ANTIPERFECT MORSE STRATIFICATION

NAN-KUO HO AND CHIU-CHU MELISSA LIU

Abstract. For an equivariant Morse stratification which contains a unique open stratum, we introduce the notion of equivariant antiperfection, which means the difference of the equivariant Morse series and the equivariant Poincaré series achieves the maximal possible value (instead of the minimal possible value 0 in the equivariantly perfect case). We also introduce a weaker condition of local equivariant antiperfection. We prove that the Morse stratification of the Yang-Mills functional on the space of connections on a principal \( G \)-bundle over a connected, closed, nonorientable surface \( \Sigma \) is locally equivariantly \( \mathbb{Q} \)-antiperfect when \( G = U(2), SU(2), U(3), SU(3) \); we propose that the Morse stratification is actually equivariantly \( \mathbb{Q} \)-antiperfect in these cases. Our proposal yields formulas of Poincaré series \( P^G_t(\text{Hom}(\pi_1(\Sigma), G); \mathbb{Q}) \) when \( G = U(2), SU(2), U(3), SU(3) \). Our \( U(2), SU(2) \) formulas agree with formulas proved by T. Baird, who also verified our conjectural \( U(3) \) formula.

1. Introduction

Let $f$ be a Morse function on a compact manifold $M$, so that it has finitely many isolated nondegenerate critical points. The Morse polynomial of $f$ is defined to be

$$M_t(f) = \sum_{p \in \text{Crit}(f)} t^{\lambda_p}$$

where $\text{Crit}(f)$ is the set of critical points of $f$, and $\lambda_p$ is the Morse index of $p$. The Morse polynomial of any Morse function satisfies the Morse inequalities

$$M_t(f) - P_t(M; K) = (1 + t)R_t(K)$$

where $P_t(M; K)$ is the Poincaré polynomial of $M$ relative to a coefficient field $K$, and $R_t(K)$ is a polynomial with nonnegative coefficients. A Morse function is called $K$-perfect if $R_t(K) = 0$.

In [AB], Atiyah and Bott studied Morse theory in a much more general setting: the manifold $M$ is an infinite dimensional affine space $\mathcal{A}$ of connections on a principal $G$-bundle $P$ over a Riemann surface $\Sigma$, where $G$ is a compact connected Lie group; the functional $f$ is the Yang-Mills functional $L: \mathcal{A} \to \mathbb{R}$, $A \mapsto ||F_A||_{L^2}$, which is Morse-Bott instead of Morse

1 Indeed, $L$ is not Morse-Bott in the strict sense, since its critical sets $N_\mu$ are singular in general, but the Morse index $\lambda_\mu$ of $N_\mu$ is well-defined, and

$$M_t^G(L; K) = \sum_{\lambda \in \Lambda} t^{\lambda} P_t^G(N_\mu; K) = \sum_{\lambda \in \Lambda} t^{\lambda} P_t^G(A_\mu; K)$$

where $A_\mu$ is the stable manifold of $N_\mu$.

2 Atiyah-Bott computed $P_t(BG; \mathbb{Q})$ for $G = U(n)$ in [AB, Section 2]; their computation can be generalized to any compact connected Lie group $G$ [LR, Theorem 3.3].
$P_t^G(\mathcal{A}_{ss}; \mathbb{Q})$ of the unique open stratum $\mathcal{A}_{ss} \subset \mathcal{A}$. When the obstruction class $o_2(P) \in H^2(\Sigma; \pi_1(G)) \cong \pi_1(G)$ is torsion, the absolute minimum of the Yang-Mills functional is zero, and the unique open stratum $\mathcal{A}_{ss}$ is the stable manifold of the space $\mathcal{N}_0$ of flat connections on $P$. We have

$$P_t^G(\mathcal{A}_{ss}; \mathbb{Q}) = P_t^G(\mathcal{N}_0; \mathbb{Q}) = P_t^G(\text{Hom}(\pi_1(\Sigma), G)_P; \mathbb{Q})$$

where the subscript $P$ labels the connected component corresponding to the topological type $P$ (which is classified by the obstruction class $o_2(P)$).

In [HL1, HL2], the authors generalized some aspects of [AB] to connected, closed, nonorientable surfaces. Let $\Sigma$ be a connected, closed nonorientable surface, so that it is the connected sum of $m > 0$ copies of $\mathbb{RP}^2$. Let $\pi : \tilde{\Sigma} \to \Sigma$ be the orientable double cover, so that $\tilde{\Sigma}$ is a Riemann surface of genus $m - 1$. Let $\mathcal{A}$ and $\tilde{\mathcal{A}}$ denote the spaces of connections on a principal $G$-bundle $P \to \Sigma$ and on the pull back $\pi^*P \to \tilde{\Sigma}$, respectively. Then $\mathcal{A} \to \pi^*\tilde{\mathcal{A}}$ defines an inclusion $\mathcal{A} \hookrightarrow \tilde{\mathcal{A}}$ whose image is the fixed locus of an anti-holomorphic, anti-symplectic involution $\tau$ on $\tilde{\mathcal{A}}$, and the Yang-Mills functional $L : \mathcal{A} \to \mathbb{R}$ is, by definition, the restriction of the Yang-Mills functional on $\tilde{\mathcal{A}}$ to $\mathcal{A}$. The absolute minimum of the Yang-Mills functional $L : \mathcal{A} \to \mathbb{R}$ is always zero, achieved by flat connections. The normal bundles of Morse strata of $\mathcal{A}$ defined by $L$ are real vector bundles, so a priori one can only take $K = \mathbb{Z}_2$. Together with Ramras, the authors proved that these bundles, and their associated homotopy orbit bundles, are orientable when $G = U(n)$ or $SU(n)$ [HLR], so we may use any field coefficient in this case. When $G = U(n)$ or $SU(n)$, the Morse stratification of $\mathcal{A}$ defined by $L$ is not equivariantly $\mathbb{Q}$-perfect.

In this paper, we introduce the notion of equivariant $K$-antiperfection, which means the discrepancy $R_t^G(K)$ in (1) achieves the maximal possible value (instead of the minimal possible value 0 in the perfect case). We also introduce a weaker condition of local equivariant $K$-antiperfection. We prove that the Morse stratification defined by the Yang-Mills functional on the space of connections on a principal $G$-bundle over a connected, closed, nonorientable surface $\Sigma$ is locally equivariantly $\mathbb{Q}$-antiperfect when $G = U(2), SU(2), U(3), SU(3)$; we propose that it is actually equivariantly $\mathbb{Q}$-antiperfect in these cases. (When $G = U(1)$, there is only one stratum $\mathcal{A}_{ss} = \mathcal{A}$.) Our proposal yields formulas for the following equivariant Poincaré series when $n = 2, 3$:

$$P_t^{U(n)}(\text{Hom}(\pi_1(\Sigma), U(n))_+; \mathbb{Q}), \quad P_t^{U(n)}(\text{Hom}(\pi_1(\Sigma), U(n))-; \mathbb{Q}),$$

$$P_t^{SU(n)}(\text{Hom}(\pi_1(\Sigma), SU(n)); \mathbb{Q}),$$

where $+$ and $-$ label the components corresponding to the trivial and nontrivial $U(n)$-bundles over $\Sigma$, respectively. Indeed we show that these formulas hold if and only if equivariant $\mathbb{Q}$-antiperfection holds in the rank 2 and rank 3 cases. Our rank 2 formulas (13), (14), (15) agree with formulas proved by T. Baird [B1]. During the
revision of this paper, Baird established equivariant $\mathbb{Q}$-antiperfection in the $U(3)$ case, and thus verified our conjectural $U(3)$ formula [B3].

Acknowledgments. We thank Daniel Ramras, Michael Thaddeus, and Graeme Wilkin for helpful communications. We thank Thomas Baird for pointing out a gap in the first version of this paper. The first author was partially supported by an NSC grant 97-2628-M-006-013-MY2. The second author was partially supported by the Sloan Research Fellowship.

2. Preliminaries, Definitions, and Statements of Results

2.1. Morse stratification. Let $A$ be the space of connections on a principal $U(n)$-bundle or $SU(n)$-bundle $P$ over a connected, closed, orientable or nonorientable surface $\Sigma$, and let $G = \text{Aut}(P)$ be the group of unitary gauge transformations. $A$ is an infinite dimensional affine space, equipped with a $G$-invariant Riemannian metric. The Yang-Mills functional $L : A \to \mathbb{R}$ is invariant under the action of the gauge group $G$, and defines a $G$-equivariant Morse stratification

$$A = \bigcup_{\mu \in \Lambda} A_\mu = A_{ss} \cup \bigcup_{\mu \in \Lambda'} A_\mu$$

where $A_{ss}$ is the unique open stratum. When $n = 1$, there is only one stratum: $A = A_{ss}$. From now on we will assume $n > 1$.

The index set $\Lambda$ is partially ordered such that given $I \subset \Lambda$, $A_I := \bigcup_{\lambda \in I} A_{\lambda}$ is open if $\lambda \in I$, $\mu \leq \lambda \Rightarrow \mu \in I$; this partial ordering can be refined to a total ordering [R, Section 2]. In the following discussion, we fix a total ordering on $\Lambda$ so that we have a filtration of $A$ by open subsets. Given $\mu \in \Lambda'$, let $J = \{\lambda \in \Lambda \mid \lambda \leq \mu\}$, and let $I = J - \{\mu\}$, so that $A_I \subset A_J \subset A$ are inclusions of open subsets. We have the following isomorphisms of $G$-equivariant cohomology groups:

$$H^k_G(A_J, A_I) \cong H^k_G((A_{\mu})_\epsilon, (A_{\mu})_\epsilon - A_{\mu}) \cong H^{k-\lambda_{\mu}}_G(A_{\mu})$$

where $(A_{\mu})_\epsilon$ is a $G$-equivariant tubular neighborhood of $A_{\mu}$ in $A_J$ (see [R] Section 3) for a construction of $(A_{\mu})_\epsilon$, and $\lambda_{\mu}$ is the rank of the normal bundle $N_{\mu}$ of $A_{\mu}$ in $A$. The normal bundle $N_{\mu} \to A_{\mu}$ is a $G$-equivariant complex vector bundle when $\Sigma$ is orientable, and is a $G$-equivariant orientable real vector bundle when $\Sigma$ is nonorientable [HLR] (when $\Sigma$ is the Klein bottle, we assume that $n = 2$ or 3), so the Thom isomorphism in [H] holds for any coefficient ring. We may identify the pair $((A_{\mu})_\epsilon, (A_{\mu})_\epsilon - A_{\mu})$ with $(N_{\mu}, (N_{\mu})_0)$, where $(N_{\mu})_0$ is the complement of the zero section of the vector bundle $N_{\mu} \to A_{\mu}$. We have the following commutative diagram for any coefficient ring:
Moreover, where $i^k H \to$ Given two power series $p \to G(\underline{Z})$, we define $H \to \sum 2.2. Morse inequalities. We now consider field coefficient $K$, so that the cohomology groups are vector spaces over $K$. For any $\mu \in \Lambda'$, we define

$$Z^G_k(\mu; K) = \text{Ker} \left( H^k_G(\mu; K) \cong H^{k+\lambda_\mu}(A; A; K) \to H^{k+\lambda_\mu}_G(A; K) \right)$$

so that $Z^G_k(\mu; K)$ is a subspace of $H^k_G(\mu; K)$. We have an exact sequence

$$0 \to H^{k-\lambda_\mu}_G(\mu; K)/Z^{k-\lambda_\mu}_G(\mu; K) \to H^k_G(A; A; K) \to H^k_G(A; K) \to H^k_G(\mu; K) \to Z^{k-1-\lambda_\mu}_G(\mu; K) \to 0.$$

