We investigate the classical gravitational tests for the six-dimensional Kaluza-Klein model with spherical (of a radius $a$) compactification of the internal space. The model contains also a bare multidimensional cosmological constant $\Lambda_6$. The matter, which corresponds to this ansatz, can be simulated by a perfect fluid with the vacuum equation of state in the external space and an arbitrary equation of state with the parameter $\omega_1$ in the internal space. For example, $\omega_1 = 1$ and $\omega_1 = 2$ correspond to the monopole two-forms and the Casimir effect, respectively. In the particular case $\Lambda_6 = 0$, the parameter $\omega_1$ is also absent: $\omega_1 = 0$. In the weak-field approximation, we perturb the background ansatz by a point-like mass. We demonstrate that in the case $\omega_1 > 0$ the perturbed metric coefficients have the Yukawa type corrections with respect to the usual Newtonian gravitational potential. The inverse square law experiments restrict the parameters of the model: $a/\sqrt{\omega_1} \lesssim 6 \times 10^{-3}$ cm. Therefore, in the Solar system the parameterized post-Newtonian parameter $\gamma$ is equal to 1 with very high accuracy. Thus, our model satisfies the gravitational experiments (the deflection of light and the time delay of radar echoes) at the same level of accuracy as General Relativity. We demonstrate also that our background matter provides the stable compactification of the internal space in the case $\omega_1 > 0$. However, if $\omega_1 = 0$, then the parameterized post-Newtonian parameter $\gamma = 1/3$, which strongly contradicts the observations.

I. INTRODUCTION

Any physical theory is correct until it does not conflict with the experimental data. Obviously, the Kaluza-Klein model is no exception to this rule. There is a number of well-known gravitational experiments in the Solar system, e.g., the deflection of light, the perihelion shift and the time delay of radar echoes (the Shapiro time-delay effect). In the weak-field limit, all these effects can be expressed via parameterized post-Newtonian (PPN) parameters $\beta$ and $\gamma$ \cite{1, 2}. These parameters take different values in different gravitational theories. There are strict experimental restrictions on these parameters \cite{3, 6}. The tightest constraint on $\gamma$ comes from the Shapiro time-delay experiment using the Cassini spacecraft: $\gamma - 1 = (2.1 \pm 2.3) \times 10^{-5}$. General Relativity is in good agreement with all gravitational experiments \cite{7}. Here, the PPN parameters $\beta = 1$ and $\gamma = 1$. The Kaluza-Klein model should also be tested by the above-mentioned experiments.

In our previous papers \cite{8–10} we have investigated this problem in the case of toroidal compactification of internal spaces. We have supposed that in the absence of gravitating masses the metrics is a flat one. Gravitating compact objects (point-like masses or extended massive bodies) perturb this metrics, and we have considered these perturbations in the weak-field approximation. First, we have shown that in the case of three-dimensional external/our space and dust-like equations of state \cite{11} in the external and internal spaces, the PPN parameter $\gamma = 1/(D - 2)$, where $D$ is a total number of spatial dimensions. Obviously, $D = 3$ (i.e. the General Relativity case) is the only value which does not contradict the observations \cite{8}. Second, in the papers \cite{9, 10}, we have investigated the exact soliton solutions. In these solutions a gravitating source is uniformly smeared over the internal space and the non-relativistic gravitational potential exactly coincides with the Newtonian one. Here, we have found a class of solutions which are indistinguishable from General Relativity. We have called such solutions latent solitons. Black strings and black branes belong to this class. They have the dust-like equation of state $p_0 = 0$ in the external space and the relativistic equation of state $p_1 = -\varepsilon/2$ in the internal space. It is known (see \cite{10, 12}) that in the case of the three-dimensional external space with a dust-like perfect fluid, this combination of equations of state in the external and internal spaces does not spoil the internal space stabilization. Moreover, we have shown also that the number $d_0 = 3$ of the external dimensions is unique. Therefore, there is no problem for black strings and black branes to satisfy the gravitational experiments in the Solar system at the same level of accuracy as General Relativity. However, the main problem with the black strings/branes is to find a physically reasonable mechanism which can explain how the ordinary particles forming the astrophysical objects can

\footnotesize

‡Electronic address: ai.zhuk2@rambler.ru
acquire rather specific equations of state \( p_i = -\varepsilon/2 \) (tension) in the internal spaces. Thus, in the case of toroidal compactification, on the one hand we arrive at the contradiction with the experimental data for the physically reasonable gravitating source in the form of a point-like mass, on the other hand we have no problem with the experiments for black strings/branes but arrive at very strange equation of state in the internal spaces. How common is this problem for the Kaluza-Klein models?

To understand it, in the present paper we investigate a model with spherical compactification of the internal space. Therefore, in contrast to the previous case the background metrics is not flat but has a topology \( \mathbb{R} \times \mathbb{R}^3 \times S^2 \). To make the internal space curved, we must introduce a background matter. We show that this matter can be simulated by a perfect fluid with the vacuum equation of state in the external space and an arbitrary equation of state with the parameter \( \omega_1 \) in the internal space. Our model contains also a bare multidimensional cosmological constant \( \Lambda_6 \). If \( \Lambda_6 \) is absent, then the parameter \( \omega_1 \) is also equal to zero, i.e. the perfect fluid has the dust-like equation of state in the internal space. We perturb this background by a point-like mass and calculate the perturbed metric coefficients. In appendix C we prove that the background matter which satisfies the condition \( \omega_1 > 0 \) stabilizes the internal two-sphere. The main results are summarized and discussed in section III.

