Brain-derived neurotrophic factor (BDNF) exerts its survival-promoting effects on photoreceptors and retinal ganglion cells, however, delivery systems with little-to-no side effect are needed to sustain its controlled release and long-term efficacy. Our previous studies demonstrated that adipose-derived stem cells (ADSCs) are ideal delivery systems for gene therapy; moreover, ADSCs present unique properties like migration to damaged tissue sites, immunomodulation and anti-inflammation. Herein, we propose to employ ADSCs as the BDNF gene delivery vehicle. Different Analyses like flow cytometry, differentiation and cell proliferation assays etc demonstrated that BDNF were successfully transduced into ADSCs and the stemness of ADSCs was maintained even with the transduction. Real Time PCR and Western blot were used to measure mRNA and protein expressions of the BDNF-transduced ADSCs. The results demonstrated that the BDNF expression level of the lentiviral-BDNF transduced ADSCs is significantly increased and, moreover, enhanced the expression of other neurotrophic and downstream signaling factors. The data suggest that ADSCs are a reliable delivery vehicle for BDNF and could be used for the treatment of various diseases.

Keywords: Brain-derived neurotrophic factor, Adipose-derived mesenchymal stem cells, Lentiviral transduction, Drug delivery, Neural protection

Introduction

Brain-derived neurotrophic factor (BDNF), a member of neurotrophic factor family, was first isolated from pig brain extract by German neurobiologist BARDE in 1982. BDNF has a larger distribution of its mRNA-expressing cells and a wider distribution of receptors in comparison to other neurotrophic factors (1, 2). Researches have confirmed that BDNF has the ability to inhibit the progression of neuronal degenerations, plays an important role in neuronal survival and maintenance of the biological actions by activation of its intracellular pathways and relative receptors, especially its cognitive receptor-TrkB (3). Although the biological effect of BDNF on neuronal survival and its physiological mechanism has been researched systematically, broader applications of BDNF requires exogenous BDNF injection because the endogenous BDNF expression in diseased models is much lower than that of the normal controls (4). However, exogenous BDNF injected with systemic administration can’t penetrate the blood-retina or blood-brain barrier due to its size...
(5) and direct local injection, although effective, cause serious side effects. For example, although intravitreal injection of BDNF is effective for the treatment of retinitis pigmentosa (1), repeated injection is needed due to its short half-life in vivo, which easily causes risks of endophthalmitis and retinal detachment (6). Therefore, finding a reliable exogenous BDNF delivery system is the key for wider clinical applications (7).

Adipose-derived mesenchymal stem cells (ADSCs) are a population of mesenchymal stem cells (MSCs) isolated from adipose tissue. Like any other MSCs, ADSCs are featured with adherence to plastics, expressing specific cell surface markers and having multipotent differentiation potential (8). Moreover, ADSCs are attracting more and more attention for its unique advantages. For example, the amount of ADSCs obtained from adipose tissue is 100 to 1,000 times that of bone marrow stem cells in the same volume of tissue (9, 10). Meanwhile, the acquisition of adipose tissue is much simpler with less invasive and painful operation, such as abdominal fat aspiration. Therefore, ADSCs can be easily obtained in large quantities, cultured and expanded in vitro. Researches have shown that ADSCs have the potential to migrate to injured tissue sites, and provide therapeutic repair of the damaged tissues. Implantation of ADSCs could reduce immune rejections due to its low immunogenicity (11, 12). What’s more, it has been reported that ADSCs can successfully pass the blood-brain or blood-retina barrier. Therefore, ADSCs are attractive candidates in gene delivery systems (13). In addition to act as a gene delivery vehicle, the therapeutic effects of ADSCs themselves by replacing damaged cells through cellular differentiation, cellular factor secretion, regulation of inflammatory cytokines, and creation of favorable environment for regeneration will be synergistic to the gene therapy efforts.