Define a power series

$$Z^G_t(A; K) = \sum_{k=0}^{\infty} t^k \dim_K Z^k_G(A; K) \in \mathbb{Z}[t].$$

Then the exact sequence (6) implies

$$P^G_t(A; K) + (1 + t)^{\lambda_\mu - 1} Z^G_t(A; K) = P^G_t(A; K) + t^{\lambda_\mu} P^G_t(A; K).$$

Given two power series $p(t), q(t) \in \mathbb{Z}[\llbracket t \rrbracket]$, we say $p(t) \leq q(t)$ if $q(t) - p(t)$ is a power series with nonnegative coefficients. Then

$$0 \leq Z^G_t(A; K) \leq P^G_t(A; K).$$

Define

$$R^G_t(K) = \sum_{\mu \in \Lambda'} t^{\lambda_\mu - 1} Z^G_t(A; K), \quad \tilde{M}^G_t(K) = \sum_{\mu \in \Lambda'} t^{\lambda_\mu - 1} P^G_t(A; K).$$

Note that $\lambda_\mu - 1 \geq 0$ for $\mu \in \Lambda'$, so $R^G_t(K), \tilde{M}^G_t(K)$ are power series in $\mathbb{Z}[\llbracket t \rrbracket]$ with nonnegative coefficients. The following lemma follows from the definitions and (5).

**Lemma 1.**

$$0 \leq R^G_t(K) \leq \tilde{M}^G_t(K).$$

Moreover,

(i) $R^G_t(K) = 0$ if and only if $Z^G_t(A; K) = 0$ for all $\mu \in \Lambda'$;
(ii) \( R_t^G(K) = \tilde{M}_t^G(K) \) if and only if \( Z_t^G(A_\mu; K) = P_t^G(A_\mu; K) \) for all \( \mu \in \Lambda' \).

**Remark 2.** A priori the definitions \( Z_t^G(K) \) and \( R_t^G(K) \) depends on the choice of the total ordering when such total ordering is not unique, since the index set \( J = \{ \lambda \in \Lambda \mid \lambda \leq \mu \} \) depends on the total ordering. By \((11)\) below, \( R_t^G(K) \) does not depend on the choice. \( R_t^G(K) \) can be defined for more general equivariant Morse stratification which contains a unique open stratum.

Define the \( \mathcal{G} \)-equivariant Morse series of the stratification \((3)\) as follows.

**Definition 3** (Morse series). We define the \( \mathcal{G} \)-equivariant Morse series of the \( \mathcal{G} \)-equivariant stratification \((3)\) relative to the coefficient field \( K \) to be

\[
(10) \quad M_t^G(K) = \sum_{\mu \in \Lambda} t^{\lambda_\mu} P_t^G(A_\mu; K) = P_t^G(A_{ss}; K) + t\tilde{M}_t^G(K).
\]

From \((7)\) and \((9)\) we obtain the following.

**Lemma 4** (Morse inequalities).

\[
(11) \quad P_t^G(A; K) + (1 + t)R_t^G(K) = M_t^G(K) = P_t^G(A_{ss}; K) + t\tilde{M}_t^G(K)
\]

where

\[
0 \leq R_t^G(K) \leq \tilde{M}_t^G(K) = \sum_{\mu \in \Lambda'} t^{\lambda_\mu - 1} P_t(A_\mu; K).
\]

Therefore

\[
P_t^G(A; K) - \sum_{\mu \in \Lambda'} t^{\lambda_\mu} P_t^G(A_\mu; K) \leq P_t^G(A_{ss}; K) \leq P_t^G(A; K) + \sum_{\mu \in \Lambda'} t^{\lambda_\mu - 1} P_t^G(A_\mu; K).
\]

**Remark 5.** When \( \Sigma \) is orientable, Atiyah and Bott proved that \( \alpha^k \) is injective for all \( k \) and for all \( \mu \in \Lambda' \) when \( K = \mathbb{Q} \) or \( K = \mathbb{Z}_p \) (\( p \) any prime) \([AB]\). So when \( K = \mathbb{Q} \) or \( K = \mathbb{Z}_p \) (\( p \) any prime), \( R_t^G(K) = 0 \), and

\[
P_t^G(A; K) - \sum_{\mu \in \Lambda'} t^{\lambda_\mu} P_t^G(A_\mu; K) = P_t^G(A_{ss}; K).
\]

### 2.3. Perfect stratification and antiperfect stratification

In Remark \([5]\) the stratification is said to be equivariantly \( K \)-perfect. Motivated by the definition of \( K \)-perfect stratification in \([AB]\) and the extremal cases of the Morse inequalities (Lemma \([4]\)), we introduce the following definitions. Let \( \alpha^k \) and \( \alpha^k_e \) be as in Diagram \([5]\).

**Definition 6** (perfect stratification and antiperfect stratification). We say the \( \mathcal{G} \)-equivariant stratification \((3)\) is equivariantly \( K \)-perfect if

\[
\alpha^k : H^G_\bullet(A_J, A_j; K) \to H^G_\bullet(A_J; K)
\]

is injective for all \( k \) and all \( \mu \in \Lambda' \); we say \((3)\) is equivariantly \( K \)-antiperfect if \( \alpha^k = 0 \) for all \( k \) and all \( \mu \in \Lambda' \).
Remark 7. By Lemma 7 and Lemma 8 below, the definitions in Definition 6 do not depend on the choice of total ordering.

Definition 8 (locally perfect stratification and locally antiperfect stratification). We say the $G$-equivariant stratification (3) is locally equivariantly $K$-perfect if
\[ \alpha_k^k : H^k_G(N_\mu, (N_\mu)_0; K) \to H^k_G(N_\mu; K) \]
is injective for all $k$ and all $\mu \in \Lambda'$; we say (3) is locally equivariantly $K$-antiperfect if $\alpha_k^k = 0$ for all $k$ and all $\mu \in \Lambda'$.

Remark 9. Since $\text{Ker}(\alpha_k) \subseteq \text{Ker}(\alpha_k^k)$, it is immediate from Definition 6 and Definition 8 that
\[ (3) \text{ is locally equivariantly } K\text{-perfect } \Rightarrow (3) \text{ is equivariantly } K\text{-perfect}. \]
\[ (3) \text{ is equivariantly } K\text{-antiperfect } \Rightarrow (3) \text{ is locally equivariantly } K\text{-antiperfect}. \]

From Definition 6 and the discussion in Section 2.2, we have the following equivalent conditions of equivariant perfection and antiperfection.

Lemma 10 (reformulation of equivariant perfection). The following conditions are equivalent:

P1. (3) is an equivariantly $K$-perfect stratification.
P2. For any $\mu \in \Lambda'$, the long exact sequence
\[ \cdots \to H^{k-\lambda_\mu}_G(A_\mu; K) \to H^{k}_G(A_J; K) \to H^{k}_G(A_I; K) \to H^{k+1-\lambda_\mu}_G(A_\mu; K) \to \cdots \]
breaks into short exact sequences
\[ 0 \to H^{k-\lambda_\mu}_G(A_\mu; K) \to H^{k}_G(A_J; K) \to H^{k}_G(A_I; K) \to 0. \]
P3. $Z_t^G(A_\mu; K) = 0$ for all $\mu \in \Lambda'$.
P4. $R^G_t(K) = 0$.
P5. $P_t^G(A; K) = P_t^G(A_{ss}; K) + \sum_{\mu \in \Lambda'} t^{\lambda_\mu} P_t^G(A_\mu; K)$.

Lemma 11 (reformulation of equivariant antiperfection). The following conditions are equivalent:

A1. (3) is an equivariantly $K$-antiperfect stratification.
A2. For any $\mu \in \Lambda'$, the long exact sequence (12) breaks into short exact sequences
\[ 0 \to H^{k}_G(A_J; K) \to H^{k}_G(A_I; K) \to H^{k+1-\lambda_\mu}_G(A_\mu; K) \to 0. \]
A3. $Z_t^G(A_\mu; K) = P_t^G(A_\mu; K)$ for all $\mu \in \Lambda'$.
A4. $R^G_t(K) = \tilde{M}_t^G(K)$.
A5. $P_t^G(A_{ss}; K) = P_t^G(A; K) + \sum_{\mu \in \Lambda'} t^{\lambda_\mu-1} P_t^G(A_\mu; K)$. 

When $\Sigma$ is orientable, and $K = \mathbb{Q}$ or $K = \mathbb{Z}_p$ ($p$ any prime), Atiyah and Bott showed that $e_G(N_\mu)$ in the commutative Diagram (5) is not a zero divisor in $H^*_G(A_\mu; K)$, so $\alpha^k_\mu$ is injective. We may reformulate this result as follows.

**Theorem 12** (Atiyah-Bott). Let $\mathcal{A}$ be the space of connections on a principal $U(n)$-bundle or $SU(n)$-bundle over a Riemann surface. Let $K = \mathbb{Q}$ or $K = \mathbb{Z}_p$ ($p$ any prime). Then the stratification (3) is locally equivariantly $K$-perfect; therefore it is equivariantly $K$-perfect.

### 2.4. Yang-Mills theory on a closed nonorientable surface.

Let $\Sigma$ be a connected, closed, nonorientable surface. Let $\tilde{P}$ be the pull back of $P$ to the orientable double cover $\tilde{\Sigma} \to \Sigma$. Recall that a stratum $A_\mu \subset \mathcal{A}$ corresponds to reduction of the structure group of $\tilde{P} \to \tilde{\Sigma}$ (instead of $P \to \Sigma$) to a subgroup

$$U(n_1) \times \cdots \times U(n_r) \subset U(n)$$

or

$$(U(n_1) \times \cdots \times U(n_r)) \cap SU(n) \subset SU(n)$$

where $n_1 + \cdots + n_r = n$. We say $\mu$ contains a rank 1 factor if $n_j = 1$ for some $j$. In particular, when $n = 2$ or $3$, every $\mu \in \Lambda'$ contains a rank 1 factor (see Section 3).

In Section 3 we prove the following:

**Theorem 13** (vanishing of equivariant Euler class). Let $\mathcal{A}$ be the space of connections on a principal $U(n)$-bundle or $SU(n)$-bundle ($n > 1$) over a connected, closed, nonorientable surface $\Sigma$. When $\chi(\Sigma) = 0$, so that $\Sigma$ is homeomorphic to the Klein bottle, we assume in addition that $n \leq 3$. We use rational coefficient $\mathbb{Q}$.

(i) If $\Sigma = \mathbb{RP}^2$ then $e_G(N_\mu) = 0$ for all $\mu \in \Lambda'$

(ii) If $\Sigma$ is not homeomorphic to $\mathbb{RP}^2$ then $e_G(N_\mu) = 0$ if $\mu$ contains a rank 1 factor.