II. BACKGROUND SOLUTION AND PERTURBATIONS

To start with, let us consider a factorizable six-dimensional static background metrics

\[
ds^2 = c^2 dt^2 - dx^2 - dy^2 - dz^2 - a^2 (\xi^2 + \sin^2 \xi d\eta^2),
\]

where the energy density and pressures in the external space are respectively

\[
\rho = \Lambda_6, \quad p_i = \omega_1 \varepsilon, \quad \omega_1 = -1,
\]

and internal spaces are respectively

\[
\rho_1 = \omega_1 \varepsilon, \quad \omega_1 = -1.
\]

The paper is organized as follows. In section II we define the background metrics and matter for the Kaluza-Klein model with flat external space-time and spherical compactification of the internal space. We also include a bare six-dimensional cosmological constant \( \Lambda_6 \). We perturb this background by a point-like mass and calculate the corresponding perturbed metric coefficients. Then, we define the conditions which provide the agreement with the observations. One of these conditions is the positivity of the equation of state parameter \( \omega_1 \) in the internal space. In appendixes A and B we present formulas for the components of the Ricci tensor and, with the help of them, investigate the relations between the perturbed metric coefficients. In appendix C we prove that the background matter which satisfies the condition \( \omega_1 > 0 \) stabilizes the internal two-sphere. The main results are summarized and discussed in section III.
that is we have the vacuum-like equation of state in the external space, but the equation of state in the internal space is not fixed:

\[ \bar{\rho}_1 = \omega_1 \bar{\varepsilon} \quad \Rightarrow \quad \omega_1 = \frac{\Lambda_6}{1/ (\kappa a^2) - \Lambda_6} \Leftrightarrow \Lambda_6 = \frac{\omega_1}{\omega_1 + 1} \frac{1}{\kappa a^2}, \quad (7) \]

i.e. \( \omega_1 \) is arbitrary. The case \( \omega_1 = 0 \) automatically results in \( \Lambda_6 = 0 \). Choosing different values of \( \omega_1 \) (with fixed \( \omega_0 = -1 \)), we can simulate different forms of matter. For example, \( \omega_1 = 1 \) and \( \omega_1 = 2 \) correspond to the monopole perturbation (the Freund-Rubin scheme of compactification) and the Casimir effect, respectively (see appendix C and [12,14,15]).

Now, we perturb our background ansatz by a point-like massive source with non-relativistic rest mass \( \rho \). We suppose that the matter source is uniformly smeared over the internal space [10]. Hence, multidimensional \( \rho \) and three-dimensional \( \rho_3 \) rest mass densities are connected as follows:

\[ \rho = \rho_3(r_3) / (4\pi a^2) \quad (8) \]

In the case of a point-like mass \( m, \rho_3(r_3) = m \delta(r_3) \), where \( r_3 = |r_3| = \sqrt{x^2 + y^2 + z^2} \). In the non-relativistic approximation the only nonzero component of the energy-momentum tensor of the point-like mass is \( T_0^0 \approx \rho c^2 \) and up to linear in perturbations terms \( T_{00} \approx \rho c^2 \). Concerning the energy-momentum tensor of the background matter, we suppose that perturbation does not change the equations of state in the external and internal spaces, i.e. \( \omega_0 \) and \( \omega_1 \) are constants. For example, if we had a monopole form-fields (\( \omega_0 = -1, \omega_1 = 1 \)) before the perturbation, the same type of matter we shall have after the perturbation. Therefore, the energy-momentum tensor of the perturbed background is

\[ \hat{T}_{ik} \approx \begin{cases} 
(\varepsilon + \varepsilon^1) g_{ik}, & i, k = 0, \ldots, 3; \\
-\omega_1 (\varepsilon + \varepsilon^1) g_{ik}, & i, k = 4, 5,
\end{cases} \quad (8) \]

where the correction \( \varepsilon^1 \) is of the same order of magnitude as the perturbation \( \rho c^2 \). The trace of (8) is \( T \approx 2(2 - \omega_1)(\varepsilon + \varepsilon^1) \).