Herein, in consideration of the protection effects of BDNF on nerve cells and the advantages of ADSCs as a gene delivery carrier, murine ADSCs were isolated, cultured, characterized and transduced with lentiviral vectors carrying the BDNF exogene. Flow cytometric sorting and G418 resistance selection was conducted to obtain a stable overexpressing-BDNF new cell line BDNF-ADSCs. Different analyses, such as flow cytometry, differentiation capacity, cell proliferation assay, colony forming unit assay, were undertaken to investigate whether BDNF transduction would affect the stemness maintenance of the ADSCs. Meanwhile, western-blot and Real-time PCR were employed to study the anti-inflammation property of the ADSCs and the release of other neurotropic factors induced by BDNF in BDNF-ADSCs.

Materials and Methods

Isolation of adipose-derived stem cells

The procedure of isolation fats and cells from C57BL/6 mice has been approved by the Ethics Committee of Dalian University of Technology. ADSCs were isolated from the abdominal fats of C57BL/6 mice. The abdominal fats were harvested and washed with D-Hank’s buffer to remove red blood cells, and then cut into tiny pieces at room temperature (RT) with the fur and any blood vessels dissected away. The pieces were incubated in digestion buffer (0.1% collagenase type 1 in Hank’s buffer) at 37°C with shaking at 120 rpm for 1.5 hrs. Then the digested solution was filtered with 70 μm cell strainers to remove undigestated fragments and ADSCs were collected by centrifugation at 600 g for 15 min, and then transferred to 75 cm² culture flasks (Corning) with DMEM/F12 complete medium, containing 10% fetal bovine serum (FBS), 1% Penicillin-Streptomycin-Amphotericin B (PSA) and 1% L-Glutamine. Culture medium was replaced every 2~3 days, and cells were routinely passaged when they reached 80% confluence. ADSCs passages 4~6 were used for different experiments.

Transduction

BDNF lentiviral vector [pLV[Exp]-EGFP/Neo-EF1A>mBdnf] were acquired by restriction endonuclease digestions and gene recombination. 293T cells were co-transfected with a plasmid expressing BDNF, carrying an enhanced green fluorescent protein gene (EGFP) and a neomycin resistance gene (neo) for selective marker to generate BDNF lentiviral particles. The ADSCs, seeded in 6-well plates with a density of 10⁶ cells per well, were incubated with 50~100*10⁶ lentiviral particles (multiplicity of infection (MOI) of 50~100) for 24 hrs before the supernatant was removed and replaced with fresh growth medium. The ADSCs were observed for EGFP expression under microscope after 48 hrs of transduction. During transduction, polybrene was added (5 μg/ml) to improve the transfection efficiency.

Establishment of stable BDNF-transduced ADSC cell line

Flow cytometric sorting and G418 resistance selection was conducted for the establishment of stable BDNF-transduced ADSC cell lines. Transduced ADSCs expressing EGFP were sorted by the fluorescence-activated cell sorting (BD, FACSJAZZ) in purity mode, and sorting was gated by forward and side scatter to eliminate the un-transduced cells. The sorted cells were then seeded in...
Flow cytometry

ADSCs and BDNF-ADSCs were analyzed by flow cytometry (BD FACSCalibur. FACS101) for cell surface marker expression. All the antibodies were purchased from eBioscience Inc. Cells were harvested in 0.25% trypsin and washed in flow cytometry buffer (PBS, 2% BSA). The cells with a concentration of 10^7 cells/ml were incubated for 90 min in flow cytometry buffer containing fluorescein conjugated monoclonal antibodies and the cell surface marker antigens respectively: CD29-FITC, CD31-FITC, CD34-FITC, Scal-1-FITC, CD11-PE, and CD45-PE. Cells were then fixed with 1% paraformaldehyde for 30 min and analyzed by BD FACS101. The FSC-H Signal was used to measure cell sizes and cell volume.