Therefore $\alpha^k_\mu = 0$ for all $k$ in the above two cases.

**Corollary 14.** Let $\mathcal{A}$ be the space of connections on a principal $U(n)$-bundle or $SU(n)$-bundle ($n > 1$) over a connected, closed, nonorientable surface $\Sigma$. Then the Morse stratification (3) is locally equivariant $\mathbb{Q}$-antiperfect in the following cases:

(i) $\Sigma = \mathbb{RP}^2$, $n$ any positive integer greater than 1;

(ii) $\Sigma$ is not homeomorphic to $\mathbb{RP}^2$, $n = 2$ or 3.

Although local equivariant antiperfection does not imply equivariant antiperfection, it is natural to ask if equivariant $\mathbb{Q}$-antiperfection holds in the cases listed in Corollary 14.

**Notation 15.** Given a principal bundle $P$ over a connected, closed, orientable or nonorientable surface, let $\mathcal{A}(P)$ denote the space of connections on $P$, and let
$N_0(P)$ denote the space of flat connections on $P$. Let $G(P) = \text{Aut}(P)$ and $G_0(P)$ be the gauge group and the based gauge group, respectively.

Let $\Sigma$ be a closed, connected, nonorientable surface, so that it is the connected sum of $m > 0$ copies of $\mathbb{R}P^2$. Then the topological type of a principal $U(n)$-bundle $P \to \Sigma$ is classified by $c_1(P) \in H^2(\Sigma; \mathbb{Z}) \cong \mathbb{Z}/2\mathbb{Z}$. Let $P_{\Sigma}^{n,+}$ and $P_{\Sigma}^{n,-}$ denote the trivial ($c_1 = 0$ mod 2) and nontrivial ($c_1 = 1$ mod 2) principal $U(n)$-bundle over $\Sigma$, and let $Q_{\Sigma}^n$ be a principal $SU(n)$-bundle over $\Sigma$ (which must be topologically trivial).

We have

$$\text{Hom}(\pi_1(\Sigma), U(n)) = \text{Hom}(\pi_1(\Sigma), U(n))_{+1} \cup \text{Hom}(\pi_1(\Sigma), U(n))_{-1},$$

where

$$\text{Hom}(\pi_1(\Sigma), U(n))_{+1} \cong N_0(P_{\Sigma}^{n,+})/G_0(P_{\Sigma}^{n,+}).$$

We also have

$$\text{Hom}(\pi_1(\Sigma), SU(n)) \cong N_0(Q_{\Sigma}^n)/G_0(Q_{\Sigma}^n).$$

When $m > 1$, $\text{Hom}(\pi_1(\Sigma), U(n))_{+1}$ and $\text{Hom}(\pi_1(\Sigma), U(n))_{-1}$ are the two connected components of $\text{Hom}(\pi_1(\Sigma), U(n))$, and $\text{Hom}(\pi_1(\Sigma), SU(n))$ is connected. When $m = 1$,

$$\text{Hom}(\pi_1(\mathbb{R}P^2), U(n))_{+1} = \{a \in U(n) | a^2 = I_n, \det(a) = \pm 1\}. $$

$\text{Hom}(\pi_1(\mathbb{R}P^2), U(n))_{+1} = \text{Hom}(\pi_1(\mathbb{R}P^2), SU(n))$ is disconnected for $n \geq 2$, and $\text{Hom}(\pi_1(\mathbb{R}P^2), U(n))_{-1}$ is disconnected for $n \geq 3$.

We derive the following result in Section 4.2.

**Theorem 16** (equivariant Poincaré series, rank 2 case). Let $\Sigma$ be a connected, closed, nonorientable surface, and let $\tilde{g}$ be the genus of the orientable double cover $\tilde{\Sigma}$ of $\Sigma$. Then the stratifications on $A(P_{\Sigma}^{n,+})$, $A(P_{\Sigma}^{n,-})$, and $A(Q_{\Sigma}^n)$ are equivariantly $\mathbb{Q}$-antiperfect if and only if the following hold, respectively:

(13) $P_t^{U(2)}(\text{Hom}(\pi_1(\Sigma), U(2))_{(-1)^{\tilde{g}}}; \mathbb{Q}) = \frac{(1 + t)^{\tilde{g}}}{(1 - t^2)(1 - t^4)}((1 + t^3)^{\tilde{g}} + t^{\tilde{g}}(1 + t)^{\tilde{g}})$

(14) $P_t^{SU(2)}(\text{Hom}(\pi_1(\Sigma), U(2))_{(-1)^{\tilde{g}+1}}; \mathbb{Q}) = \frac{(1 + t)^{\tilde{g}}}{(1 - t^2)(1 - t^4)}((1 + t^3)^{\tilde{g}} + t^{\tilde{g}+2}(1 + t)^{\tilde{g}})$

(15) $P_t^{SU(2)}(\text{Hom}(\pi_1(\Sigma), SU(2)); \mathbb{Q}) = \begin{cases} (1 + t^3)^{\tilde{g}} + t^{\tilde{g}}(1 + t)^{\tilde{g}}, & \text{if } \tilde{g} \text{ is even}, \\ (1 + t^3)^{\tilde{g}} + t^{\tilde{g}+2}(1 + t)^{\tilde{g}}, & \text{if } \tilde{g} \text{ is odd}. \end{cases}$

The formulas in Theorem 16 have been proved by T. Baird [31]:

**Theorem 17** (Baird). (13), (14), and (15) hold for any $\tilde{g} \geq 0$.
From Theorem 16 and Theorem 17 we conclude that

**Corollary 18.** Let \( \mathcal{A} \) be the space of connections on a principal \( U(2) \)-bundle or \( SU(2) \)-bundle over a connected, closed, nonorientable surface. Then the Morse stratification (3) on \( \mathcal{A} \) is equivariantly \( \mathbb{Q} \)-antiperfect.

We derive the following result in Section 4.3.

**Theorem 19** (equivariant Poincaré series, rank 3 case). Let \( \Sigma \) be a connected, closed, nonorientable surface, and let \( \tilde{g} \) be the genus of the orientable double cover \( \tilde{\Sigma} \) of \( \Sigma \). Then the stratifications (3) on \( \mathcal{A}(P_{\Sigma}^{3,\pm}) \) and \( \mathcal{A}(Q_{\Sigma}^{3}) \) are equivariantly \( \mathbb{Q} \)-antiperfect if and only if the following (16) and (17) hold, respectively.

\[
P^{U(3)}_{t} \left( \text{Hom}(\pi_{1}(\Sigma), U(3))_{\pm}; \mathbb{Q} \right) = P^{SU(3)}_{t} \left( \text{Hom}(\pi_{1}(\Sigma), SU(3))_{\pm}; \mathbb{Q} \right) = \frac{(1 + t)^{\tilde{g}}}{(1-t^{2})(1-t^{4})(1-t^{6})} \left( (1 + t^{3})^{\tilde{g}} + t^{3\tilde{g}} \right)
\]

\[
(16)
\]

\[
P^{SU(3)}_{t} \left( \text{Hom}(\pi_{1}(\Sigma), SU(3))_{\pm}; \mathbb{Q} \right) = \frac{(1 + t^{3})^{\tilde{g}} + t^{3\tilde{g}} \left( 1 + t^{2} + t^{4} \right)}{(1-t^{4})(1-t^{6})}
\]

**Conjecture 20.** (16) and (17) hold for any \( \tilde{g} \geq 0 \).

During the revision of this paper, T. Baird showed that the stratifications (3) on \( \mathcal{A}(P_{\Sigma}^{n,\pm}) \) and \( \mathcal{A}(P_{\Sigma}^{n}) \) are equivariantly \( \mathbb{Q} \)-antiperfect for \( n = 3 \), but not equivariantly \( \mathbb{Q} \)-antiperfect for \( n \geq 4 \) [B2]. Therefore (16) holds for any \( \tilde{g} \geq 0 \). Using a different approach, Baird verified our conjectural rank 3 formulas (16) and (17) when \( \Sigma \) is the real projective plane \((\tilde{g} = 0)\) or the Klein bottle \((\tilde{g} = 1)\) [B2].

### 3. Equivariant Euler Class

Let \( \Sigma \) be a connected, closed, nonorientable surface, so that it is the connected sum of \( m \) copies of \( \mathbb{R}P^{2} \), and let \( \pi: \tilde{\Sigma} \rightarrow \Sigma \) be the orientable double cover, so that \( \tilde{\Sigma} \) is a Riemann surface of genus \( \tilde{g} = m - 1 \). Let \( P^{n,\pm}_{\Sigma} \) and \( P^{n}_{\Sigma} \) be defined as in Section 2.3, and let \( P^{n,k}_{\Sigma} \) denote the degree \( k \) principal \( U(n) \)-bundle on \( \tilde{\Sigma} \). Then \( \pi^{*}P^{n,\pm}_{\Sigma} \cong P^{n,0}_{\Sigma} \cong U(n) \times \tilde{\Sigma} \) is a trivial \( U(n) \)-bundle over \( \tilde{\Sigma} \).

Let \( \mathcal{A}(P), \mathcal{N}_{0}(P), \mathcal{G}(P) \), and \( \mathcal{G}_{0}(P) \) be defined as in Notation 15. There is an inclusion \( \mathcal{A}(P^{n,\pm}_{\Sigma}) \hookrightarrow \mathcal{A}(P^{n,0}_{\Sigma}) \) defined by \( A \mapsto \pi^{*}A \), and the image is the fixed locus of an anti-symplectic, anti-holomorphic involution \( \tau^{\pm} \) on \( \mathcal{A}(P^{n,0}_{\Sigma}) \). The Yang-Mills functional on \( \mathcal{A}(P^{n,\pm}_{\Sigma}) \) is, by definition, restriction of the Yang-Mills functional on \( \mathcal{A}(P^{n,0}_{\Sigma}) \) to \( \mathcal{A}(P^{n,0}_{\Sigma})_{\tau^{\pm}} \). The Yang-Mills functional on \( \mathcal{A}(P^{n,0}_{\Sigma}) \) and the metric on \( \mathcal{A}(P^{n,0}_{\Sigma}) \) are invariant under the involutions \( \tau^{+}, \tau^{-} \). The Morse strata of \( \mathcal{A}(P^{n,\pm}_{\Sigma}) \) are of the form \( \mathcal{A}_{\mu} = \tilde{\mathcal{A}}_{\mu} \cap \mathcal{A}(P^{n,0}_{\Sigma})_{\tau^{\pm}} \), where \( \tilde{\mathcal{A}}_{\mu} \) is a Morse stratum of \( \mathcal{A}(P^{n,0}_{\Sigma}) \).
The Yang-Mills functional is invariant under the action of the gauge group, and each Morse stratum is preserved by the action of the gauge group. Since the arguments for \( A(P_{\Sigma}^{n, -}) \) and \( A(P_{\Sigma}^{n, +}) \) are the same, we will use the notation \( A \) instead of \( A(P_{\Sigma}^{n, \pm}) \) when there is no confusion.