We suppose that the perturbed metrics preserves its diagonal form. Obviously, the off-diagonal coefficients \( g_{0\alpha}, \alpha = 1, \ldots, 5 \), are absent for the static metrics. It is also clear that in the case of uniformly smeared (over the internal space) perturbation, all metric coefficients depend only on \( x, y, z \) (see, e.g., [18]), and the metric structure of the internal space does not change, i.e. \( F = E \sin^2 \xi \). It is not difficult to show that in this case the spatial part of the external metrics can be diagonalized by coordinate transformations. Moreover, if we additionally assume the spherical symmetry of the perturbation with respect to the external space, then all metric coefficients depend on \( r_3 \) and \( B(r_3) = C(r_3) = D(r_3) \). Therefore, the perturbed metrics reads

\[ ds^2 = Ac^2 dt^2 + Bdx^2 + Cdy^2 + Ddz^2 + Ed\xi^2 + Fd\eta^2 \quad (9) \]

with

\[ A \approx 1 + A^1(r_3), \quad B \approx -1 + B^1(r_3), \]
\[ C \approx -1 + C^1(r_3), \quad D \approx -1 + D^1(r_3), \]
\[ E \approx -\alpha^2 + E^1(r_3), \quad F \approx -\alpha^2 \sin^2 \xi + F^1(r_3), \quad (10) \]

where we take into account the spherical symmetry of the perturbation with respect to the external space. All perturbed metric coefficients \( A^1, B^1, C^1, D^1, E^1, F^1 \) are of the order of \( \varepsilon^1 \). To find these coefficients we should solve the Einstein equation

\[ R_{ik} = \kappa \left( T_{ik} - \frac{1}{4} Tg_{ik} - \frac{1}{2} \Lambda g_{ik} \right), \quad (11) \]

where the energy-momentum tensor \( T_{ik} \) is the sum of the perturbed background \( \hat{T}_{ik} \) and the energy-momentum tensor of the perturbation \( T_{ik} \). Then, we get the system

\[ \Delta_3 A^1 = \kappa \omega_1 \varepsilon^1 + \frac{3}{2} \kappa \rho c^2, \]
\[ \Delta_3 B^1 = \Delta_3 C^1 = \Delta_3 D^1 = -\kappa \omega_1 \varepsilon^1 + \frac{1}{2} \kappa \rho c^2, \quad (12) \]
\[ \Delta_3 E^1 = (2 + \omega_1) \kappa a^2 \varepsilon^1 - \frac{2}{a^2} E^1 + \frac{1}{2} \kappa \rho c^2 a^2, \quad (13) \]

where \( \Delta_3 \) is the three-dimensional Laplace operator. Eqs. (12) show that \( B^1 = C^1 = D^1 \) and the relation \( B^1 = (1/3) A^1 \) takes place only in the particular case \( \omega_1 = 0 \) (the case of [15]). With the help of Eqs. (13) and (12) we obtain

\[ \Delta_3 E^1 = \frac{a^2}{2} \left( \Delta_3 A^1 - \Delta_3 B^1 \right) = \frac{a^2}{2} (2\kappa \omega_1 \varepsilon^1 + \kappa \rho c^2). \quad (14) \]

The comparison of (13) and (14) yields

\[ \kappa \varepsilon^1 = E^1 / a^2. \quad (15) \]

The substitution of this relation back into (13) gives

\[ \omega_1 \frac{a^2}{2} E^1 = \Delta_3 E^1 - \frac{1}{2} \kappa \rho c^2 a^2. \quad (16) \]

Then, taking also into account (15), we can rewrite Eqs. (12) in the form

\[ \Delta_3 \left( A^1 - \frac{E^1}{a^2} \right) = \kappa \rho c^2, \quad \Delta_3 \left( B^1 + \frac{E^1}{a^2} \right) = \kappa \rho c^2. \quad (17) \]

In the case of smeared extra dimensions the rest mass density is \( \rho = (m / (4\pi a^2)) \delta(r_3) \). Hence, the Eq. (16) can be rewritten as follows

\[ \Delta_3 E^1 - \lambda^2 E^1 = -\nu \delta(r_3), \quad (18) \]

where parameters \( \lambda^2 \equiv a^2 / \omega_1 \) and \( \nu \equiv -a^2 4\pi G_N m / c^2 \). We also introduce the Newton gravitational constant via the relation

\[ 4\pi G_N = \frac{S_5 G_6}{4\pi a^2}, \quad (19) \]
which exactly coincides with the formula (58) in [8] where
the volume of the internal space \( V_2 = 4\pi a^2 \). It is well
known that to get the solution of (18) with the boundary
condition \( E^1 \to 0 \) for \( r_3 \to +\infty \) the parameter \( \lambda^2 \) should
be positive, i.e. the equation of state parameter \( \omega_1 \) should
satisfy the condition

\[ \omega_1 > 0 . \] (20)

Additionally, we can conclude from (7) that the bare six-
dimensional cosmological constant is also positive: \( \Lambda_6 > 0 \). In the case of positive \( \omega_1 \), the solution of (18) reads

\[ E^1 = \frac{\nu}{4\pi r_3} e^{-r_3/\lambda} = \frac{2\varphi_N}{c^2} e^{-r_3/\lambda}, \] (21)

where the Newtonian potential \( \varphi_N = -G_N m/r_3 \). Now, we
can easily get the solutions of Eqs. (17):

\[ A^1 = \frac{2\varphi_N}{c^2} + \frac{E^1}{a^2} = \frac{2\varphi_N}{c^2} \left[ 1 + \frac{1}{2} \exp \left( -r_3/\lambda \right) \right]. \] (22)

\[ B^1 = \frac{2\varphi_N}{c^2} - \frac{E^1}{a^2} = \frac{2\varphi_N}{c^2} \left[ 1 - \frac{1}{2} \exp \left( -r_3/\lambda \right) \right]. \] (23)

