2x \frac{d}{dx} G_\lambda(x) = \left( \frac{\nu}{2} + i\lambda \right) \frac{2x}{1+x} G_{\lambda-i}(x) + \left( -\frac{\nu}{2} + i\lambda \right) \frac{2x}{1-x} G_{\lambda+i}(x).
\]

We observe that

\[
G_\lambda(x) = \frac{1-x}{1+x} G_{\lambda-i}(x) = \frac{1+x}{1-x} G_{\lambda+i}(x),
\]

which then imply that

\[
\nu G_\lambda(x) = \left( \frac{\nu}{2} + i\lambda \right) G_\lambda(x) + \left( \frac{\nu}{2} - i\lambda \right) G_{\lambda-i}(x) = \left( \frac{\nu}{2} + i\lambda \right) \frac{1-x}{1+x} G_{\lambda-i}(x) + \left( \frac{\nu}{2} - i\lambda \right) \frac{1+x}{1-x} G_{\lambda-i}(x)
\]

Summing the equations (6.3) and (6.4) gives

\[
(2x \frac{d}{dx} + \nu) G_\lambda(x) = \left( \frac{\nu}{2} + i\lambda \right) G_{\lambda-i}(x) + \left( \frac{\nu}{2} - i\lambda \right) G_{\lambda+i}(x)
\]

\[
(2x \frac{d}{dx} + \nu) G_{\lambda-i}(x) = \left( \frac{\nu}{2} + i\lambda \right) G_{\lambda}(x) + \left( \frac{\nu}{2} - i\lambda \right) G_{\lambda+i}(x)
\]

\[
(2x \frac{d}{dx} + \nu) G_{\lambda+i}(x) = \left( \frac{\nu}{2} + i\lambda \right) G_{\lambda-i}(x) + \left( \frac{\nu}{2} - i\lambda \right) G_{\lambda}(x)
\]
and consequently
\[(2n + \nu)p_{\nu,n}(\lambda) = \left(\frac{\nu}{2} + i\lambda\right)p_{\nu,n}(\lambda - i) + \left(\frac{\nu}{2} - i\lambda\right)p_{\nu,n}(\lambda + i)\]
or
\[-(2n + \nu)p_{\nu,n}(\lambda) = \left(-\frac{\nu}{2} + i\lambda\right)p_{\nu,n}(\lambda + i) - \left(\frac{\nu}{2} + i\lambda\right)p_{\nu,n}(\lambda - i)\]
which coincides with Theorem 6.1. The proof of Theorem 6.1 is thus conceptually clearer.

7. The restriction Principle in the unbounded realization

In this section we discuss the application of the restriction principle to the unbounded realization of $G/K$. In particular, we use this to introduce the Laguerre functions of the cone $\Omega$ and derive some relations they satisfy. For a function $F$ defined on the Siegel domain $T(\Omega) = \Omega + iJ$ let
\[R_{\nu}F(x) = RF(x) = F(x),\]
where $x \in \Omega$. Since the functions in $\mathcal{H}_{\nu}^2(T(\Omega))$ are holomorphic it follows as before that $R_{\nu}$ is injective on $\mathcal{H}_{\nu}^2(T(\Omega))$. For $y \in \Omega$, let $k_y(z) = K_{\nu}(z,y) = K(z,y)$, where $z \in T(\Omega)$. Then $k_y \in \mathcal{H}_{\nu}(T(\Omega))$ and
\[Rk_y(x) = \Gamma_\Omega(\nu) \Delta(x + y)^{-\nu}.\]

Lemma 7.1. The linear span of \(\{k_y \mid y \in \Omega\}\) is dense in $\mathcal{H}_{\nu}(T(\Omega))$.

Proof. Assume that $f \in \mathcal{H}_{\nu}(T(\Omega))$ is perpendicular to all $k_y$, $y \in \Omega$. Then $f(y) = 0$, for all $y \in \Omega$. As $f$ is holomorphic it follows that $f = 0$. \(\square\)

Recall the Beta-function for $\Omega$:
\[B_\Omega(\nu, \mu) = \int_\Omega \Delta(x + e)^{-\nu-\mu} \Delta(x)^{-d/r} \, dx,\]
which is finite for $\nu$ and $\mu$ having real parts greater than $(r - 1) \frac{a}{2}$ (\[3\], p 141).