### 3.1. Atiyah-Bott types

The Morse strata on \( A(P_{n, k}^{\Sigma}) \) are labeled by the Atiyah-Bott types \( \mu \in I_{n, k} \), where

\[
I_{n, k} = \left\{ \mu = (\mu_1, \ldots, \mu_n) = \left( \begin{array}{c} k_1/n_1, \ldots, k_1/n_1 \\ n_1 \\ \vdots \\ k_m/n_m, \ldots, k_m/n_m \\ n_m \end{array} \right) \right\}
\]

\( n_j \in \mathbb{Z}_{>0}, k_j \in \mathbb{Z}, \sum_{j=1}^{m} n_j = n, \sum_{j=1}^{m} k_j = k, k_1/n_1 > \cdots > k_m/n_m \}

The Morse stratification on \( A(P_{n, k}^{\Sigma}) \) is given by

\[
A(P_{n, k}^{\Sigma}) = \bigcup_{\mu \in I_{n, k}} \tilde{A}_\mu.
\]

The unique open stratum is

\[
A(P_{n, k}^{\Sigma})_{ss} = \tilde{A}_k.
\]

The partial ordering on \( I_{n, k} \) is given by

\[
\mu \geq \nu \text{ iff } \sum_{j \leq i} \mu_j \geq \sum_{j \leq i} \nu_j, \quad \forall \ i = 1, \ldots, n - 1.
\]

The involution \( \tau^\pm \) acts on strata by \( A_\mu \mapsto A_{\tau_0(\mu)} \), where

\[
\tau_0 : I_{n, 0} \to I_{n, 0}, \quad (\mu_1, \ldots, \mu_n) \mapsto (-\mu_n, \ldots, -\mu_1).
\]

Using the same notation as in [HL1, Section 7.1], denote \( I_{0} = I_{0,0}^{\tau_0} \) the fixed point set of \( \tau_0 \) on \( I_{n, 0} \). Then any \( \mu \in I_{n, 0} \) is of the form

\[
(18) \quad \mu = \left( \begin{array}{c} k_1/n_1, \ldots, k_1/n_1 \\ n_1 \\ \vdots \\ k_r/n_r, \ldots, k_r/n_r \\ n_r \end{array} \right), \quad 0, \ldots, 0, \quad -k_r/n_r, \ldots, -k_1/n_1, \ldots, -k_1/n_1
\]

where

\[
k_1/n_1 > \cdots > k_r/n_r > 0, \quad n_0 \geq 0, \quad n_i > 0, \quad 2(n_1 + \cdots + n_r) + n_0 = n.
\]

Define

\[
I_{n}^{0} = \{ \mu \in I_n \mid \mu_i = 0 \text{ for some } i \}.
\]

For \( \mu \in I_{n}^{0} \), \( \tilde{A}_\mu \) intersects both \( A(P_{\Sigma}^{n, 0})^{+} \) and \( A(P_{\Sigma}^{n, 0})^{-} \). Note that \( I_n = I_{n}^{0} \) when \( n \) is odd.

When \( n = 2n' \) is even, any \( \mu \in I_n \setminus I_{n}^{0} \) is of the form

\[
(19) \quad \mu = (\nu, \tau_0(\nu)), \quad \nu \in I_{n', k}, \quad \nu_1 > \cdots > \nu_{n'} > 0.
\]
By [HL1] Section 7.1, \( \hat{A}_\mu \) intersect \( \mathcal{A}(P_{n,0}^{n,0})^+ \) (resp. \( \mathcal{A}(P_{n,0}^{n,0})^- \)) if and only if \( n\chi(\Sigma) + k \) is even (resp. odd). Here \( \chi(\Sigma) \) is the Euler characteristic of the nonorientable surface \( \Sigma \); if \( \Sigma \) is the connected sum of \( m \) copies of \( \mathbb{R}P^2 \), then \( \chi(\Sigma) = 2 - m \).

When \( n = 2n' \) is even, we define
\[
I_n^\pm(\Sigma) = \{ (\nu, \tau_0(\nu)) \in I_n \setminus I_0^+ | \nu \in I_{n',k}, (-1)^{n'}\chi(\Sigma)+k = \pm 1 \}.
\]
When \( n \) is odd, we define \( I_n^\pm(\Sigma) \) to be empty sets. Then
\[
\mathcal{A}(P_{n,0}^{n,0})^\pm = \bigcup_{\mu \in I_n^0 \cup I_n^+} \mathcal{A}_\mu.
\]

By the discussion in [HLR] Secton 3.3], there is an inclusion \( \iota : \mathcal{A}(Q_{\Sigma}^n) \hookrightarrow \mathcal{A}(P_{\Sigma}^{n,0})^+ \), and the Morse stratification on \( \mathcal{A}(Q_{\Sigma}^n) \) is given by
\[
\mathcal{A}(Q_{\Sigma}^n) = \bigcup_{\mu \in I_n^0 \cup I_n^+} \mathcal{A}'_\mu
\]
where \( \mathcal{A}'_\mu = \mathcal{A}_\mu \cap \mathcal{A}(Q_{\Sigma}^n) \). Let
\[
\mathcal{G}' = \text{Aut}(Q_{\Sigma}^n) = \text{Map}(\Sigma, SU(n)), \quad \mathcal{G} = \text{Aut}(P_{\Sigma}^{n,0})^+ = \text{Map}(\Sigma, U(n)),
\]
and let \( N_\mu \) (resp. \( N'_\mu \)) be the normal bundle of \( \mathcal{A}_\mu \) (resp. \( \mathcal{A}'_\mu \)) in \( \mathcal{A}(P_{\Sigma}^{n,0})^+ \) (resp. \( \mathcal{A}(Q_{\Sigma}^n) \)). Then there are continuous maps
\[
(\mathcal{A}'_\mu)_{\mathcal{G}'}, \quad (\mathcal{A}_\mu)_{\mathcal{G}}, \quad q_\mu \rightarrow (\mathcal{A}_\mu)_{\mathcal{G}}
\]
and the vector bundle \( (N'_\mu)_{\mathcal{G}'} \) over \( (\mathcal{A}'_\mu)_{\mathcal{G}'} \) is the pullback of the vector bundle \( (N_\mu)_{\mathcal{G}} \) over \( (\mathcal{A}_\mu)_{\mathcal{G}} \) under \( q_\mu \circ \iota_\mu \). So if \( c_\mathcal{G}(N_\mu) = 0 \) then \( c_\mathcal{G}'(N'_\mu) = 0 \). Therefore, to prove the vanishing of the equivariant Euler class (Theorem 13), it suffices to consider the \( U(n) \) case.

### 3.2. Decomposition of the normal bundle.

Let \( E = P_{\Sigma}^{n,k} \times U \mathbb{C}^n \) be the complex vector bundle associated to the fundamental representation \( \rho : U(n) \rightarrow GL(n, \mathbb{C}) \). Then \( E \rightarrow \overline{\Sigma} \) is a rank \( n \), degree \( k \) complex vector bundle equipped with a Hermitian metric \( h \), and \( \mathcal{A}(P_{\Sigma}^{n,k}) \) can be identified with \( \mathcal{A}(E, h) \), the space of Hermitian connections on \( (E, h) \) (i.e. connections on \( E \) that are compatible with the Hermitian metric \( h \)). Let \( \mathcal{C}(E) \) denote the space of holomorphic structures on \( E \). Then there is an isomorphism \( \mathcal{A}(P_{\Sigma}^{n,k}) \cong \mathcal{C}(E) \) of complex affine spaces, given by \( \nabla \mapsto \nabla^0,1 \).

Let \( \mathcal{E} \) denote \( E \) equipped with a \((0,1)\)-connection (holomorphic structure), so that \( \mathcal{E} \) can be viewed as a point in \( \mathcal{C}(E) \) and thus a point in \( \mathcal{A}(P_{\Sigma}^{n,k}) \).

Let \( \mu \in I_n^0 \cup I_n^+ \) be as in [15], so that \( \mathcal{A}_\mu \) is a stratum of \( \mathcal{A}(P_{\Sigma}^{n,0})^\pm \), and
\[
\mathcal{A}_\mu = \hat{A}_\mu \cap \mathcal{A}(P_{\Sigma}^{n,0})^\pm
\]
where \( \hat{A}_\mu \) is the corresponding stratum of \( \mathcal{A}(P_{\Sigma}^{n,0}) \) labeled by the same Atiyah-Bott type \( \mu \). Let \( N_\mu \) be the critical set of \( \mathcal{A}_\mu \), and let \( \iota : N_\mu \hookrightarrow \mathcal{A}_\mu \) be the inclusion map.
There is a gauge equivariant deformation retraction \( r : A_\mu \to N_\mu \), so \( e_G(N_\mu) = 0 \) if and only if \( e_G(i^*N_\mu) = 0 \). We have the following equivalences of equivariant pairs:

\[
(A_\mu, \mathcal{G}(P_{\Sigma}^{n,\pm})) \sim (N_\mu, \mathcal{G}(P_{\Sigma}^{n,\pm})) \\
\sim (N_0(P_{\Sigma}^{n_0,\pm}), \mathcal{G}(P_{\Sigma}^{n_0,\pm})) \times \prod_{j=1}^{r} (N_{ss}(P_{\Sigma}^{n_{j_1},k_j}), \mathcal{G}(P_{\Sigma}^{n_{j_1},k_j})).
\]

When \( \mu \in \mathfrak{f}_n^0 \) so that \( n_0 > 0 \), the parity of \( P_{\Sigma}^{n_0,\pm} \) can either agree or disagree with that of \( P_{\Sigma}^{n,\pm} \).

A point in \( N_\mu \) corresponds to a holomorphic vector bundle \( \mathcal{E} \) of the form

\[
\mathcal{E} = D_1 \oplus \cdots \oplus D_r \oplus D_0 \oplus \tau_C(D_0) \oplus \cdots \oplus \tau_C(D_1)
\]

where \( D_j \) is a degree \( k_j \), rank \( n_j \) polystable vector bundle, \( D_0 \) is a degree 0, rank \( n_0 \) polystable vector bundle, \( \tau_C(D_0) = \tau^*D_j^* \) and \( \tau_C(D_0) \cong D_0 \) (see [HLR, Section 3] for more details).