It is well known that the metric correction term \( A^1 \sim O(1/c^2) \) describes the non-relativistic gravitational po-
tential: \( A^1 = 2\varphi/c^2 \). Therefore, this potential acquires the
Yukawa correction term:

\[ \varphi = \varphi_N \left[ 1 + \frac{1}{2} \exp \left( -r_3/\lambda \right) \right]. \] (24)

The parameter \( \lambda \) defines the characteristic range of
Yukawa interaction. There is a strong restriction on this
parameter from the inverse square law experiments. For the
Yukawa parameter \( \alpha = 1/2 \) (which is the prefactor
in front of the exponent) the upper limit is [13]

\[ \lambda_{\text{max}} = \left( \frac{a}{\sqrt{\omega_1}} \right)_{\text{max}} \approx 6 \times 10^{-3} \text{ cm} , \] (25)

which provides the upper limit on the size \( a \) of the internal
two-sphere. The ratio \( B^1/A^1 \) goes to 1 in the limit
\( r_3 \gg \lambda \). For example, for the gravitational experiments
in the Solar system (the deflection of light and the time
delay of radar echoes) we can take \( r_3 \gtrsim r_\odot \sim 7 \times 10^{10} \text{ cm} \).
Then, for \( \lambda \lessgtr 6 \times 10^{-3} \text{ cm} \), we get \( r_3/\lambda \gtrsim 10^{13} \).
Therefore, with very high accuracy we can drop the Yukawa
correction term, and the parameterized post-Newtonian pa-
ter parameter \( \gamma \) is equal to 1 similar to General Relativity, and
we arrive at the concordance with the above-mentioned
gravitational experiments.

Obviously, for \( r_3 \ll \lambda \) the ratio \( B^1/A^1 \) goes to 1/3.
For the limiting case \( \omega_1 = 0 \Rightarrow \lambda \to +\infty \), this ratio
is exactly equal to 1/3. Therefore, the PPN parameter
\( \gamma = 1/3 \) which strongly contradicts the observations
(see also [17] for the case of non-smeared extra dimen-
sions). Exactly the same result we have for the models
with toroidal compactification of the internal spaces and
a point-like gravitating mass with the dust-like equations
of state in the external and internal spaces (see [8]–[10]
where \( \gamma = 1/(D - 2) \)). The Eq. (17) shows that \( \omega_1 = 0 \)
for the models with \( \Lambda_6 = 0 \). On the other hand, the
parameter \( \omega_1 \) defines the Yukawa mass squared (see the
Eq. (18)). Therefore, the positiveness of \( \Lambda_6 \) is the nec-
essary condition for the positiveness of the Yukawa mass
squared in the models with spherical compactification.
In appendix C we show that this is also the sufficient
condition of the internal space stabilization.

### III. CONCLUSION AND DISCUSSION

To calculate the perihelion shift of planets and the de-
flexion of light by the Sun, we need the metric coeffi-
cients in the weak-field limit. To perform the corre-
sponding calculations in General Relativity, we usually
assume that the background space-time metrics is flat
and perturbation has the form of a point-like mass (see,
for example, [7]). In our paper [8], we generalized this proce-
dure to the case of the extra dimensions. We considered
flat background in the form of the Kaluza-Klein model
with toroidal compactification of the internal space, and
perturbed this background by a point-like mass. We
found that obtained formulas lead to a strong contradic-
tion with the observations. The exact soliton solutions
considered in [9, 10] confirmed this result: the physi-
cally reasonable point-like massive source contradicts the
observations. Among these solutions, latent solitons, in
particular, black strings and black branes, are the only
astrophysical objects which satisfy the gravitational ex-
periments at the same level of accuracy as General Rela-
tivity. However, their matter source does not correspond
to a point-like mass with the dust-like equations of state
both in the external and internal spaces. In contrast, it
has a very strange relativistic equation of state (tension)
in the internal space. Obviously, such equation of state
requires careful physical justification. Up to now, we do
not aware about it.

Further, trying to understand the underlying problem
with a point-like massive source, we investigated non-
linear \( f(R) \) models with toroidal compactification of the
internal spaces [19]. Unfortunately, such modification of
gravity does not save the situation. Here, to demonstrate
the agreement with the observations at the same level of
accuracy as General Relativity, the gravitating massive
source should also have tension in the internal spaces [20].