Lemma 7.2. Let $y \in \Omega$. Then $Rk_y \in L^2_{\nu}(\Omega)$, for all $\nu > (r - 1) \frac{a}{2}$. In fact
\[\|Rk_y\| = \frac{\Gamma_\Omega(\nu)}{\Delta(y)^{\nu/2}} \sqrt{B_\Omega(\nu, \nu)}.\]

Proof. Let $y \in \Omega$. Then, performing the change of variables $x \mapsto Q(y^{\frac{1}{2}})x$ where $Q$ is the Jordan quadratic operator in the section 2.1,
\[\|Rk_y\|^2 = \frac{\Gamma_\Omega^2(\nu)}{\Delta(y)^{\nu/2}} \int_\Omega \frac{\Delta(x)^{\nu-d/r}}{\Delta(x + y)^{2\nu}} \, dx\]
\[= \frac{\Gamma_\Omega^2(\nu)}{\Delta(y)^{\nu}} \int_\Omega \frac{\Delta(x)^{\nu-d/r}}{\Delta(x + e)^{2\nu}} \, dx \quad (x \mapsto Q(y^{\frac{1}{2}})x)\]
\[= \frac{\Gamma_\Omega^2(\nu)}{\Delta(y)^{\nu}} B_\Omega(\nu, \nu) < \infty,\]
finishing the proof. \(\square\)

We need to distinguish the Laplace transform $L_\nu f$ as mapping on functions on $\Omega$ to itself and as mapping functions on $\Omega$ to holomorphic functions on $T(\Omega)$. We write the former as $L^\Omega_\nu f$, which is the restriction of the latter.

Lemma 7.3. Let $\nu > (r - 1) \frac{a}{2}$. Then the set \(\{Rk_y \mid y \in \Omega\}\) is dense in $L^2_{\nu}(\Omega)$. 
Proof. Let \( f \in L^2_\nu(\Omega) \) and suppose \( f \) is orthogonal to all \( Rk_y \), \( y \in \Omega \). Then
\[
0 = (f \mid Rk_y) = \Gamma_\Omega(\nu) \int_\Omega f(x)\Delta(x+y)^{-\nu}\Delta(x)^{\nu-d/r} \, dx
\]
\[
= \int_\Omega f(x)\mathcal{L}_\nu(e^{-(y|x)})(x)\Delta(x)^{\nu-d/r} \, dx
\]
\[
= \int_\Omega e^{-(y|x)}\mathcal{L}_\nu^\Omega(f)(x)\Delta(x)^{\nu-d/r} \, dx
\]
\[
= \mathcal{L}_\nu^\Omega(\mathcal{L}_\nu^\Omega(f))(y).
\]
From this and the injectivity of the Laplace transform it follows that \( f = 0 \).

By the previous lemmas it follows that the restriction map
\[
R : \mathcal{H}_\nu(T(\Omega)) \to L^2_\nu(\Omega)
\]
is injective, densely defined and has dense range. Since convergence in \( \mathcal{H}_\nu(T(\Omega)) \) implies uniform convergence on compact sets it follows easily that \( R \) is closed. We can thus polarize \( R^* \), \( R^* = U|R^*| \), and obtain a unitary map \( U \) from \( L^2_\nu(\Omega) \) onto \( \mathcal{H}_\nu(T(\Omega)) \). We now prove that \( U = \mathcal{L}_\nu \).

**Theorem 7.4.** Suppose \( \nu > \frac{d}{2}(r-1) \). The polar decomposition of \( R^* \) is given by \( R^* = \mathcal{L}_\nu \mathcal{L}_\nu^\Omega \), where the operator \( \mathcal{L}_\nu \) extends to a unitary operator from \( L^2_\nu(\Omega) \) onto \( \mathcal{H}_\nu^\Omega(T_\nu) \).