Let \( \tilde{N}_\mu \) be the normal bundle of \( \tilde{A}_\mu \) in \( \mathcal{A}(P_{\Sigma}^{n,0}) \). Then the fiber of \( \tilde{N}_\mu \) at \( \mathcal{E} \) is

\[
(\tilde{N}_\mu)_\mathcal{E} = H^1(\tilde{\Sigma}, \text{End}''(\mathcal{E})) \\
= \bigoplus_{0 < i < j} H^1(\tilde{\Sigma}, \text{Hom}(D_i, D_j)) \oplus \bigoplus_{0 < i < j} H^1(\tilde{\Sigma}, \text{Hom}(\tau_C(D_j), \tau_C(D_i))) \\
\oplus \bigoplus_{0 < i, j} H^1(\tilde{\Sigma}, \text{Hom}(D_i, \tau_C(D_j))) \\
\oplus \bigoplus_{i > 0} H^1(\tilde{\Sigma}, \text{Hom}(D_i, D_0)) \oplus \bigoplus_{i > 0} H^1(\tilde{\Sigma}, \text{Hom}(D_0, \tau_C(D_i))).
\]

As explained in [HLR, Section 4.1], \( \tau \) induces conjugate linear maps of complex vector spaces:

\[
H^1(\tilde{\Sigma}, \text{Hom}(D_i, D_j)) \to H^1(\tilde{\Sigma}, \text{Hom}(\tau_C(D_j), \tau_C(D_i))), \text{ and its inverse,}
\]

\[
H^1(\tilde{\Sigma}, \text{Hom}(D_i, \tau_C(D_j))) \to H^1(\tilde{\Sigma}, \text{Hom}(D_j, \tau_C(D_i))),
\]

\[
H^1(\tilde{\Sigma}, \text{Hom}(D_i, D_0)) \to H^1(\tilde{\Sigma}, \text{Hom}(D_0, \tau_C(D_i))), \text{ and its inverse.}
\]

Let \( N_\mu \) be the normal bundle of \( A_\mu \) in \( \mathcal{A}(P_{\Sigma}^{n,\pm}) = \mathcal{A}(P_{\Sigma}^{n,0})^{\tau^\pm} \). Then the fiber of \( N_\mu \) at \( \mathcal{E} \) is

\[
(N_\mu)_\mathcal{E} = H^1(\tilde{\Sigma}, \text{End}''(\mathcal{E}))^\tau \\
\cong \bigoplus_{0 < i < j} H^1(\tilde{\Sigma}, \text{Hom}(D_i, D_j)) \oplus \bigoplus_{0 < i < j} H^1(\tilde{\Sigma}, \text{Hom}(D_i, \tau_C(D_j))) \\
\oplus \bigoplus_{j > 0} H^1(\tilde{\Sigma}, \text{Hom}(D_j, D_0)) \oplus \bigoplus_{j > 0} H^1(\tilde{\Sigma}, \text{Hom}(D_j, \tau_C(D_j)))^\tau
\]
Therefore $i^*N_\mu = N^C_\mu \oplus N^R_\mu$, where

$$(N^C_\mu)_\xi = \bigoplus_{0 < i < j} H^1\left(\Sigma, \text{Hom}(D_i, D_j)\right) \oplus \bigoplus_{0 < i < j} H^1\left(\Sigma, \text{Hom}(D_i, \tau_C(D_j))\right)$$

and

$$(N^R_\mu)_\xi = \bigoplus_{j > 0} H^1\left(\Sigma, \text{Hom}(D_j, \tau_C(D_j))\right).$$

Note that $N^C_\mu$ is a complex vector bundle over $N_\mu$ and $N^R_\mu$ is a real vector bundle over $N_\mu$. We have

$$(21) e_G(i^*N_\mu) = e_G(N^C_\mu) \cup e_G(N^R_\mu).$$

Let

$$\lambda_\mu = \text{rank}_R N_\mu, \quad \lambda^C_\mu = \text{rank}_C N^C_\mu, \quad \lambda^R_\mu = \text{rank}_R N^R_\mu.$$

Then

$$\lambda_\mu = 2\lambda^C_\mu + \lambda^R_\mu.$$

**Lemma 21.** Let $K = \mathbb{Q}$ or $K = \mathbb{Z}_p$ ($p$ any prime). Then $e_G(N^C_\mu)$ is not a zero divisor in $H^*_G(N_\mu; K)$.

**Proof.** Let $U(1)_j$ be the center of $U(n_j)$, the group of constant gauge transformation on $P_{\Sigma}^{n_j, k_j}$. Let $T^r = U(1)_1 \times \cdots \times U(1)_r$. Then $T^r \subset G(P_{\Sigma}^{n_0, \pm}) \times \prod_{j=1}^{r} G(P_{\Sigma}^{n_j, k_j})$ acts trivially on $N_0(P_{\Sigma}^{n_0, \pm}) \times \prod_{j=1}^{r} N_{ss}(P_{\Sigma}^{n_j, k_j})$, and the weights of the $T^r$-action on $N^C_\mu$ are given by

$$t_j t_i^{-1} \text{ on } H^1\left(\Sigma, \text{Hom}(D_i, D_j)\right), \quad i < j,$$

$$t_j t_i^{-1} \text{ on } H^1\left(\Sigma, \text{Hom}(D_i, \tau_C(D_j))\right), \quad i < j,$$

and

$$t_j^{-1} \text{ on } H^1\left(\Sigma, \text{Hom}(D_j, D_0)\right), \quad j > 0.$$

where $(t_1, \cdots, t_r) \in T^r$ (cf: [AB, p.569]). So the representation of $T^r$ on the fiber of $N^C_\mu$ is primitive. By [AB] Proposition 13.4), $e_G(N^C_\mu)$ is not a zero divisor in $H^*_G(N_\mu; K)$.

By (21) and Lemma 21, $e_G(i^*N_\mu) = 0$ if and only if $e_G(N^R_\mu) = 0$. To study $N^R_\mu$, we reduce it to bundles over representation varieties, which we recall in the next subsection.

### 3.3. Representation varieties for Yang-Mills connections

Let $\Sigma_\ell^0$ be the closed, compact, connected, orientable surface with $\ell \geq 0$ handles. Let $\Sigma_\ell^0$ be the connected sum of $\Sigma_0^0$ and $\mathbb{R}P^2$, and let $\Sigma_\ell^2$ be the connected sum of $\Sigma_0^0$ and a Klein bottle. Any connected, closed, nonorientable surface is of the form $\Sigma_\ell^i$, where $\ell$ is a nonnegative integer and $i = 1, 2$. Note that $\Sigma_\ell^i$ is the connected sum of $(2\ell + i)$-copies of $\mathbb{R}P^2$, and that the orientable double cover of $\Sigma_\ell^i$ is $\tilde{\Sigma}_\ell^0$, where $\tilde{g} = 2\ell + i - 1$. 
A Yang-Mills $G$-connection on $\Sigma$ gives rise to a homomorphism $\Gamma_{\mathbb{R}}(\Sigma) \to G$ where $\Gamma_{\mathbb{R}}(\Sigma)$ is the super central extension introduced in [HL1 Section 4.6]. Given $V = (a_1, b_1, \ldots, a_\ell, b_\ell) \in G^{2\ell}$, define

$$m(V) = \prod_{i=1}^\ell [a_i, b_i], \quad r(V) = (b_\ell, a_\ell, \ldots, b_1, a_1).$$

In [HL1], the authors introduced the following symmetric representation varieties of a point if $d$ is given by

$$Z_{YM}(U(n))_{\pi n, \ldots, \pi n} = \{(V, c, V', c', -2\sqrt{-1}\pi \frac{k}{n} I_n) \mid V, V' \in U(n)^{2\ell}, c, c' \in U(n), m(V) = e^{-\pi \sqrt{-1}k/n} I_n c c', m(V') = e^{-\pi \sqrt{-1}k/n} I_n c' c\},$$

$$Z_{YM}(U(n))_{\pi n, \ldots, \pi n} = \{(V, d, c, V', d', c', -2\sqrt{-1}\pi \frac{k}{n} I_n) \mid V, V' \in U(n)^{2\ell}, d, d', c, c' \in U(n), m(V) = e^{-\pi \sqrt{-1}k/n} I_n d d' c^{-1} d, m(V') = e^{\pi \sqrt{-1}k/n} I_n c' d c^{-1} d'\}.$$

We also have the following representation variety of Yang-Mills connections on $\Sigma_0$:

$$X_{YM}(U(n))_{\pi n, \ldots, \pi n} = \{(V, -2\sqrt{-1}\pi \frac{k}{n} I_n) \mid V \in U(n)^{2g}, m(V) = e^{-2\pi \sqrt{-1}k/n} I_n\} 
\cong \mathcal{N}_{ss}(P_{\Sigma_0}^0, \mathcal{G}_0(P_{\Sigma_0}^0)).$$

Note that $X_{YM}(U(n))_{\pi n, \ldots, \pi n}$ is empty unless $\frac{k}{n} \in \mathbb{Z}$, and $X_{YM}(U(n))_{d, \ldots, d}$ consists of a point if $d \in \mathbb{Z}$.

The surjective maps $\Phi_{\ell,i} : Z_{YM}(U(n))_{\pi n, \ldots, \pi n} \to X_{YM}(U(n))_{\pi n, \ldots, \pi n}$ are given by

$$\Phi_{\ell,1}(V, c, V', c', -2\sqrt{-1}\pi \frac{k}{n} I_n) = (V, c r(V') c^{-1}, -2\sqrt{-1}\pi \frac{k}{n} I_n)$$

$$\Phi_{\ell,2}(V, d, c, V', d', c', -2\sqrt{-1}\pi \frac{k}{n} I_n) = (V, d^{-1} c r(V') c^{-1} d, d' c c', -2\sqrt{-1}\pi \frac{k}{n} I_n)$$

In particular, when $n = 1, k \in \mathbb{Z}$, we have

$$Z_{YM}(U(1))_{k} = \{(V, c, V', (-1)^k c^{-1}, -2\sqrt{-1}\pi k) \mid V, V' \in U(1)^{2\ell}, c \in U(1)\} 
\cong U(1)^{4\ell+1},$$

$$Z_{YM}(U(1))_{k} = \{(V, d, c, V', (-1)^k d^{-1}, c', -2\sqrt{-1}\pi k) \mid V, V' \in U(1)^{2\ell}, d, c, c' \in U(1)\} 
\cong U(1)^{4\ell+3},$$

$$X_{YM}(U(1))_{k} = \{(V, -2\sqrt{-1}\pi k) \mid V \in U(1)^{2g}\} \cong U(1)^{2g}.$$

The maps $\Phi_{\ell,i} : Z_{YM}(U(1))_{k} \cong U(1)^{4\ell+2i-1} \to X_{YM}(U(1))_{k} \cong U(1)^{4\ell+2i-2}$, $i = 1, 2$, are given by

$$\Phi_{\ell,1}(V, c, V', (-1)^k c^{-1}, -2\sqrt{-1}\pi k) = (V, c r(V'), -2\sqrt{-1}\pi k)$$

$$\Phi_{\ell,2}(V, d, c, V', (-1)^k d^{-1}, c', -2\sqrt{-1}\pi k) = (V, c r(V'), d^{-1}, c c', -2\sqrt{-1}\pi k)$$

Note that $\Phi_{\ell,1}$ and $\Phi_{\ell,2}$ are well-defined because $\Phi_{\ell,1}$ and $\Phi_{\ell,2}$ are surjective.
3.4. Vanishing of equivariant Euler class. Let \( \mathbb{V}_{n_j,k_j} \to \mathcal{N}_{ss}(P_{\Sigma}^{n_j,k_j}) \) be the real vector bundle whose fiber over \( D_j \in \mathcal{N}_{ss}(P_{\Sigma}^{n_j,k_j}) \) is \( H^1(\bar{\Sigma}, \text{Hom}(D_j, \tau_G(D_j))) \). Then \( \mathbb{V}_{n_j,k_j} \) is a \( G_j \)-equivariant real vector bundle of rank \( 2n_jk_j + n_j^2(\bar{g} - 1) \), where \( G_j = G(P_{\Sigma}^{n_j,k_j}) \) and \( \bar{g} \) is the genus of \( \bar{\Sigma} \).

