1. Materials and Techniques

Materials

Reagents used in catalytic tests, such as 1-octene, allyl glycidyl ether, octafluoropentyl ether, 1,1,1,3,5,5,5-heptamethyltrisiloxane (HMTS), triethyilsilane, triethoxysilane (TriEOS) and n-decan were supplied by Sigma Aldrich and used as received. Ionic liquids: 1-butyl-3-methylimidazolium chloride, 1-butyl-4-methylpyridinium chloride, tributyltetradecylyphosphonium chloride, triethylsulphonium bis[(trifluoromethanesulfonyl)amide], trimethylsulphonium methylsulfate and lithium bis[(trifluoromethanesulfonyl)amide], dimethyl sulfate and lithium bis[(trifluoromethylsulfonyl)-imide were purchased from lolitec. The reagents used to obtain the supports and their modification, i.e. isopropanol, methanol, dioxane, ammonia solution (25%), tetraethoxy silane, titanium (IV) isopropoxide (TIPP), Kraft lignin, 1,4-dioxane, sodium(meta)periodate, 3-(trimethoxysilyl)propyl isocyanate were purchased from Sigma Aldrich and did not require additional purification. The solvents used to prepare the SILP, such as: acetonitrile and dichloromethane were purchased from Fisher Chemicals.

Techniques

The reaction yield was determined by using Clarus 680 gas chromatograph (Perkin Elmer) equipped with a 30 m capillary column Agilent VF-5ms and TCD detector. The measurement were carried out by using temperature program: 60 °C (3 min.), 10°C min⁻¹, 290°C (5 min.). Obtained hydrosilylation reaction product and synthesized ionic liquids were subjected to NMR analysis. NMR spectra were made with Bruker BioSpin (400Hz) spectrometer using acetonitrile-d₃ and chloroform-d as solvents. Ion chromatography experiments were carried out using Metrohm Eco IC system (Metrohm, Herisau, Switzerland) equipped with 863 Compact IC Autosampler, 10.0 µl injection loop and conductometric detector (maintained at room temperature). Self-regenerating Suppressor Module (MSM) (Metrohm, Herisau, Switzerland), regenerated with distilled water and sulfuric acid, was used to separate and determine anions in ionic liquids. FT-IR in situ tests were implemented by using Mettler Toledo ReactIR 15 instrument. During the experiment spectra with 256 scans for 1 at 30 second interval with resolution of 1 cm⁻¹ were recorded. The course of the reaction was determined on the basis of the disappearance of the band at 903 cm⁻¹, corresponding to the Si-H bond. The IR spectra were recorded in the Bruker Tensor 27 apparatus in the range 500–4000 cm⁻¹ of wave number. XRD analysis of inorganic supports was performed by using X-ray diffractometer Bruker D8 Advance and standard measuring cuvette. The measurement was carried out for 1 hour, at an 2theta angle length 0 – 75. Catalyst leaching from the SILP materials was tested by using ICP-MS method, carried out on Perkin Elmer Nexion 300D inductively coupled mass plasma spectrometer. Thermogravimetric analysis was performed by TA Instruments analyser, model TG Q50a at a linear heating rate 10°C/min. under nitrogen (50ml/min.). For supports samples the analysis was conducted at 1000°C, samples of ionic liquids and SILP materials were analyzed at 600°C. Surface area and porosity characteristic was performed by using Micromeritics ASAP 2010 sorptometer. The analysed samples were first degassed at 393K for 20h. The BET (Brunauer-Emmett-Teller) surface area of supports and SILP materials were determined by N2 adsorption at 77K. The total pore volumes and average pore diameters were determined by applying the Barrett–Joyner–Halenda (BJH) method to the isotherm desorption branch. Indication of the percentage of N, C, H, S in the samples was performed by elemental analysis. For this purpose Elementar Analyser Vario EL III was used. The samples were burned at a temperature of 1200°C, and then the generated gases were separated on adsorption columns and detected by the difference in thermal conductivity. SEM-EDX technique enabled to confirm presence of Mg, Si, O, S, P and C in the analysed samples, for supports and for SILP materials. For this analysis scanning electron microscope (SEM) Hitachi S-3500 N equipped with an energy-dispersive X-ray (EDX) detector Ultra Dry Silicon Drift X-ray Detector made by Thermo Scientific was used. The particle size measurement analysis was performed using the Zetasizer Nano ZS analyser by Malvern Instruments Ltd. The device analyses particles in the range of 0.6 - 6000 nm using the backscatter intensity beam of light. The analysed samples were powder dispersion in isopropanol or water, which was additionally destabilized in an ultrasonic bath.
2. Synthesis of ionic liquids