Differentiation analysis

ADSCs and BDNF-ADSCs were cultured in 6-well plates (Costar, New York, USA) at a density of 2×10^5 cells per well. When reached at approximately 90% confluency, the cells were cultured in osteogenic and adipogenic differentiation medium respectively with medium replaced every 3 days for 3 weeks. Osteogenic differentiation medium was made by complete medium supplemented with 100 nM dexamethasone, 10 mM b-glycerolphosphate, 50 μM L-ascorbic acid 2-phosphate sesquimagnesium salt, and 50 ng/ml L-thyroxine sodium pentahydrate. Adipogenic differentiation medium was made with complete medium supplemented with 5 μg/ml insulin, 50 μM indomethacin, 1 μM dexamethasone and 0.5 mM 3-isobutyl-1-methyl-xanthine. For adipogenic differentiation, the cells were washed with PBS, fixed with 10% formalin (Sigma) for 20 minutes at RT, washed again with PBS, stained with Oil Red O (Sigma) for 20 minutes at RT, and washed with PBS until wash was clear. For the detection of osteogenesis, the cells were washed with PBS, fixed with 10% formalin for 20 minutes at RT, washed with deionized (DI) water, stained with Alizarin Red (Sigma) for 20 minutes at RT, and washed with DI water until it was clear. Images were acquired at 10× for adipogenic differentiation and 4× for osteogenic differentiation on microscope.

In vitro cell proliferation assay

ADSCs and BDNF-ADSCs were plated in 24 wells plate at a density of 10^3 cells per well and cultured for 2 weeks. The fold-increase in cell number was analyzed every 2 days throughout the culture period.

Colony forming unit assay

ADSCs and BDNF-ADSCs were seeded onto 10 cm cell culture plates (Corning, USA) in 5 replicates at a density of 100 cells per plate. Growth media was replaced every 3 days. After 2 weeks, the cells were washed with PBS, stained with 3% crystal violet in 100% methanol for 30 minutes at RT, and then washed with DI water at least 3 times to remove unstained crystal violet. All colonies greater than 2 mm in diameter were counted.

Extraction of total RNA

Total RNA was extracted from cultured cells using the RNA extraction kit (Takara, Japan). The concentration and purity of RNA were determined on Nanodrop 2000 (Thermo Scientific, Braunschweig, Germany), and RNA with high purity (the ratios of A260/A230 for the total RNA obtained higher than 2.0, and their ratios of A260/A280 were more than 1.8) was used for reverse transcription. All RNA samples were stored at −80°C until further use.

Real-time PCR

RNA was reverse transcribed into cDNA to a final volume of 20 μl using PrimeScript™ RT reagent Kit (Takara, Japan). All cDNA samples were stored at −80°C until further processing. Real-time PCR was performed with the LightCycler (Roche Diagnostics, Mannheim, Germany) to measure and compare the mRNA expression levels of different factors between ADSCs and BDNF-ADSCs. For the real time-PCR analysis, a total volume of 10 μl was used following the manual instructions. Briefly, real-time PCR was operated with the two-step method, and melting curves were recorded during the 60 to 95°C melting process with continual fluorescence data acquisition. The melting curves were generated during denaturation step at 95°C followed by the cooling of PCR products at 60°C and the fluorescence signals were collected continuously from 60 to 95°C as the temperature increased at 0.2°C per second. All reactions were repeated at least three times. Primer sequences used are listed in Table 1. The 2^−ΔΔCT Method was used for the quantity calculations.

Western-blot

For western blot analysis, cell pellets were suspended in radioimmunoprecipitation assay (RIPA) buffer (P0013B; Beyotime) containing PMSF (STS06; Beyotime), and samples were homogenized in a glass homogenizer at 4°C for 20 min. Insoluble materials were pelleted by centrifugi-

Fig. 1. Cell morphology and growth profiles of ADSCs and BDNF-ADSCs.

Cell morphology and growth kinetics of ADSCs and BDNF-ADSCs.