For \( j = 1, \ldots, r \), let
\[
\mathcal{N}_{ss}(P_{\Sigma}^{n_0, \pm}) \times \prod_{i=1}^r \mathcal{N}_{ss}(P_{\Sigma}^{n_i,k_i}) \rightarrow \mathcal{N}_{ss}(P_{\Sigma}^{n_j,k_j})
\]
be the natural projection. Under the isomorphism of equivariant pairs
\[
(\mathcal{N}_\mu, \mathcal{G}(P_{\Sigma}^{n_0, \pm})) \cong (\mathcal{N}_{ss}(P_{\Sigma}^{n_0, \pm}), \mathcal{G}(P_{\Sigma}^{n_0, \pm}) \times \prod_{j=1}^r (\mathcal{N}_{ss}(P_{\Sigma}^{n_j,k_j}), \mathcal{G}_j)
\]
the \( G \)-equivariant vector bundle \( \mathbb{N}_\mu^R \) over \( \mathcal{N}_\mu \) is isomorphic to the \( \prod_{j=1}^r \mathcal{G}_j \)-equivariant vector bundle \( \bigoplus_{j=1}^r \mathbb{V}_{n_j,k_j} \) over \( \prod_{j=1}^r \mathcal{N}_{ss}(P_{\Sigma}^{n_j,k_j}) \). In other words, there is a homeomorphism of the total spaces of vector bundles
\[
(e\mathbb{N}_\mu^R)^{h\mathcal{G}} \cong \bigoplus_{j=1}^r \mathbb{V}_{n_j,k_j}^{h\mathcal{G}_j}
\]
which covers the homeomorphism of the bases
\[
\mathcal{N}_{ss}^{h\mathcal{G}} \cong \mathcal{N}_{ss}(P_{\Sigma}^{n_0, \pm})^{h\mathcal{G}(P_{\Sigma}^{n_0, \pm})} \times \prod_{j=1}^r \mathcal{N}_{ss}(P_{\Sigma}^{n_j,k_j})^{h\mathcal{G}_j}.
\]
So
\[
e\mathcal{G}(\mathbb{N}_\mu^R) = \prod_{j=1}^r e\mathcal{G}_j(\mathbb{V}_{n_j,k_j}).
\]

The \( \mathcal{G}_j \)-equivariant vector bundle \( \mathbb{V}_{n_j,k_j} \to \mathcal{N}_{ss}(P_{\Sigma}^{n_j,k_j}) \) descends to a \( U(n_j) \)-equivariant vector bundle \( V_{n_j,k_j} \) over \( X_{YM}(U(n_j)) \) with \( \bar{g} \), and \( e\mathcal{G}_j(\mathbb{V}_{n_j,k_j}) \) descends to \( eU(n_j)(V_{n_j,k_j}) \).

In the remainder of this subsection, we use rational coefficient \( \mathbb{Q} \).

**Lemma 22.** When \( n = 1, k > 0 \), the \( U(1) \)-action on \( V_{1,k} \) is trivial, and
\[
e_{U(1)}(V_{1,k}) = e(V_{1,k}) = 0.
\]

**Proof.** The \( U(1) \)-action is similar to that in Lemma 21.

We first review some discussion in [HLR, Section 6.2]. Given \( c \in U(1) \), let \( \bar{c} = c^{-1} \) denote the complex conjugate. Given \( V = (a_1, b_1, \ldots, a_\ell, b_\ell) \in U(1)^{2\ell} \), and \( V' = (a'_1, b'_1, \ldots, a'_\ell, b'_\ell) \), let
\[
\bar{V} = (\bar{a}_1, \bar{b}_1, \ldots, \bar{a}_\ell, \bar{b}_\ell), \quad VV' = (a_1a'_1, b_1b'_1, \ldots, a_\ell a'_\ell, b_\ell b'_\ell).
\]
The map $L \mapsto \text{Hom}(\mathcal{L}, \tau_C(\mathcal{L})) = \mathcal{L}^¥ \otimes \tau_C^¥$, where $\mathcal{L}$ is a degree $k > 0$ holomorphic line bundle over $\tilde{\Sigma}$, induces a map $\phi_Z : Z_{YM}^{\ell,i}(U(1))_k \rightarrow Z_{YM}^{\ell,i}(U(1))_{-2k}$ given by

$$(V, c, c', (-1)^k c, -2\sqrt{-1} \pi k)$$

$\mapsto (V V', (-1)^k c^2, V', (1)^k c^2, 4\sqrt{-1} \pi k), \quad i = 1,$

$$(V, d, c, V', (-1)^k d, c', -2\sqrt{-1} \pi k)$$

$\mapsto (V V', (-1)^k d^2, c', V' V, (1)^k d^2, c', 4\sqrt{-1} \pi k), \quad i = 2.$

It descends to a map $\phi_X : X_{YM}^{2\ell+i-1,0}(U(1))_k \rightarrow X_{YM}^{2\ell+i-1,0}(U(1))_{-2k}$ given by

$$(V_1, V_2, -2\sqrt{-1} k) \mapsto (\tau(V_1) \bar{V}_1, \tau(V_1) \bar{V}_2, 4\sqrt{-1} \pi k), \quad i = 1$$

$$(V_1, V_2, d, c, -2\sqrt{-1} k) \mapsto (\tau(V_1) \bar{V}_1, \tau(V_1) \bar{V}_2, (1)^k d^2, 1, 4\sqrt{-1} \pi k), \quad i = 2.$

The map $M \mapsto \tau^¥$, where $M$ is a degree $-2k$ holomorphic line bundle over $\tilde{\Sigma}$, induces an involution $\tilde{\tau}_Z : Z_{YM}^{\ell,i}(U(1))_{-2k} \rightarrow Z_{YM}^{\ell,i}(U(1))_{-2k}$ given by

$$(V, c, V', \bar{c}, 4\sqrt{-1} \pi k) \mapsto (\bar{V}', c \bar{V}, \bar{c}, 4\sqrt{-1} \pi k), \quad i = 1,$$

$$(V, d, c, V', \bar{d}, \bar{c}, 4\sqrt{-1} \pi k) \mapsto (\bar{V}', d \bar{c}, \bar{d}, \bar{V}, \bar{c}, 4\sqrt{-1} \pi k), \quad i = 2.$

It descends to an involution $\tilde{\tau}_X : X_{YM}^{2\ell+i-1,0}(U(1))_{-2k} \rightarrow X_{YM}^{2\ell+i-1,0}(U(1))_{-2k}$ given by

$$(V_1, V_2, 4\sqrt{-1} \pi k) \mapsto (\tau(V_2) \bar{V}_1, \tau(V_1) \bar{V}_2, 4\sqrt{-1} \pi k), \quad i = 1$$

$$(V_1, V_2, d, c, 4\sqrt{-1} \pi k) \mapsto (\tau(V_2) \bar{V}_1, \tau(V_1) \bar{V}_2, (1)^k d^2, 1, 4\sqrt{-1} \pi k), \quad i = 2.$

We have

$\text{Im} \phi_Z = Z_{YM}^{\ell,i}(U(1))_{-2k} \cong U(1)^{2\ell+i}$, $\quad \text{Im} \phi_X = X_{YM}^{2\ell+i-1,0}(U(1))_{-2k} \cong U(1)^{2\ell+i-1}$.

Let $U_k \rightarrow Z_{YM}^{\ell,i}(U(1))_{-2k}$ and $F_k \rightarrow X_{YM}^{2\ell+i-1,0}(U(1))_{-2k}$ be the vector bundles whose fiber over $M$ is $H^1(\tilde{\Sigma}, M)$. Then the involution $\tilde{\tau}_Z$ (resp. $\tilde{\tau}_X$) lifts to an involution on $U_k$ (resp. $F_k$):

$$(U_k)_M = (F_k)_M = H^1(\tilde{\Sigma}, M) \mapsto (U_k)_{\tau^¥} = (F_k)_{\tau^¥} = H^1(\tilde{\Sigma}, \tau^¥).$$

The fixed locus $U_k^{\tau^¥}$ (resp. $F_k^{\tau^¥}$) is a real vector bundle over $Z_{YM}^{\ell,i}(U(1))_{-2k}$ (resp. $X_{YM}^{2\ell+i-1,0}(U(1))_{-2k}$). Let $W_k \rightarrow Z_{YM}^{\ell,i}(U(1))_k$ be the vector bundle whose fiber over $\mathcal{L}$ is $H^1(\tilde{\Sigma}, \text{Hom}(\mathcal{L}, \tau_C(\mathcal{L})))^¥$. Then

$\phi^{\tau^¥}_U U_k^{\tau^¥} = W_k$, $\quad \phi^{\tau^¥}_X F_k^{\tau^¥} = V_{1,k}$, $\quad \text{rank}_k V_{1,k} = \text{rank}_k F_k^{\tau^¥} = \text{rank}_k F_k = 2k + 2\ell + i - 2$.

The $U(1)$-action on $\text{Hom}(\mathcal{L}, \tau_C(\mathcal{L}))$ is given by $t \cdot t^{-1}$, and thus the weights of the $U(1)$-action on $(V_1)_\mathcal{L} = H^1(\tilde{\Sigma}, \text{Hom}(\mathcal{L}, \tau_C(\mathcal{L})))^¥$ are also given by $t \cdot t^{-1}$ which is trivial. So $e(U_1(V_{1,k})) = e(V_{1,k}).$

We have

$\text{rank}_k F_k^{\tau^¥} = 2k + 2\ell + i - 2 > 2\ell + i - 1 = \text{dim}_R X_{YM}^{2\ell+i-1,0}(U(1))_{-2k}$.
since \( k > 0 \). So \( e(F^\pm_k) = 0 \). Therefore

\[
e(V_{1,k}) = \delta_X^\pm e(F^\pm_k) = 0.
\]

\[\square\]

**Proof of Theorem 13.** Part (ii) follows from Lemma 22. For part (i), recall that \( X_{YM}^{0,0}(U(n))_{\frac{k}{n}, \ldots, \frac{k}{n}} \) is empty unless \( \frac{k}{n} \in \mathbb{Z} \), and \( X_{YM}^{0,0}(U(n))_{d, \ldots, d} \) consists of a point if \( d \in \mathbb{Z} \). We need to prove that, for any positive integers \( n, d > 0 \),

\[
e_{U(n)}(V_{n,nd}) \in H^*_U(n)(X_{YM}^{0,0}(U(n))_{d, \ldots, d}; \mathbb{Q})
\]

is zero. Since \( Y_{n,d} := X_{YM}^{0,0}(U(n))_{d, \ldots, d} \) is a point, the inclusion of the maximal torus \( T = U(1)^n \subset U(n) \) induces an injective ring homomorphism

\[
\beta : H^*_U(n)(Y_{n,d}; \mathbb{Q}) \cong \mathbb{Q}[u_1, \ldots, u_n]^{S_n} \to H^*_Y(Y_{n,d}; \mathbb{Q}) \cong \mathbb{Q}[u_1, \ldots, u_n].
\]