In the present paper, to avoid this problem, we consid-
ered the Kaluza-Klein model where the internal space is
not flat but has the form of a two-sphere with the radius
\( a \). Similar to General Relativity, the external space-time
background remains flat and the perturbation takes the
form of a point-like mass. Additionally, we included a
bare multidimensional cosmological constant and found
that this is a crucial point for our model because it gives
a possibility to stabilize the internal space. First, we
found the background matter which corresponds to our
metric ansatz. It was shown that this matter can be sim-
ulated by a perfect fluid with the vacuum equation of state in the external space and an arbitrary equation of state in the internal space. Then, in the weak-field approximation we perturbed the background matter and metrics by a point-like mass. We assumed that such perturbation does not change the equations of state. We have shown that in the case $\omega_1 > 0$ the perturbed metric coefficients have the Yukawa type corrections with respect to the usual Newtonian gravitational potential. The inverse square law experiments restrict such corrections and provide the following bound on the parameters of the model: $a/\sqrt{\omega_1} \lesssim 6 \times 10^{-3}$ cm. Obviously, in the Solar system we can drop the Yukawa correction terms with very high accuracy, and the parameterized post-Newtonian parameter $\gamma$ is equal to 1 similar to General Relativity. Therefore, our model satisfies the gravitational experiments (the deflection of light and the time delay of radar echoes) at the same level of accuracy as General Relativity. We have also found that our background matter provides the stable compactification of the internal space in the case $\omega_1 > 0$. This is the main feature of our model with $\omega_1 > 0$. Neither the models with toroidal compactification in [8, 10, 19] nor the model with spherical compactification and $\omega_1 = 0$ (see also [17]) have this property. Therefore, we can achieve the agreement with the observations in models with the stable compactification of the internal spaces. This is the main conclusion of our paper. The usual drawback of such models consists in fine tuning of their parameters.

It is worth noting that the problem of stabilization of the internal spaces was extensively investigated in the literature in the framework of multidimensional cosmological models including the Freund-Rubin and Casimir mechanisms (see, e.g., [8, 13, 21, 22]). Obviously, in this case we deal with the time-dependent multidimensional metrics, where the four-dimensional part corresponds usually either to Friedmann or to DeSitter space-time. Our present paper is devoted to the classical gravitational tests in the weak-field limit, e.g., in the Solar system, for Kaluza-Klein models. Clearly, this is an astrophysical problem with the static gravitational field. Stabilization of the internal spaces in such astrophysical models was not investigated sufficiently in the literature. As far as we know, the six-dimensional Kaluza-Klein model with spherical compactification of two extra dimensions is considered in detail with respect to observations in the Solar system for the first time. We produce the consistent generalization of the weak-field approximation in General Relativity to the considered multidimensional case and to obtain solutions of Einstein equations in corresponding orders of approximation. Then, we explicitly demonstrate the crucial role of a bare six-dimensional cosmological constant and restrict the parameters, proceeding from the experimental constraints. The background matter is taken in the form of the perfect fluid with initially arbitrary equations of state. This choice is much more general than both Freund-Rubin two-forms and Casimir effect, which represent only particular cases. Our analysis shows that without the multidimensional cosmological constant these two mechanisms can not provide the flat external space and at the same time the curved (and stabilized!) internal space. Certainly, it is not evident from the very beginning. Moreover, our results enable us to estimate quantitatively the effect of extra dimensions on gravitational tests and, vice versa, to put experimental limitations on the parameters of our multidimensional model.

ACKNOWLEDGEMENTS

Appendix A: Components of the Ricci tensor

In this appendix we consider the six-dimensional spacetime metrics of the form (9):

$$ds^2 = A^2 dt^2 + B dx^2 + C dy^2 + D dz^2 + Ed\xi^2 + F d\eta^2,$$

where the metric coefficients $A, B, C, D, E$ and $F$ satisfy the decomposition (10). Now, we define the corresponding components of the Ricci tensor up to linear correction terms. In appendixes A and B we assume that correction terms $A^1, B^1, C^1, D^1, E^1$ and $F^1$ may depend on all coordinates of the five-dimensional space.

Diagonal components

$$R_{00} \approx \frac{1}{2} \left[ \triangle_3 A^1 + \frac{1}{a^2} \triangle_\xi A^1 \right]. \quad (A1)$$

Here we introduce the Laplace operators:

$$\triangle_3 \equiv \frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2} + \frac{\partial^2}{\partial z^2},$$

$$\triangle_\xi \eta \equiv \frac{\partial^2}{\partial \xi^2} + \frac{\partial^2}{\partial \eta^2} + \frac{1}{\sin^2 \xi} \frac{\partial^2}{\partial \xi^2}. \quad (A2)$$

For $R_{11}, R_{22}$ and $R_{33}$ we obtain respectively:

$$R_{11} \approx -\frac{1}{2} \left[ -\triangle_3 B^1 - \frac{1}{a^2} \triangle_\xi B^1 + \left( A^1 + B^1 - C^1 - D^1 - E^1 \frac{F^1}{a^2 - \frac{F^1}{a^2 \sin^2 \xi}} \right)_{xx} \right], \quad (A3)$$
\[ R_{22} \approx -\frac{1}{2} \left[ -\Delta_3 C^1 - \frac{1}{a^2} \Delta_3 \xi \eta C^1 \right. \\
+ \left. \left( A^1 + C^1 - B^1 - D^1 - \frac{E^1}{a^2} - \frac{F^1}{a^2 \sin^2 \xi} \right) \right]_{yy}, \]  
(A4)

\[ R_{33} \approx -\frac{1}{2} \left[ -\Delta_3 D^1 - \frac{1}{a^2} \Delta_3 \xi \eta D^1 \right. \\
+ \left. \left( A^1 + D^1 - B^1 - C^1 - \frac{E^1}{a^2} - \frac{F^1}{a^2 \sin^2 \xi} \right) \right]_{zz}. \]  
(A5)