As shown in Fig. 1, the cell morphology, which is fibroblasts-like, of the BDNF-ADSCs was consistent with the un-transfected ADSCs, moreover, the green fluorescence shown by BDNF-ADSCs proved that ADSCs was successfully transfected with BDNF plasmid. Meanwhile, measurement of the proliferative capacity of the BDNF-ADSCs demonstrated that the growth curve of the BDNF-ADSCs is like that of ADSCs in general although the maximum fold change is not as high as that of ADSCs.

Surface antigen analysis on ADSCs and BDNF-ADSCs by flow cytometry.

Both ADSCs and BDNF-ADSCs were cultured, stained, and analyzed for cell surface marker expression. ADSC surface markers CD29, Sca1; hematopoietic markers CD34 and CD45; phagocytic lineage marker CD11b; and endothelial marker CD31 were tested by flow cytometry. As shown in Fig. 2A, both ADSCs and BDNF-ADSCs were positive for specific antigen markers of ADSCs like CD29 and NK/ILC markers like ScaI-1, while they were negative for endothelial marker CD31, hematopoietic markers CD45, CD34 and macrophage marker CD11b. Meanwhile, the cell sizes of both ADSCs and BDNF-ADSCs were also measured based on the forward scatter signal of flow cytometry, and data in Fig. 2B demonstrated that there were no significant differences between the cell sizes of ADSCs and BDNF-ADSCs (p=0.13, t-test, n=6).
**Fig. 2.** (A) Cell surface marker profiles of ADSCs and BDNF-ADSCs. Murine ADSCs and BDNF-ADSCs were stained with stem cells’ surface markers CD29, Sca1; hematopoietic markers CD34 and CD45; phagocytic lineage marker CD11b; and endothelial marker CD31 and analyzed by flow cytometry. Green lines represent ADSCs stained with CD29-FITC, CD31-FITC, CD34-FITC, Sca1-FITC; Red lines show ADSCs stained with CD45-PE, CD11b-PE; Blue lines represent BDNF-ADSCs stained with the same antibody as ADSCs for comparison, and purple area shows the respective IgG isotype control for each antibody. (B) Cell size based on forward scatter signal of flow cytometry (p=0.13, t-test, n=6).

**Fig. 3.** Qualitative and quantitative adipogenic and osteogenic differentiation of ADSCs and BDNF-ADSCs. Cells were incubated in adipogenic or osteogenic differentiation media for 21 days and stained with Oil Red O and Alizarin Red respectively. The inserts in osteogenesis of ADSCs panels emphasize the calcium nodus produced by the ADSCs. **** means much statistically significant (p<0.0001, n=3).

**Differentiation assays for ADSCs and BDNF-ADSCs**

BDNF-ADSCs and ADSCs were cultured in adipogenic and osteogenic differentiation medium respectively for 3 weeks, and then stained with Oil Red O and Alizarin Red to test their differentiation efficiency. The results (Fig. 3) demonstrated that BDNF-ADSCs preserve the ability of multi-lineage potential, although the potential is not as strong as the un-transduced ADSCs.

Colony forming unit assay for ADSCs and BDNF-ADSCs

ADSCs and BDNF-ADSCs were assessed for their self-renewal ability by the colony forming unit (CFU) assay. All colonies greater than 2 mm in diameter were counted. Fig. 4 showed that BDNF-ADSCs still has the self-renewal capacity, although the number and density of the units formed are smaller in comparison to the un-transfected ADSCs control.

Real-time polymerase chain reaction

Real-time polymerase chain reaction (PCR) assay was performed to analyze the levels of BDNF, related signaling pathways gene IKK and inflammatory cytokines (IL-1α, IL-1β, TNF-a, IL-6 and IL-10) expressed by ADSCs and BDNF-ADSCs. The housekeeping gene b-actin was used as internal reference. Quantification was calculated using $2^{-\Delta\Delta CT}$ method. As illustrated in Fig. 5, the mRNA expression levels of BDNF, related signaling pathways gene IKK and anti-inflammatory cytokine IL-1α are significantly higher in BDNF-ADSCs in comparison to those expressed in un-transfected ADSCs control.