Synthesis of ionic liquids with Ntf₂

Synthesis of ionic liquids with bis(trifluoromethanesulfonyl)amide anion was carried out by metathesis reaction based on a procedure described in the literature. For this purpose 1 equivalent of corresponding chloride (1-butyl-3-methylimidazolium chloride, 1-butyl-4-methylpyridinium chloride or tributhyltetradeclrophosphonium chloride) was dissolved in 20 ml of distilled water and placed into separating funnel. Then 20 ml of dichloromethane and 1.02 equivalent of 80% aqueous solution of lithium bis(trifluoromethanesulfonyle)amide (LiNtf₂) were added. The content of the separating funnel was shaken vigorously for about 10 minutes. Then the water layer was removed and the organic layer was washed twice with distilled water and once with water and small amount of (0.02 eq) aqueous solution of LiNtf₂. The whole procedure was repeated until Cl⁻ anions in the aqueous layer disappeared. The presence or absence of chloride anions was confirmed by the test with AgNO₃. The received organic phase was transferred to a rotary evaporator to remove the solvent, and then dried under vacuum to obtain a pure ionic liquid with the Ntf₂ anion. The complete exchange of Cl⁻ to Ntf₂ anions was confirmed by ion chromatography (ESI). The structure of the obtained ionic liquids was confirmed by IR spectra and NMR analysis.

1-butyl-3-methylimidazolium bis(trifluoromethanesulfonyl)amide [BMIM][Ntf₂]

\[ \text{[BMIM][Ntf₂]} \]

1H NMR (CDCl₃) δ (ppm): 0.97 (t, J=7.4 Hz, 3H, -CH₂); 1.37 (m, 2H, -C-C-CH₂); 1.87 (m, 2H, -C-CH₂-C); 3.95 (s, 3H, N-CH₃); 4.17 (t, J=7.5 Hz, 2H, N-CH₂-); 7.28 (m, 1H, -HC-N-); 7.32 (m, 1H, -C=C-), 8.70 (s, 1H, N=CH-N)

Synthesis of ionic liquids with MeSO₄⁻

To the round flask the solution of ionic liquid (1 eq.) in 10 cm³ of acetonitrile (1-butyl-3-methylimidazolium chloride or tributhyltetradeclrophosphonium chloride) or 10 cm³ of dichloromethane (1-butyl-4-methylpyridinium chloride) was placed and stirred. Then dimethyl sulfate (1 eq.) was dispersed dropwise for 5 minutes. After dosing the entire portion of methylsulfate precursor, the flask content was stirred for additional 30 minutes. Then the solvent was evaporated and obtained ionic liquid with MeSO₄⁻ anion was dried under vacuum. The complete exchange of Cl⁻ to MeSO₄⁻ anion was confirmed by the test with AgNO₃, where formation of AgCl wasn’t observed. The structure of the obtained ionic liquids was confirmed by IR spectra and NMR analysis.

1-butyl-3-methylimidazolium methyl sulfate [BMIM][MeSO₄]

1H NMR (CDCl₃) δ (ppm): 0.95 (t, J=7.4 Hz, 3H, CH₂-C-C-); 1.35 (m, 2H, -CH₂-C-); 1.86 (m, 2H, -C-CH₂-); 3.71 (s, 3H, H₂C-O-); 3.97 (s, 3H, -CH₃); 4.21 (t, J=7.4 Hz, 2H, -H₂C-N-); 7.42 (s, 1H, -C-C-); 7.48 (s, 1H, -N=C-); 9.41 (s, 1H, -N=C-)