**Proof.** Denote temporarily \( \mathcal{L}^\Omega = \mathcal{L}_\nu^\Omega \). We define \( \mathcal{L}^\Omega \) on the domain
\[
\{ f \in L^2_\nu(\Omega) : \int_\Omega e^{-(y|x)}f(x)d\mu_\nu(x) \in L^2_\nu(\Omega) \}.
\]
Note that by Cauchy-Schwarz inequality the condition \( f \in L^2_\nu(\Omega) \) implies that \( \mathcal{L}^\Omega f \) is a well-defined function on \( \Omega \) since \( e^{-(y|x)} \) for fixed \( y \in \Omega \) is a function in \( L^2_\nu(\Omega) \). It is then easy to prove that \( \mathcal{L}^\Omega \) so defined is a self-adjoint positive operator. Let \( f \in L^2_\nu(\Omega) \) be in the domain of \( RR^* \), then
\[
RR^*f(y) = R^*f(y)
\]
\[
= (R^*f \mid k_y)_{\mathcal{H}_\nu(T(\Omega))}
\]
\[
= (f \mid Rk_y)_{L^2_\nu(\Omega)}
\]
\[
= \int_\Omega f(x)\mathcal{K}(x,y) \, d\mu_\nu(x)
\]
\[
= \Gamma_\Omega(\nu) \int_\Omega f(x)\Delta(x+y)^{-\nu} \, d\mu_\nu(x)
\]
\[
= \int_\Omega f(x)\mathcal{L}^\Omega(e^{-(y|x)})(x) \, d\mu_\nu(x)
\]
\[
= \int_\Omega e^{-(y|x)}\Delta(x)^{\nu-d/r} \mathcal{L}^\Omega(f)(x) \, dx
\]
\[
= \mathcal{L}^\Omega(\mathcal{L}^\Omega f)(y),
\]
and
\[
(\mathcal{L}^\Omega f, \mathcal{L}^\Omega f) = (R^*f, R^*f) < \infty.
\]
Thus \( f \) is in the domain of \( (\mathcal{L}^\Omega)^2 \) and \( RR^* = (\mathcal{L}^\Omega)^2 \), since \( (\mathcal{L}^\Omega)^2 \) is a self-adjoint extension of \( RR^* \), which is also self-adjoint by the von Neumann theorem (see e.g. [21], VIII. problem 45.)

Consider the inverse operator \( R^{-1} \) acting on the image of \( R \). For a function \( g \) in the image of \( R \), \( R^{-1}g \) is the unique extension of \( g \) to a holomorphic function on \( T(\Omega) \). Thus \( R^{-1} \mathcal{L}^\Omega = \mathcal{L}_\nu \). Let \( R^{-1} \) act on the previous equality (7.1)
\[
R^*f = \mathcal{L}_\nu \mathcal{L}^\Omega f.
\]
This proves the polar decomposition formula. Since \( R^* \) is densely defined and \( R \) is an injective closed operator we have that the unitary part \( \mathcal{L}_\nu \) extends to a unitary operator.
Assume that Corollary 7.6. That these isomorphisms intertwine the corresponding restriction maps. It follows then from Theorem 3.3 that R is a continuous operator for ν > a(r − 1).

**Corollary 7.6.** Assume that ν > 1 + a(r − 1). Then \( \mathcal{L}_ν^* : \mathcal{H}_ν^2(T(Ω)) \rightarrow L^2_ν(Ω) \) is given by the integral operator

\[
\mathcal{L}_ν^* F(x) = \alpha_ν \int_{T(Ω)} F(z)e^{-\langle z, x \rangle} Δ(y)^{−\nu−2d/r} \, dx \, dy
\]

where \( \alpha_ν = \frac{2^\nu}{(2\pi)^{d/r}(ν−d/r)} \).

**Proof.** Write \( \mathcal{L} \) for \( \mathcal{L}_ν \). Let \( F ∈ \mathcal{H}_ν^2(T(Ω)) \) and \( f ∈ L^2_ν(Ω) \). Then

\[
(\mathcal{L}^* F | f) = (F | \mathcal{L} f)_{\mathcal{H}_ν^2(T(Ω))}
\]

\[
= \alpha_ν \int_{T(Ω)} F(z) \bar{f}(z) Δ(y)^{−\nu−2d/r} \, dx \, dy
\]

\[
= \alpha_ν \int_{T(Ω)} F(z) e^{−\langle z, f \rangle} Δ(t)^{−d/r} Δ(y)^{−\nu−2d/r} \, dt \, dx \, dy
\]

\[
= \alpha_ν \int_{T(Ω)} \int_{T(Ω)} F(z) e^{−\langle z, f \rangle} Δ(y)^{−\nu−2d/r} \, dy \, \bar{f}(t) \, dµ_ν(t).
\]