Indexes denote everywhere the corresponding partial derivatives (e.g., \( A_{x} \equiv \partial A/\partial x \)). The components \( R_{44} \) and \( R_{55} \) read respectively:

\[ R_{44} \approx 1 - \frac{1}{2} \left\{ \left( A^1 - B^1 - C^1 - D^1 \right)_{\xi \xi} - \Delta_3 E^1 \right. \\
- \frac{E^1_{yy}}{a^2 \sin^2 \xi} - \frac{1}{2} \left( \frac{1}{a^2 \sin^2 \xi} \left( F^1_{\xi \xi} - 2 \frac{\cos \xi}{\sin \xi} \xi F^1_{\xi} \right) \\
- \frac{2}{\sin \xi} \left( F^1_{\xi \xi} - 2 \frac{\cos \xi}{\sin \xi} F^1 \right) \right\} - \frac{\sin \xi}{a^2 \cos \xi} \left( F^1_{\xi} - 2 \frac{\cos \xi}{\sin \xi} F^1 \right). \]  
(A6)

\[ R_{55} \approx \sin^2 \xi - \frac{1}{2} \left\{ (A^1 - B^1 - C^1 - D^1)_{\eta \eta} - \Delta_3 F^1 \right. \\
- \frac{E^1_{\eta \eta}}{a^2} - \frac{1}{2} \left( F^1_{\xi \eta} - 2 \frac{\cos \xi}{\sin \xi} F^1_{\xi} \right) \\
+ \frac{\sin \xi}{2} \left( \frac{E^1_{\xi \eta}}{a^2} + (A^1 - B^1 - C^1 - D^1) \right) \\
+ \frac{\cos \xi}{a^2 \sin \xi} \left( F^1_{\xi \eta} - 2 \frac{\cos \xi}{\sin \xi} F^1 \right) \\
+ \frac{1}{a^2 \cos \xi} \left( F^1_{\xi} - 2 \frac{\cos \xi}{\sin \xi} F^1 \right) \right\}. \]  
(A7)

### Off-diagonal components

Obviously, for the static metrics the components \( R_{01}, R_{02}, R_{03}, R_{04}, R_{05} \) are identically equal to zero. Let us now calculate the remaining 10 off-diagonal components:

\[ R_{12} \approx \left( -\frac{1}{2} A^1 + \frac{1}{2} D^1 + \frac{1}{2 a^2 E^1} + \frac{1}{2 a^2 \sin^2 \xi} F^1 \right)_{xy}, \]  
(A8)

\[ R_{13} \approx \left( -\frac{1}{2} A^1 + \frac{1}{2} C^1 + \frac{1}{2 a^2 E^1} + \frac{1}{2 a^2 \sin^2 \xi} F^1 \right)_{xz}, \]  
(A9)

\[ R_{23} \approx \left( -\frac{1}{2} A^1 + \frac{1}{2} B^1 + \frac{1}{2 a^2 E^1} + \frac{1}{2 a^2 \sin^2 \xi} F^1 \right)_{yz}. \]  
(A10)

\[ R_{15} \approx \left( -\frac{1}{2} A^1 + \frac{1}{2} C^1 + \frac{1}{2 D^1} + \frac{1}{2 a^2 E^1} \right)_{\eta y}, \]  
(A11)

\[ R_{25} \approx \left( -\frac{1}{2} A^1 + \frac{1}{2} B^1 + \frac{1}{2 D^1} + \frac{1}{2 a^2 E^1} \right)_{\eta y}, \]  
(A12)

\[ R_{35} \approx \left( -\frac{1}{2} A^1 + \frac{1}{2} B^1 + \frac{1}{2 C^1} + \frac{1}{2 a^2 E^1} \right)_{\eta y}, \]  
(A13)

\[ R_{14} \approx \left( \frac{1}{2} (-A^1 + C^1 + D^1) \eta + \frac{1}{2 a^2 \sin^2 \xi} F^1 \right)_{x}, \]  
(A14)

\[ R_{24} \approx \left( \frac{1}{2} (-A^1 + B^1 + D^1) \eta + \frac{1}{2 a^2 \sin^2 \xi} F^1 \right)_{y}, \]  
(A15)

\[ R_{34} \approx \left( \frac{1}{2} (-A^1 + B^1 + C^1) \eta + \frac{1}{2 a^2 \sin^2 \xi} F^1 \right)_{z}, \]  
(A16)

\[ R_{45} \approx \left( \frac{1}{2} (-A^1 + B^1 + C^1 + D^1) \eta + \frac{1}{2 a^2 \sin^2 \xi} F^1 \right). \]  
(A17)