So it suffices to show that \( e_T(V_{n,nd}) = \beta(e_{U(n)}(V_{n,nd})) \) is zero. We have

\[
V_{n,nd} = H^1\left( \mathbb{P}^1, \text{Hom}\left( \bigoplus_{i=1}^n \mathcal{L}_i, \bigoplus_{j=1}^n \tau_\mathcal{C}(\mathcal{L}_j) \right) \right)^\tau
\]

\[
\cong \bigoplus_{i<j} H^1\left( \mathbb{P}^1, \mathcal{L}_i^{-1} \otimes \tau_\mathcal{C}(\mathcal{L}_j) \right) \oplus \bigoplus_{i=1}^n H^1\left( \mathbb{P}^1, \mathcal{L}_i \otimes \tau_\mathcal{C}(\mathcal{L}_i) \right)^\tau
\]

where \( \mathcal{L}_i = \mathcal{O}_{\mathbb{P}^1}(d) \) for \( i = 1, \ldots, n \) and \( \tau_\mathcal{C}(\mathcal{L}_j) = \mathcal{O}_{\mathbb{P}^1}(-d) \) for \( j = 1, \ldots, n \). The weights of \( T \)-action on \( H^1\left( \mathbb{P}^1, \mathcal{L}_i \otimes \tau_\mathcal{C}(\mathcal{L}_j) \right) \) is \( t_j t_i^{-1} \), where \( (t_1, \ldots, t_n) \in U(1)^n = T \). Let

\[
V_\mathbb{C} = \bigoplus_{i<j} H^1\left( \mathbb{P}^1, \mathcal{L}_i^{-1} \otimes \tau_\mathcal{C}(\mathcal{L}_j) \right), \quad V_\mathbb{R} = \bigoplus_{i=1}^n H^1\left( \mathbb{P}^1, \mathcal{L}_i^{-1} \otimes \tau_\mathcal{C}(\mathcal{L}_i) \right)^\tau.
\]

Then

\[
V_{n,nd} = V_\mathbb{C} \oplus V_\mathbb{R}
\]

where \( V_\mathbb{C} \) is a complex vector space, \( V_\mathbb{R} \) is a real vector space on which \( T \)-acts trivially, and

\[
dim_\mathbb{R} V_{n,nd} = n^2(2d - 1), \quad \dim_\mathbb{C} V_\mathbb{C} = \frac{n(n - 1)}{2}(2d - 1), \quad \dim_\mathbb{R} V_\mathbb{R} = n(2d - 1).
\]

We have

\[
e_T(V_{n,nd}) = e_T(V_\mathbb{C}) e_T(V_\mathbb{R}),
\]

where

\[
e_T(V_\mathbb{C}) = \pm \prod_{i<j} (u_i - u_j)^{2d-1}, \quad e_T(V_\mathbb{R}) = 0,
\]

since \( \text{rank}_\mathbb{R} V_\mathbb{R} = \dim_\mathbb{R} V_\mathbb{R} > 0 = \dim_\mathbb{R} Y_{n,nd} \). Therefore \( e_T(V_{n,nd}) = 0 \). \[\square\]
By P5 of Lemma \(\text{II}\) the stratification is equivariantly Q-perfect if and only if
\[
\begin{align*}
P_t^Q(A_{ss}; Q) &= P_t^G(A; Q) - \sum_{\mu \in \Lambda'} t^{h_\mu} P_t^G(A_{\mu}; Q) \\
\end{align*}
\]
By A5 of Lemma \(\text{II}\) the stratification is equivariantly Q-antiperfect if and only if
\[
\begin{align*}
P_t^G(A_{ss}; Q) &= P_t^G(A; Q) + \sum_{\mu \in \Lambda'} t^{h_\mu-1} P_t^G(A_{\mu}; Q). \\
\end{align*}
\]

4.1. **Representation varieties for flat connections.** A flat \(G\)-connection on \(\Sigma\) gives rise to a homomorphism \(\pi_1(\Sigma) \to G\). Recall that
\[
\begin{align*}
\pi_1(\Sigma^f_1) &= \langle A_1, B_1, \ldots, A_\ell, B_\ell, C \mid \prod_{i=1}^\ell [A_i, B_i] = C^2 \rangle, \\
\pi_1(\Sigma^f_2) &= \langle A_1, B_1, \ldots, A_\ell, B_\ell, D, C \mid \prod_{i=1}^\ell [A_i, B_i] = CDC^{-1}D \rangle.
\end{align*}
\]

Representation varieties of flat \(U(n)\)-connections and \(SU(n)\)-connections on \(\Sigma^f_1\) and \(\Sigma^f_2\) are given by
\[
\begin{align*}
X_{\text{flat}}^{f,1}(U(n)) &= \{(V, c) \mid V \in U(n)^{2\ell}, c \in U(n), m(V) = c^2\} \\
X_{\text{flat}}^{f,1}(U(n))_{\pm 1} &= \{(V, c) \in X_{\text{flat}}^{f,1}(U(n)) \mid \det c = \pm 1\} \\
X_{\text{flat}}^{f,1}(SU(n)) &= \{(V, c) \mid V \in SU(n)^{2\ell}, c \in SU(n), m(V) = c^2\} \\
X_{\text{flat}}^{f,2}(U(n)) &= \{(V, d, c) \mid V \in U(n)^{2\ell}, d, c \in U(n), m(V) = cdc^{-1}d\} \\
X_{\text{flat}}^{f,2}(U(n))_{\pm 1} &= \{(V, d, c) \in X_{\text{flat}}^{f,2}(U(n)) \mid \det d = \pm 1\} \\
X_{\text{flat}}^{f,2}(SU(n)) &= \{(V, d, c) \mid V \in SU(n)^{2\ell}, d, c \in SU(n), m(V) = cdc^{-1}d\}
\end{align*}
\]
For \(i = 1, 2\),
\[
\text{Hom}(\pi_1(\Sigma^f_i), U(n))_{\pm 1} = X_{\text{flat}}^{f,i}(U(n))_{\pm 1}, \quad \text{Hom}(\pi_1(\Sigma^f_i), SU(n)) = X_{\text{flat}}^{f,i}(SU(n)).
\]

4.2. **Rank 2 case.**

**Proof of Theorem \(\text{III}\)** There are two possible principal \(U(2)\)-bundles \(P^2_\Sigma^+, P^2_\Sigma^-\) over the nonorientable surface \(\Sigma^f_i\). In notation in Section \(\text{III}\)
\[
\begin{align*}
I^0_2 &= \{(0, 0)\} \\
I^2_2(\Sigma^f_1) &= I^2_2(\Sigma^f_2) = \{(2r - 1, 1 - 2r) \mid r \in \mathbb{Z}_{>0}\}, \\
I^2_2(\Sigma^f_1) &= I^2_2(\Sigma^f_2) = \{(2r, -2r) \mid r \in \mathbb{Z}_{>0}\}.
\end{align*}
\]
So when \(\mathcal{A} = \mathcal{A}(P^2_\Sigma^{2,\pm}), \Lambda' = I^2_2(\Sigma)\).
Let \( \tilde{g} = 2\ell + i - 1 \) be the genus of the oriented double cover of \( \Sigma^\ell_\ell \). From [HL1] Example 7.5, the codimension of each stratum is
\[
d_{r,-r} = 2r + \tilde{g} - 1,
\]
and the equivariant Poincaré series for stratum \( \mu = (r,-r) \) is
\[
P^\ell_t(\mathcal{A}(\Sigma^\ell_\ell)_{r,-r}; \mathbb{Q}) = P^U_t\left(X_{YM}^{\ell,i}(U(2))_{r,-r}; \mathbb{Q}\right) = P^U_t\left(X_{YM}^0(U(1))_{r,-r}; \mathbb{Q}\right)
\]
\[
= P^U_t(1^{2\tilde{g}}) = \frac{(1 + t)^{2\tilde{g}}}{1 - t^2}.
\]
By [HL2] Theorem 2.5,
\[
P^\ell_t(\mathcal{A}; \mathbb{Q}) = P_t(B\mathcal{G}; \mathbb{Q}) = \frac{(1 + t)^{\tilde{g}}(1 + t^3)^{\tilde{g}}}{(1 - t^2)(1 - t^4)}.
\]
We have
\[
\sum_{r \text{ odd}} t^{d_{r,-r}-1} = \frac{t^\tilde{g}}{1 - t^4}, \quad \sum_{r \text{ even}} t^{d_{r,-r}-1} = \frac{t^{\tilde{g}+2}}{1 - t^4}.
\]
Therefore (23) is equivalent to the following identities
\[
P^U_t(\mathcal{Y}^\ell,i(U(2))_{(-1)}; \mathbb{Q}) = P_t(\mathcal{B} \mathcal{G}; \mathbb{Q}) + \sum_{r \text{ even}} t^{d_{r,-r}-1} P^\ell_t(\mathcal{A}(\Sigma^\ell_\ell)_{r,-r}; \mathbb{Q})
\]
\[
= \frac{(1 + t)^{\tilde{g}}}{(1 - t^2)(1 - t^4)} \left(1 + t^3\right)^{\tilde{g}} + t^{\tilde{g}+2}(1 + t)^{\tilde{g}},
\]
\[
P^U_t(\mathcal{Y}^\ell,i(U(2))_{(-1)+1}; \mathbb{Q}) = P_t(\mathcal{B} \mathcal{G}; \mathbb{Q}) + \sum_{r \text{ odd}} t^{d_{r,-r}-1} P^\ell_t(\mathcal{A}(\Sigma^\ell_\ell)_{r,-r}; \mathbb{Q})
\]
\[
= \frac{(1 + t)^{\tilde{g}}}{(1 - t^2)(1 - t^4)} \left(1 + t^3\right)^{\tilde{g}} + t^{\tilde{g}}(1 + t)^{\tilde{g}}.
\]
We now consider the principal \( SU(2) \)-bundles \( Q_{\Sigma^\ell_\ell}^2 \cong \Sigma^\ell_\ell \times SU(2) \) over the nonorientable surface \( \Sigma^\ell_\ell \) together with the gauge group \( \mathcal{G}' = Aut(Q_{\Sigma^\ell_\ell}^2) \) action. The set of Atiyah-Bott types is \( \Lambda' = \{(r,-r) \mid r \in \mathbb{Z}_{>0}, \ r = i \mod 2 \} \).

The codimension of \( \mathcal{A}'_{r,-r} \) in \( \mathcal{A}(Q_{\Sigma^\ell_\ell}^2) \) is the same as the codimension of \( \mathcal{A}_{r,-r} \) in \( \mathcal{A}(P_{\Sigma^\ell_\ell}^{2,+}) \), which is \( d_{r,-r} = 2r + \tilde{g} - 1 \).