4. Synthesis of inorganic support

**Synthesis of titanium dioxide – silica support (TiO$_2$–SiO$_2$)**

The synthesis of the inorganic oxide system TiO$_2$–SiO$_2$ was carried out by the sol-gel method$^3$. The reaction was carried out in a 2 L three-necked round bottom flask with mechanical stirrer, at room temperature. In the first stage, 6.55 mol of propan-2-ol and 0.125 mol of titanium (IV) isopropoxide (TIPP), as a precursor of TiO$_2$, were introduced into the flask. Then 0.375 mol tetraethoxysilane (TEOS) as an organic precursor of SiO$_2$, was introduced into the reaction mixture, at a rate of 6 cm$^3$/min by using a peristaltic pump. The content of the flask was intensively stirred all the time. After dosed of all amount of TEOS, the reaction mixture was stirred for 10 min. Next, 1.97 mol of ammonia (25% aqueous solution), as a precursor of hydrolysis, by using peristaltic pump and with the same rate (6 cm$^3$/min) was dosed. Obtained colloidal suspension was additionally stirred for 1 h. Then resulting alcogel was dried at 105°C for 24 h, and then the impurities have been removed by washing precipitate several times with distilled water and filtration. Obtained TiO$_2$–SiO$_2$ was dried at 105°C for 6 h, calcinated at 600°C for 4 h and classified on sieves with a mesh size of 200 µm. In the presented research, in an analogous manner, the synthesis of oxide systems with different amounts of TiO$_2$ and SiO$_2$ precursors was carried out. The systems were prepared using an equimolar ratio of the individual precursors (0.25 mol TIPP and 0.25 mol TEOS) and with a significant excess of TiO$_2$ precursor (0.375 mol TIPP and 0.125 mol TEOS).
5. Synthesis of inorganic-organic support

Modification of TiO$_2$-SiO$_2$ surface

The TiO$_2$-SiO$_2$ surface was grafting by using dry method. For this purpose, a mixture of 8 ml of methanol and 2 ml of water was prepared and then used for hydrolysed 1.25 g of 3-(trimethoxysilyl)propyl isocyanate. To the round bottom flask 5 g of TiO$_2$-SiO$_2$ was added and previously prepared mixture was dosed by using peristaltic pump, with the rate 2 ml/min. The flask content was stirred all the time by magnetic stirrer. After dosing the entire modifier solution, the system was stirred for additional 60 minutes and then the suspension was filtrated and dried at 105°C for 24 h.

Synthesis of TiO$_2$-SiO$_2$/lignin material

The process of obtaining the TiO$_2$-SiO$_2$/lignin system was carried out in two stages. The first stage involved the activation of lignin. To the 250 ml three-necked flask added 67.5 ml of dioxane and 7.5 ml of distilled water. The system was stirred by using a mechanical stirrer a rate of 550 rpm. Then 1 g of lignin was added and the system was mixed for approx. 30 minutes. After that time, the solution consisting of 1.5 g of sodium periodate and 30 ml of water was dosed to the flask by using a peristaltic pump at the rate of 3 ml/min. The flask was darkened throughout the reaction to prevent light oxidation of the lignin. After the entire solution had been dispensed, the contents of the flask were stirred for another 30 minutes. Then 5 g of the previously modified support were added to the system and stirred for another hour. After this time, the dioxane was evaporated on a vacuum evaporator and the obtained precipitate was dried at 105 °C for 24 h.

6. Physicochemical characteristic of synthesized supports

6.2. Surface area and porosity characteristic

**Table S2.** Surface area and porosity characteristic of obtained SiO$_2$, TiO$_2$ and TiO$_2$-SiO$_2$ supports.

| Inorganic Support            | BET Surface Area [m$^2$/g] | Total Pore Volume [cm$^3$/g] | Average Pore Diameter [nm] |
|------------------------------|-----------------------------|------------------------------|----------------------------|
| SiO$_2$                      | 8                           | 0.02                         | 5.97                       |
| TiO$_2$                      | 3                           | 0.13                         | 13.08                      |
| TiO$_2$-SiO$_2$ (0.25:0.75)  | 328                         | 0.91                         | 10.95                      |
| TiO$_2$-SiO$_2$ (0.50:0.50)  | 193                         | 0.29                         | 5.59                       |
| TiO$_2$-SiO$_2$ (0.75:25)    | 183                         | 0.29                         | 5.21                       |