### Appendix B: Relations between metric coefficients

First, we investigate expressions (A8)-(A10) in the case \( R_{12} = R_{13} = R_{23} = 0 \). It can be easily seen that the equation \( R_{12} = 0 \) has a solution

\[ -\frac{1}{2} A^1 + \frac{1}{2} D^1 + \frac{1}{2 a^2 E^1} + \frac{1}{2 a^2 \sin^2 \xi} F^1 = G_1(z, \xi, \eta) f_1(x) + G_2(z, \xi, \eta) f_2(y), \]
where \( G_1(z, \xi, \eta), G_2(z, \xi, \eta), f_1(x) \) and \( f_2(y) \) are arbitrary functions. We also assume that in the limit \( |x|, |y|, |z| \rightarrow +\infty \) the perturbed metrics reduces to the background one. Thus, all perturbations \( A^1, B^1, C^1, D^1, E^1 \) and \( F^1 \) as well as their partial derivatives vanish in this limit. Therefore, the right hand side of the above equation is equal to zero. Similar reasoning can be applied to equations \( R_{13} = 0 \) and \( R_{23} = 0 \). Then, we arrive at the following relations:

\[ B^1 = C^1 = D^1 = A^1 - \frac{1}{a^2} E^1 - \frac{1}{a^2 \sin^2 \xi} F^1. \]  
(B1)
We consider models where the Einstein equation for all off-diagonal components is reduced to

\[ R_{ik} = 0 \quad \text{for} \quad i \neq k. \quad (B2) \]

We want to analyze these equations for components \(A_{11})-(A_{17})\) with regard to the relations \((B1)\).

First, it can be easily seen that Einstein equations \((B2)\) for components \(A_{14})-A_{16}\) give

\[-A_{\xi}^{1} + B_{\xi}^{1} + C_{\xi}^{1} + \frac{1}{a^{2} \sin^{2} \xi} F_{\xi}^{1} = \frac{\cos \xi}{a^{2} \sin \xi} E^{1}\]

\[-\frac{\cos \xi}{a^{2} \sin^{2} \xi} F^{1} = C_{\xi}(\xi, \eta), \quad (B3)\]

where \(C_{\xi}(\xi, \eta)\) is an arbitrary function. From the boundary conditions at \(|x|, |y|, |z| \to +\infty\) we find that \(C_{\xi}(\xi, \eta) = 0\). Taking it into account, we get from \((B1)\) and \((B2)\) respectively

\[- A_{\xi}^{1} + B_{\xi}^{1} + \frac{1}{a^{2} \sin^{2} \xi} F_{\xi}^{1} = -\frac{1}{a^{2}} E^{1} \quad (B4)\]

and

\[- A_{\xi}^{1} + B_{\xi}^{1} + \frac{1}{a^{2} \sin^{2} \xi} F_{\xi}^{1} - \frac{\cos \xi}{a^{2} \sin \xi} E_{\xi}^{1} - \frac{\cos \xi}{a^{2} \sin \xi} F_{\xi}^{1} = -B_{\xi}^{1}. \quad (B5)\]

Differentiating \((B4)\) with respect to \(\xi\), we obtain

\[- A_{\xi}^{1} + B_{\xi}^{1} + \frac{1}{a^{2} \sin^{2} \xi} F_{\xi}^{1} - \frac{2 \cos \xi}{a^{2} \sin \xi} F_{\xi}^{1} = -\frac{1}{a^{2}} E_{\xi}^{1}. \quad (B6)\]

Subtraction \((B6)\) from \((B5)\) yields

\[- \frac{1}{a^{2} \sin^{2} \xi} F_{\xi}^{1} = -B_{\xi}^{1} \tan \xi + \frac{1}{a^{2}} E_{\xi}^{1} \tan \xi + \frac{1}{a^{2}} E_{\xi}^{1}. \quad (B7)\]

Let us consider now the case of the smeared extra dimensions.

**Smeared extra dimensions.**

In this case, the matter source is uniformly smeared over the internal space \([23]\). It results in the metric coefficients \(A^{1}, B^{1}, C^{1}, D^{1}\) and \(E^{1}\) depending only on the external coordinates \(x, y, \) and \(z \) \([18]\). We require that the off-diagonal components must be like \((B2)\). Then, equations \(R_{15} = R_{25} = R_{35} = R_{45} = 0\) (where these off-diagonal components are defined by \(A_{11})-(A_{17})\)) are automatically satisfied. It can be easily seen from \((B1)\) that the coefficient \(F^{1} \sim \sin^{2} \xi\). Moreover, to satisfy the Eq. \((B7)\), it should have the form

\[ F^{1} = E^{1} \sin^{2} \xi. \quad (B8)\]

Therefore, \((B1)\) can be rewritten in the form

\[- A_{\xi}^{1} + B_{\xi}^{1} + \frac{2}{a^{2}} E_{\xi}^{1} = 0. \quad (B9)\]