We now derive the reduction formula for each stratum \( \mu = (r,-r), \ r > 0 \). The corresponding representation varieties are
\[
X_{YM}^{\ell,1}(SU(2))_{\mu} = \{(V, c, X) \in SU(2)^{2\ell+1} \times C_{\mu/2} \mid V \in (SU(2)X)^{2\ell}, \ \text{Ad}(c)X = -X, \ m(V) = \exp(X)c^2\},
\]
\[
X_{YM}^{\ell,2}(SU(2))_{\mu} = \{(V, d, c, X) \in SU(2)^{2\ell+2} \times C_{\mu/2} \mid (V, d) \in (SU(2)X)^{2\ell+1}, \ \text{Ad}(c)(X) = -X, \ m(V) = \exp(X)cd^{-1}d\}.
\]
where $C_{u/2}$ is the orbit of $X_\mu/2 = -\pi\sqrt{-1}\text{diag}(r,-r) \in su(2)$ under the Adjoint action of $SU(2)$ on $su(2)$. Let

$$\epsilon = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}.$$ 

Then $\text{Ad}(\epsilon)(X_\mu) = -X_\mu$. Note that

$$SU(2)_X = \{ \text{diag}(u, u^{-1}) | u \in U(1) \} \cong U(1), \quad \exp(X_\mu/2) = (-1)^\epsilon I_2.$$ 

For $\mu \in \Lambda' = \{(r,-r) | r > 0, r \equiv i \pmod{2} \}$, define $V^{t,i}(SU(2))_\mu$ as follows:

$$V^{t,1}(SU(2))_\mu = \{(V, c) \in (SU(2))^{2t+1} | V \in (SU(2))_{X_\mu}^{2t}, \quad \text{Ad}(c)X_\mu = -X_\mu, c^2 = -I_2\},$$

$$V^{t,2}(SU(2))_\mu = \{(V, d, c) \in (SU(2))^{2t+2} | (V, d) \in (SU(2))_{X_\mu}^{2t+1}, \quad \text{Ad}(c)(X_\mu) = -X_\mu, cdc^{-1}d = I_2\}$$

By argument similar to that in [HL1, Section 7], the following equivariant pairs are equivalent

$$(X_{YM}^{t,i}(SU(2))_\mu, SU(2)) \cong (V^{t,i}(SU(2))_\mu, (SU(2))_{X_\mu}) \cong (U(1)^{2t+i}, U(1))$$

where $U(1)$ acts on $U(1)^{2t} \times U(1)^i$ by

$$u \cdot (V, c) = (V, u^2c), \quad u \cdot (V, d, c) = (V, d, u^2c)$$

Thus, the $G'$-equivariant Poincaré series for stratum $\mathcal{A}'_{r,-r}$ is

$$P_t^{G'}(\mathcal{A}'_{r,-r}; Q) = P_t^{SU(2)}(X_{YM}^{t,i}(SU(2))_{r,-r}; Q) = P_t(U(1)^{\tilde{g}}; Q) = (1+t)^{\tilde{g}}, \quad \tilde{g} = 2t+i-1.$$ 

By [HL2, Theorem 2.5],

$$P_t^{G'}(\mathcal{A}(Q^2_{\Sigma}'; Q) = P_t(BG'; Q) = \frac{(1+t)^{\tilde{g}}}{1-t^4}.$$ 

Therefore [23] is equivalent to the following identities

$$P_t^{SU(2)}(X_{\text{flat}}^{t,1}(SU(2)); Q) = P_t(BG'; Q) + \sum_{r \text{ odd}} t^{d_{r,-r}^{-1}}(1+t)^{\tilde{g}} = \frac{(1+t)^{\tilde{g}} + t^{\tilde{g}}(1+t)^{\tilde{g}}}{1-t^4},$$

$$P_t^{SU(2)}(X_{\text{flat}}^{t,2}(SU(2)); Q) = P_t(BG'; Q) + \sum_{r \text{ even}} t^{d_{r,-r}^{-1}}(1+t)^{\tilde{g}} = \frac{(1+t)^{\tilde{g}} + t^{\tilde{g}+2}(1+t)^{\tilde{g}}}{1-t^4}.$$
4.3. Rank 3 case.

Proof of Theorem 19. There are two possible principal $U(3)$-bundles $P_{SU}^{3,+}$, $P_{SU}^{3,-}$ over the nonorientable surface $\Sigma^3_i$. In the notation of Section 3.4

$$I_3 = I^3_0 = \{(0,0,0)\} \cup \{(r,0,-r) \mid r \in \mathbb{Z}_{>0}\}$$

So when $A = A(P_{SU}^{3,\pm})$, $\Lambda' = \{(r,0,-r) \mid r \in \mathbb{Z}_{>0}\}$.

Let $\tilde{g} = 2\ell + i - 1$ be the genus of the oriented double cover of $\Sigma^3_i$. From Example 7.6], the codimension of each stratum is

$$d_{r,0,-r} = 4r + 3(\tilde{g} - 1),$$

and the equivariant Poincaré series for stratum $\mu = (r,0,-r)$ is

$$P^\mu_t (A(\Sigma^3_i)_{r,0,-r}; Q) = P_t U(3) \left( X_{YM}(U(3))_{r,0,-r}; Q \right) = P_t U(1) \times U(1) (U(1)^3) = \frac{(1 + t)^{3\tilde{g}}}{(1 - t^2)^2}.$$  

By [HL2 Theorem 2.5],

$$P^\mu_t (A; Q) = P_t (BG; Q) = \frac{(1 + t)^{2\tilde{g}} (1 + t^3)^{\tilde{g}} (1 + t^5)^{\tilde{g}}}{(1 - t^2)(1 - t^4)(1 - t^6)}.$$  

Therefore (23) is equivalent to the following identity

$$P_t U(3) \left( X_{flat}(U(3)) \pm ; Q \right) = P_t (BG; Q) + \sum_{r > 0} t^{d_{r,0,-r}} P^\mu_t (A(\Sigma^3_i)_{r,0,-r}; Q)$$

$$= \frac{(1 + t)^{\tilde{g}}}{(1 - t^2)(1 - t^4)(1 - t^6)} ((1 + t^3)^{\tilde{g}} (1 + t^5)^{\tilde{g}} + t^{3\tilde{g}} (1 + t + t^4)).$$

We now consider the principal $SU(3)$-bundles $Q_{\Sigma^3_i}^3 \cong \Sigma^3_i \times SU(3)$ over the nonorientable surface $\Sigma^3_i$ together with the gauge group $\mathcal{G}' = \text{Aut}(Q_{\Sigma^3_i}^3)$ action. The set of Atiyah-Bott types is $I^3_0$, so $\Lambda' = \{(r,0,-r) \mid r \in \mathbb{Z}_{>0}\}$. The codimension of $\mathcal{A}_{r,0,-r}$ in $A(Q_{\Sigma^3_i}^3)$ is the same as the codimension of $\mathcal{A}_{r,0,-r}$ in $A(P_{SU}^{3,+})$, which is $d_{r,0,-r} = 4r + 3(\tilde{g} - 1)$.

We now derive the reduction formula for each stratum $\mu = (r,0,-r)$. The corresponding representation varieties are

$$X_{YM}^1(SU(3))_{r,0,-r} = \{(V,c,X) \in SU(3)^{2\ell+1} \times C_{\mu/2} \mid V \in (SU(3)X)^{2\ell},$$

$$Ad(c)X = -X, m(V) = \exp(X)c\},$$

$$X_{YM}^2(SU(3))_{r,0,-r} = \{(V,d,c,X) \in SU(3)^{2\ell+2} \times C_{\mu/2} \mid (V,d) \in (SU(3)X)^{2\ell+1},$$

$$Ad(c)(X) = -X, m(V) = \exp(X)cd^{-1}d\}.$$

where $C_{\mu/2}$ is the orbit of $X_{\mu/2} = -\pi\sqrt{-1}\text{diag}(r,0,-r) \in \mathfrak{su}(3)$ under the Adjoint action of $SU(3)$ on $\mathfrak{su}(3)$. Let

$$\epsilon = \begin{pmatrix} 0 & 0 & 1 \\ 0 & -1 & 0 \\ 1 & 0 & 0 \end{pmatrix} \in SU(3).$$
Then \( \text{Ad}(\epsilon)X_{\mu} = -X_{\mu} \). Note that

\[
SU(3)X_{\mu} = \{ \text{diag}(u_1, u_2, u_3) \mid u_1, u_2, u_3 \in U(1), u_1u_2u_3 = 1 \} \cong U(1) \times U(1),
\]

\[\exp(X_{\mu}/2) = \text{diag}((-1)^\tau, 1, (-1)\tau).\]

Given \( \mu \in \Lambda' = \{(r, 0, -r) \mid r \in \mathbb{Z}_{>0}\} \), define \( V^{l,i}(SU(3))_{\mu} \) as follows:

\[
V^{l,1}(SU(3))_{\mu} = \{(V, c') \in (SU(3)X_{\mu})^{2l+1} \mid m(V) = \exp(X_{\mu}/2)(\epsilon c')^2\}
\]

\[
V^{l,2}(SU(3))_{\mu} = \{(V, d, c') \in (SU(3)X_{\mu})^{2l+2} \mid m(V) = \exp(X_{\mu}/2)\epsilon c'd(\epsilon c')^{-1}d\}.
\]

By argument similar to that in [HL1, Section 7], the following equivariant pairs are equivalent:

\[
(X_{\mu}^{l,i}(SU(3))_{\mu}, SU(3)) \cong (V^{l,i}(SU(3))_{\mu}, SU(3)X_{\mu})
\]

\[
\cong (Z^{l,i}_{X_{\mu}}(U(1)), r, U(1) \times U(1)) \cong (X_{YM}^{l,0}(U(1)), r, U(1))
\]

where \( Z^{l,i}_{X_{\mu}}(U(1)) \) is the symmetric representation varieties defined in [HL1] Section 4.4. Thus, the \( \mathcal{G}' \)-equivariant Poincaré series for stratum \( \Lambda'_{r,0,-r} \) is

\[
P_t^{\mathcal{G}'}(\Lambda'_{r,0,-r}; \mathbb{Q}) = P_t^{SU(3)}(X_{YM}^{l,i}(SU(3))_{r,0,-r}; \mathbb{Q}) = P_t^{U(1)}(X_{YM}^{l,0}(U(1)), r) = \frac{(1 + t)^{2\bar{\gamma}}}{1 - t^2}.
\]

By [HL2, Theorem 2.5],

\[
P_t^{\mathcal{G}'}(A(Q^3_{\gamma}); \mathbb{Q}) = P_t(BG'_{\gamma}; \mathbb{Q}) = \frac{(1 + t^3)^{2\bar{\gamma}}(1 + t^5)^{2\bar{\gamma}}}{(1 - t^4)(1 - t^6)}.
\]

Therefore [20] is equivalent to the following identity

\[
P_t^{SU(3)}(X_{\text{flat}}^{l,i}(SU(3)); \mathbb{Q}) = P_t(BG'_{\gamma}; \mathbb{Q}) + \sum_{r>0} t^{4r+3(\bar{\gamma}-1)-1} \frac{(1 + t)^{2\bar{\gamma}}}{1 - t^2}
\]

\[
= \frac{(1 + t^3)^{2\bar{\gamma}}(1 + t^5)^{2\bar{\gamma}}}{(1 - t^4)(1 - t^6)} + \frac{(1 + t)^{2\bar{\gamma}}}{(1 - t^4)(1 - t^6)}
\]

\[\square\]