\( \square \)

Using the Laplace transform we transfer the \( G^γ \)-action, \( π_ν \), on \( \mathcal{H}_ν^2(T(Ω)) \) to an equivalent action, denoted by \( λ_ν \), on \( L^2_ν(Ω) \) and notice the following simple fact:

**Lemma 7.7.** The \( H^ν \)-action on \( L^2_ν(Ω) \) is given by the formula

\[
λ_ν(h)f(x) = Det(h) \bar{f}(h^t x),
\]

where the determinant is taken as a real linear transformation on \( J \) and \( h^t \) denotes the transpose with respect to the real form \( (x, y) \).

**Proof.** For \( h ∈ H^ν \) a straightforward calculation gives that \( J(h, z) = Det(h) \) and \( dµ_ν(hx) = Det(h) \bar{h} dµ_ν(x) \). Thus, for \( f ∈ L^2_ν(Ω) \) we have

\[
π_ν(h)\mathcal{L}_ν f(z) = J(h^{-1}, z) \frac{\bar{h}}{h} \int_{Ω} e^{−(h^{-1}z)x} f(x) dµ_ν(x)
\]

\[
= Det(h) \frac{\bar{h}}{h} \int_{Ω} e^{−(z)x} f(h^t x) dµ_ν(h^t x)
\]

\[
= Det(h) \bar{h} \mathcal{L}_ν(f \circ h^t)(z).
\]

This calculation now implies the lemma. \( \square \)

We follow [3], p. 343, and define the generalized Laguerre polynomials by the formula

\[
L^ν_m(x) = (ν)_m \sum_{|n| ≤ |m|} \binom{m}{n} \frac{1}{|ν|_n} \psi_n(−x),
\]

and the generalized Laguerre functions by

\[
ℓ^ν_m(x) = e^{−Tr(x)} L^ν_m(2x).
\]

By Proposition XV.4.2 in [3], p. 344, we get:

**Theorem 7.8.** The Laguerre functions form an orthogonal basis of \( L^2_ν(Ω)^L \). Furthermore,

\[
\mathcal{L}_ν(ℓ^ν_m) = Γ(\mathfrak{m} + ν)q^ν_m.
\]
Let $E$ be the Euler operator on $\Omega$ (or $V$). Specifically,

$$E f(x) = \frac{d}{dt} f(tx)|_{t=1} = \frac{d}{dt} f(\exp(tZ_0) \cdot x)|_{t=0}.$$ 

We now obtain the following recursion formula.

**Theorem 7.9.** The Laguerre functions are related by the following recursion relations

$$2E \ell^\nu_m = -\nu^2 \ell^\nu_m - \sum_{j=1}^r \left( \begin{array}{c} m \\ m - \gamma_j \end{array} \right) (m_j - 1 + \nu - (j - 1) \frac{d}{2} \ell^{\nu}_{m-\gamma_j} + \sum_{j=1}^r c_m(j) \ell^\nu_{m+\gamma_j}.$$

**Proof.** By Lemma 7.7 the $H^\gamma$-action is given by

$$\lambda_\nu(h) f(x) = \det(h) \frac{d^\nu}{dx^\nu} f(h^t x),$$

The infinitesimal action is then given in the usual way by differentiation. Thus by Lemma 7.2 $Z_0 \in \mathfrak{h}^\gamma$ and $Z_0$ acts on the smooth vectors in $L^0_\mathfrak{c}(\Omega)$ by:

$$\lambda_\nu(Z_0) f(x) = (\frac{\nu^2}{2} + E) f(x).$$

According to Lemma 5.3, part 2, we have

$$-\pi_\nu(2Z_0) q_{m, \nu} = \sum_{j=1}^r \left( \begin{array}{c} m \\ m - \gamma_j \end{array} \right) q_{m-\gamma_j, \nu} - \sum_{j=1}^r (\nu + m_j - \frac{d}{2} (j - 1) c_m(j)) q_{m+\gamma_j, \nu}.$$