**Appendix C: Stabilization of the internal two-sphere**

To consider the stabilization of the internal space, we suppose that the scale factor of the internal space becomes a function of time: \(a \to a(t)\). Then, the energy conservation equation has the simple integral for the energy density (see, e.g., (2.9) in \([12]\))

\[ T_{\xi\eta}^{\nu \nu} = 0 \quad \Rightarrow \quad \varepsilon(t) = \frac{\varepsilon_{c}}{(a(t))^{2(\omega_{1}+1)}}, \quad (C1)\]

where \(\varepsilon_{c}\) is a constant of integration. Let us introduce the following notation:

\[ a(t) = e^{\beta(t)} = e^{\beta_{0} + \beta(t)} = a e^{\beta(t)}, \quad (C2)\]

where \(a = \exp(\beta_{0}) = \text{const}\) is some initial value or a position of the stable compactification. The latter corresponds to a minimum of an effective potential (see below). Hence, the Eq. \((C1)\) for the energy density reads

\[ \varepsilon(t) = \varepsilon_{c} e^{-2(\omega_{1}+1)\beta(t)}, \quad \varepsilon_{c} = \frac{\varepsilon_{c}}{a^{2(\omega_{1}+1)}} = \text{const}. \quad (C3)\]

The mechanism of the internal space stabilization was described in detail in \([12]\). To get such stabilization, we should find a minimum (which corresponds to \(\beta = 0\)) of the effective potential

\[ U_{\text{eff}}(\beta) = e^{-2\beta} \left[ -\frac{3}{2} \dot{R}_{1} e^{-2\beta} + \kappa \Lambda_{0} + \kappa \varepsilon_{c} e^{-2(\omega_{1}+1)\beta} \right], \quad (C4)\]

where \(\dot{R}_{1} \equiv 2/a^{2} = \text{const}\) is the scalar curvature of the internal space (two-sphere). The minimum of this potential defines an effective four-dimensional cosmological constant: \(\Lambda_{(4)\text{eff}} = U_{\text{eff}}(\beta = 0)\). We consider the case of flat external space-time. Therefore, the effective cosmological constant should be equal to zero:

\[ \Lambda_{(4)\text{eff}} = 0 \quad \Rightarrow \quad \frac{1}{\dot{R}_{1}} = \kappa \Lambda_{0} + \kappa \varepsilon_{c}. \quad (C5)\]

The comparison of this equation with the first one in \((5)\) shows that \(\varepsilon \equiv \varepsilon_{c}\). Therefore, the Eq. \((C5)\) is automatically satisfied for our model.

The extremum condition gives

\[ \frac{\partial U_{\text{eff}}}{\partial \beta} \bigg|_{\beta=0} = 0 \quad \Rightarrow \quad \frac{1}{\dot{R}_{1}} = (\omega_{1} + 1)\kappa \varepsilon_{c}. \quad (C6)\]

The positivity of \(\dot{R}_{1}\) and \(\varepsilon_{c}\) results in the condition \(\omega_{1} > -1\). From Eqs. \((C5)\) and \((C6)\) we get the fine tuning

\[ \Lambda_{0} = \omega_{1} \varepsilon_{c}. \quad (C7)\]

It can be easily verified that this condition follows also from Eqs. \((5)\) and \((7)\). Therefore, it is automatically satisfied for our model. To get the stabilization, the extremum should be a minimum:

\[ \frac{\partial^{2} U_{\text{eff}}}{\partial \beta^{2}} \bigg|_{\beta=0} = 4 \omega_{1} (\omega_{1} + 1) \kappa \varepsilon_{c} > 0, \quad (C8)\]
where we have used the condition \( \text{[C5]} \). It can be easily seen that the minimum takes place for \( \omega_1 > 0 \) which exactly coincides with the condition \( \text{[20]} \). Therefore, the case of dust \( \omega_1 = 0 \) (the \( \text{[17]} \) case) does not fit this condition because the effective potential is flat.

For example, in the case of the Freund-Rubin stable compactification (see, e.g., \([12, 14, 15]\)) with two-forms

\[
F_{ik} = \begin{cases} 
\sqrt{|g_2|} \varepsilon_{ik} f & \text{for } i, k = 4, 5 \\
0 & \text{otherwise}
\end{cases}
\]  
(C 9)

where \( |g_2| = |g_{44}g_{55}| = a^4 \sin^2 \xi \) is the determinant of the metrics on the sphere of the radius \( a \), and \( \varepsilon_{ik} \) is a totally antisymmetric Levi-Civita tensor with \( \varepsilon_{45} = -\varepsilon_{54} = 1 \), and \( f \) is a constant which we define below, the energy-momentum tensor is

\[
T_{ik} = \begin{cases} 
(f^2/(8\pi)) g_{ik} & \text{for } i, k = 0, ..., 3; \\
-(f^2/(8\pi)) g_{ik} & \text{for } i, k = 4, 5.
\end{cases}
\]  
(C 10)

The comparison of this expression with the background energy-momentum tensor \( \text{[3]} \) shows that the parameter of the equation of state in the internal space \( \omega_1 = 1 \). Then, it can be easily seen with the help of Eqs. \( \text{[7]}, \text{[C3]} \) and \( \text{[C7]} \) that we get the following fine tuning relations:

\[
\frac{f^2}{8\pi} = \Lambda_6 = \frac{1}{2\kappa a^2} = \bar{\varepsilon} = \varepsilon_c/a^4
\]  
(C 11)

with full agreement with the results of the paper \([12]\). Similarly, we can consider the stabilization by means of the Casimir effect where \( \omega_1 = 2 \) \([15]\).
