INTRODUCTION

Menstruation is a physiological phenomenon which has been related to multiple psychosocial elements.¹ Three out of four women experience physical and mental symptoms before menstruation.² Premenstrual syndrome (PMS) is used to describe an array of predictable physical, cognitive, affective, and behavioral symptoms that occur cyclically during the luteal phase of the menstrual cycle and resolve quickly in a few days at the onset of menstruation.²⁻⁵ Multiple factors like hormonal, genetic, psychosocial and lifestyle factors may be effective on development of PMS.⁶ PMS is an important problem that affects women and causes loss of labor, can affect quality of life, sleep quality, family relations and work productivity.⁷⁻¹¹ Women with PMS frequently complain of poor sleep quality and many women report changes in sleep quality and sleep problems such as insomnia, hypersonmia and nightmares.¹²⁻¹⁴

There is a dearth of literature on PMS symptoms and sleep quality and there are insufficient studies on PMS symptoms and sleep quality.¹⁵ Due to this dearth of studies, especially in the Indian scenario, authors decided to study the association between sleep quality and PMS symptoms. The study was conducted in nurses from two...
tertiary general hospitals as the sample would be similar in work load and stressors.

**METHODS**

This was a cross-sectional study conducted in nursing staff aged 25-50 years and working in two tertiary general hospitals i.e. K.E.M. Hospital and Lokmanya Tilak Municipal General Hospital, Mumbai. Institutional ethics committee was obtained for the study. Nursing staff were approached directly to obtain information for the same and one on one interviews were conducted. Written and valid informed consent was taken prior to the study.

**Inclusion criteria**

- Nursing staff between the age of 20-50 years that were having a regular menstrual cycle.

**Exclusion criteria**

- Nursing staff on hormonal therapy and oral contraceptives.

Nursing staff which major gynecological problems that would affect menstruation were also excluded from the study. The minimum optimum sample size obtained by using appropriate statistical formula resulted to be 440. As the total number of nurses in K.E.M. Hospital was found to be twice of that in the other center, authors decided on 450 as a sample size with 300 nurses from K.E.M. Hospital and 150 from Lokmanya Tilak Municipal General Hospital.

The questionnaires used for the study were:

Premenstrual Tension Syndrome Observer Rating Scale (PMTS): The scale includes 11 domains with a total maximum score of 40. It has a reliability coefficient 0.97 and has been widely used in studies on PMS.16

Pittsburgh Sleep Quality Index (PSQI): The scale measures sleep quality and disturbance retrospectively over a 1-month period using self-reports. Although the PSQI has been used in a variety of populations, published psychometric data are limited. It has good internal consistency and construct validity and reliability coefficient of 0.8 has been reported.17

Both the scales were administered in a single setting to the participants.

**Statistical analysis**

Descriptive statistics with frequency and percentage representing categorical variables were used while mean and standard deviation was used for the continuous variables. The comparison of continuous variables was done using Spearman Rank Correlation or nominal scale Chi square test. The statistical analysis was doing using a software (Statistical Package for Social Sciences, version SPSS20 software).

**RESULTS**

The subjects were 450 nursing staff from both the centers which has in fact a total of 1130 nursing staff. Authors wanted an equal sample size from different age groups. Hence, authors interviewed 150 nursing staff each from three age groups viz. 25-35 years, 35-45 years and > 45 years across both centers. On assessing socio-demographic data, all the three age groups were well matched on the average age of menarche, number of children and regularity of the menstrual cycle.