The inverse Laplace transform of the above equation gives

$$-2(\frac{\nu^2}{2} + E) \ell^\nu_m = \sum_{j=1}^r \left( \begin{array}{c} m \\ m - \gamma_j \end{array} \right) \frac{\ell^\nu_{m-\gamma_j}}{\Gamma(\nu + m - \gamma_j)}$$

$$- \sum_{j=1}^r (\nu + m_j - \frac{d}{2} (j - 1) c_m(j)) \frac{\ell^\nu_{m+\gamma_j}}{\Gamma(\nu + m + \gamma_j)}.$$

This simplifies to

$$-2(\frac{\nu^2}{2} + E) \ell^\nu_m = \sum_{j=1}^r \left( \begin{array}{c} m \\ m - \gamma_j \end{array} \right) \left( m_j - 1 + \nu - (j - 1) \frac{d}{2} \ell^{\nu}_{m-\gamma_j} + \sum_{j=1}^r c_m(j) \ell^\nu_{m+\gamma_j},

and proves the theorem. \qed

In the above Theorem we used the action of $Z_0$, but to directly derive a differential equation satisfied by the Laguerre functions one uses the element $\xi$ and part 1 in Lemma 5.3.

**Remark 7.10.** If the Laguerre polynomials were defined by the formula

$$\ell^\nu_m(x) = \frac{(\nu)_m}{\Gamma(\nu + m)} \sum_{|n| \leq m} \left( \begin{array}{c} m \\ n \end{array} \right) \frac{1}{(\nu)_n} \psi_n(-x) = \frac{L^\nu_m(x)}{\Gamma(\nu + m)}.$$

it would agree with our definition given in [3]. With this definition the formula in the proceeding theorem would become

$$2E \ell^\nu_m = -\nu^2 \ell^\nu_m - \sum_{j=1}^r \left( \begin{array}{c} m \\ m - \gamma_j \end{array} \right) \ell^\nu_{m-\gamma_j} + \sum_{j=1}^r (\nu + m_j - (j - 1) \frac{d}{2} c_m(j)) \ell^\nu_{m+\gamma_j},$$

**Remark 7.11.** Theorem 7.9 involves both a creation and an annihilation operator, i.e., it involves both a step up $n \mapsto n + \gamma_j$ and a step down $n \mapsto n - \gamma_j$. This is related to the fact that the element $Z_0 \in \mathfrak{g}(\mathfrak{h})$ which is used to derive the relation in Theorem 7.9 has a decomposition $\xi = E_+ + E_-$ into $H^\gamma$ invariant element where $E_+$ is in the $p^{\gamma^+}$ and steps down and $E_-$ is in $p^{\gamma^-}$ and steps up. The elements $E_+$ and $E_-$ are not in $\mathfrak{h}^\gamma_\mathfrak{c}$ and hence they act as a second order differential operator. In
the case of the upper half-plane (in particular, see Proposition 2.7 and Theorem 3.4 in [6] where we are using \( \mathbb{R} + i\mathbb{R}^+ \) as a realization of the tube domain) this corresponds to
\[
\begin{pmatrix}
0 & 1 \\
1 & 0
\end{pmatrix}
= \frac{1}{2} \begin{pmatrix}
-i & 1 \\
1 & i
\end{pmatrix} + \frac{1}{2} \begin{pmatrix}
i & 1 \\
1 & -1
\end{pmatrix}
\]
and
\[
\begin{pmatrix}
-i & 1 \\
1 & i
\end{pmatrix}
\leftrightarrow -i \frac{1}{2} \left(tD^2 + (2t + \nu)D + (t + \nu)\right)
\]
\[
\begin{pmatrix}
i & 1 \\
1 & -1
\end{pmatrix}
\leftrightarrow i \frac{1}{2} \left(tD^2 - (2t - \nu)D + (t - \nu)\right).
\]
on \(i\mathbb{R}^+\). Furthermore, one can in a similar way get a differential equation satisfied by the Laguerre functions by applying the Cayley transform to part 1 in Lemma 5.5
\[
\pi_\nu(\xi)p_{m,\nu} = (\nu + 2 |m|)p_{m,\nu}.
\]
This equation is also a second order differential equation, which in the case of the upper half-plane is
\[
(tD^2 + \nu D - t)\ell^\nu_m = -(\nu + 2n)\ell^\nu_m.
\]
All of these equations can be carried over to the general case to find the radial part of the corresponding operators. We think that it is an interesting problem to find an explicit formula for the raising operator, annihilator operator and the operator \(\pi_\nu(\xi)\), in the general case.