Western-blot analysis

The protein expressions of neurotrophic factors BDNF, NGF, CNTF, bFGF in BDNF-ADSCs and ADSCs were normalized to control β-actin. The grayscale of bands were semi-quantified by AlphaView Software, Version 3.4.0.0. Western blot analysis data as shown in Fig. 6 revealed that all the neurotrophic factors BDNF, NGF, CNTF, bFGF tested had significant increased expression in BDNF-ADSCs while compared to those in ADSCs.

Discussion

The present study was carried out to investigate whether the ADSCs transduced with BDNF still keep their stemness abilities and characteristics, and whether ADSCs, alongside acting as the gene delivery vehicle of BDNF, could contribute synergistic therapeutic effects to those of BDNF. The results demonstrated that the BDNF-ADSCs displayed all the characteristics that defined for mesenchymal stem cells in vitro (8, 14), which are mononuclear cell population adherent to plastic culture surfaces, fibroblast-like and spindle shaped, possess osteogenic and adipogenic differentiation potential (Fig. 3). Meanwhile, the BDNF-ADSCs, like MSCs, are positive for stem cell surface markers CD29 and Scal, and negative for hematopoietic markers CD45, CD31, CD34 and macrophage marker CD11b (Fig. 2) (15, 16). However, The data from Fig. 1, 3 and 4 showed that, while BDNF-ADSCs still proliferate, differentiate and could form single colonies like un-transfected ADSCs, the rate was slowed down which...
could be explained by the increased burden of the addition of exogenous BDNF (17, 18), while it has been demonstrated that lentiviral eGFP transduction did not affect the proliferation, differentiation and CFU forming abilities of ADSCs (19).

Real-time PCR analysis (Fig. 5) revealed that, along with the increased BDNF mRNA expression level in BDNF-ADSCs, the mRNA expression level of interleukin (IL)-1α and inhibitor of nuclear factor kappa-B kinase (IKK) were also significantly increased (p<0.001, n=3) in comparison with those expressed in un-transduced ADSCs. IL-1α is one of the most well studied members of interleukin family, and is recognized as an important player in cancer and other inflammatory diseases (20, 21). IL-1α is thought to be a dual-function cytokine that represents both nuclear and extracellular functions and active in inflammation and immune response processes (22). Research conducted by Redondo-Castro et al. (23) found out that mesenchymal stem cells pre-conditioned with IL-1α increases expression of trophic factor G-CSF and induces a reduction in the secretion of inflammatory mediators in LPS-activated microglial cells, which suggests that BDNF-ADSCs with a higher expression of IL-1α may be beneficial to damaged neuronal recovery and survival. IKK plays an important role in the signaling pathway induced by the combination of BDNF and tyrosine kinase receptor B (TrkB). Phosphorylation of IKK activates nuclear survival factor NFkB, thus exerting its anti-apoptotic effect (24, 25).

The results obtained from western-blots experiment (Fig. 6) showed that the expression of other neurotrophic factors, such as NGF, CNTF, bFGF, was also increase in BDNF-ADSC when compared to that of wild type ADSCs. Besides the anti-apoptotic effects, BDNF has been known to help induce the release of other neurotrophic factors, such as NGF, CNTF, bFGF, was also increase in BDNF-ADSCs, the mRNA expression level of interleukin family, and is recognized as an important player in cancer and other inflammatory diseases (20, 21).

In conclusion, the transduction of BDNF into ADSCs did not change the stem cell characteristics of ADSCs, Moreover, the BDNF helped induce expression of the immune response factors like IKK and IL-1α, and other neurotrophic factors like NGF, CNTF, bFGF. ADSCs could break through the blood-brain barrier and migrate to the damaged tissue, and its low immunogenicity could reduce immune rejection. Therefore, the ADSCs are ideal gene delivery vectors for BDNF. Meanwhile, the anti-inflammation and immune regulation properties of ADSCs could be synergistic to the therapeutic effects of BDNF.