Table 1 illustrates the mean scores on the PMTS and all its items in the three age groups. The maximum mean PMTS score 17.6±6.46 was found in age group 35-45 years. Depressed mood, affective lability, irritability and impaired concentration were symptoms that had higher scores across the age groups.

| Variables                        | Age        | 25-35 years | 35-45 years | > 45 years |
|----------------------------------|------------|-------------|-------------|------------|
| Total score of PMTS             | Range 0-40 | 10.67       | 17.6        | 10.67      |
|                                 | Mean 0.79  | 1.08        | 1.2         | 1.03       |
| Depressed mood                   | Mean 0.79  | 1.08        | 1.2         | 1.03       |
| Anxiety/Tension                  | Mean 0.79  | 1.08        | 1.2         | 1.03       |
| Affective lability               | Mean 0.79  | 1.08        | 1.2         | 1.03       |
| Irritability                     | Mean 0.79  | 1.08        | 1.2         | 1.03       |
| Decreased interest               | Mean 0.79  | 1.08        | 1.2         | 1.03       |
| Concentration difficulties       | Mean 0.79  | 1.08        | 1.2         | 1.03       |
| Lack of energy                   | Mean 0.79  | 1.08        | 1.2         | 1.03       |
| Eating habits                    | Mean 0.79  | 1.08        | 1.2         | 1.03       |
| Sleeping habits                  | Mean 0.79  | 1.08        | 1.2         | 1.03       |
| Overwhelmed                      | Mean 0.79  | 1.08        | 1.2         | 1.03       |
| Physical symptoms                | Mean 0.79  | 1.08        | 1.2         | 1.03       |

International Journal of Reproduction, Contraception, Obstetrics and Gynecology

Volume 8 · Issue 4 · Page 1488
Table 2 shows the severity of premenstrual symptoms in the age groups graded as minimal (0-10), mild (11-20), moderate (21-30) and severe (31-40). None of the participants reported minimal symptoms. Most participants had mild symptoms in both the groups (p=0.0019).

Table 2: Severity of scores on the PMTS scale.

| Severity Scores on PMTS | 25-35 years | 35-45 years | > 45 years |
|-------------------------|-------------|-------------|------------|
| Mild (11-20)            | 124         | 103         | 130        |
| Moderate (21-30)        | 21          | 37          | 14         |
| Severe (31-40)          | 5           | 10          | 6          |

X² = 16.9615, p=0.0019 (significant)

Spearman correlation analysis between total scores of PMTS and that of PSQI showed a positive correlation for all groups (Table 3).

Table 3: Correlation between PMTS and PSQI scores.

| Age group   | Correlation between PMTS and PSQI scores | r value | p value |
|-------------|------------------------------------------|---------|---------|
| 25-35 years |                                          | 0.317   | < 0.0001* |
| 35-45 years |                                          | 0.332   | < 0.0001* |
| > 45 years  |                                          | 0.406   | < 0.0001* |

DISCUSSION

In the study, when the mean age at menarche was calculated, it came out to be 12.55 (25-35 years), 12.41 (35-45 years) and 12.05 (>45 years). In a study conducted in school girls aged 6-17 years, the mean age of menarche was found to be 12.4 years which is very close to our finding.18

In the current study, there was a positive significant correlation between total score of PMSS and scores of PSQI, which was in accordance with literature. In women with PMS, it has been noted the sleep quality worsened and as the PMS symptoms exacerbated, the sleep quality (except for the appetite change) negatively changed, as well.19 In a study on female students receiving education at a high school, they determined a significantly poor sleep quality in 75.6% of subjects with PMS compared to 58.8% in girls without PMS. In the same study, a positive correlation was reported between total score of PMSS and mean score of PSQI.20

It has been reported in literature that experiencing the symptoms of bloating, fatigue, irritability, depressive thoughts and depressive affect more frequently in the premenstrual period maybe thus related to the poor sleep quality and the poor sleep quality could be exacerbating the premenstrual symptoms which constitutes a never-ending vicious cycle.21 The current study has some limitations. It was cross sectional and done in a circumscribed population across 2 centers. Multiple factors that are confounding and that would affect the results of the study have not been evaluated. Both sleep and premenstrual symptoms have been influenced by a wide variety of factors that have not been considered in the study. Active intervention directed towards sleep quality and menstrual psychoeducation could improve performance at work and also reduce distress in nurses. Further studies on sleep parameters, menstruation and PMS are warranted in diverse populations.

Funding: No funding sources
Conflict of interest: None declared
Ethical approval: The study was approved by the Institutional Ethics Committee