6.3. IR spectra

**Fig. S16.** IR spectra of TiO$_2$-SiO$_2$ (a) and TiO$_2$-SiO$_2$/lignin (b) supports

7. Preparation of Rh-SILP and Pt-SILP materials

New SLIP materials were prepared using physical impregnation method. For this purpose 0.2g of proper ionic liquid (with [BMIM]$^+$, [BMPy]$^+$, [P$_{4444}$]$^+$, [S$_{222}$]$^+$ or [S$_{111}$]$^+$ cation and Ntf$_2$ or MeSO$_4$ anion ) and rhodium or platinum catalyst (0.68 mg of Rh(PPh$_3$)$_3$ or 0.14 mg of Pt(cod)Cl$_2$) were placed in a flask and dissolved in 20 cm$^3$ dichlomethane or acetonitrile (for [S$_{111}$][MeSO$_4$]) . Then to obtained mixture 2 g of previously obtained inorganic support – TiO$_2$-SiO$_2$ was added and stirred for 30 minutes. The process of preparation of
Rh-SILP and Pt-SILP was conducted at room temperature. Next the flask was transferred to the rotary evaporator to removed solvent. The evaporation of dichloromethane was carried out very slowly to obtained even layer of ionic liquid. Then the obtained SILP material was dried under vacuum for 48 h at 40°C. Obtained materials included 10% (w/w) of ionic liquid and 4·10⁻¹% of rhodium or platinum. SILP systems with 15% and 20% (w/w) of ionic liquid were prepared in analogous way and only change was the amount of added ionic liquid corresponding respectively to 0.3 g and 0.4 g.

Fig. S29. IR spectra of the obtained SILP materials TS_L_4.2_Rh (a) and TS_L_4.2_Pt (b) (black) and ionic liquid [S111][MeSO4] (orange).

9. Catalytic tests

Catalytic activity of all obtained Rh-SILP and Pt-SILP materials was tested in the hydrosilylation reaction of 1-octene and 1,1,3,5,5-heptamethytrisiloxane (HMTS). For this purpose to the 2 ml reaction vessel 0.1 g Rh or Pt-SILP material (corresponding quantities of $10^{-5}$ mol of Rh or Pt per 1 mol of Si-H) was introduced. Then 3.68 mmol of 1-octene, 3.68 mmol of HMTS and 1 mmol of n-decane (as an internal standard) was added. Then the reaction mixture was heated to 100°C for 30 minutes, without stirring. After that time the reaction mixture was left for 10 minutes for better sedimentation process of the SILP particles. Then the reaction mixture was gently removed from the reaction vessel by a needle and syringe. The reaction mixture was then cooled and analysed by Gas Chromatograph. In the next catalytic cycle new portion of substrates was added to the catalytic material remaining in the reactor, without any regeneration. This activity was repeated until basis of GC analysis, the catalytic activity of the tested SILP material had disappeared. For the most active SILP materials hydrosilylation reactions with 1-octene, allyl-glycidyl ether, octafluorpentyl ether and HMTS, triethylsilan and triethoxysilan were additionally conducted. For reactions with ethers 4.41 mmol of olefine and 3.68 mmol of HMTS 1 mmol of n-decane was applied. The reaction conditions were analogous to the above. Obtained product was subjected to NMR or GC-MS analysis.

9.1. Results of catalytic tests with different amount of IL

Table S8. Catalytic activity of SILP materials with different amount of ionic liquid.

| Catalytic cycle No | TS_3.1_Rh_10% | TS_3.1_Pt_10% | TS_3.1_Rh_15% | TS_3.1_Pt_15% | TS_3.1_Rh_20% | TS_3.1_Pt_20% |
|--------------------|---------------|---------------|---------------|---------------|---------------|---------------|
