Investigation of antibiotic susceptibilities of *Brucella* Strains isolated from various clinical samples in eastern Turkey

Esra Gültekin¹*, Muhammet Hamidullah Uyanık², Ayşe Albayrak³ and Selçuk Kılıç⁴

**Abstract**

**Background:** Brucellosis is a worldwide zoonotic disease that causes serious public health problems. This study aimed to identify *Brucella* strains isolated from various clinical samples by conventional and molecular methods and to determine antimicrobial susceptibilities against doxycycline (DOX), streptomycin (STR), ciprofloxacin (CIP) and rifampicin (RIF) by the gradient strip (*E* test) test method.

**Methods:** A total of 87 *Brucella* strains isolated from various clinical specimens between 2004 and 2018 were included in this study. While four of the 87 strains included in the study were identified only at the genus level, the remaining 83 strains were identified at the species level by the Real-Time Multiplex PCR (M-RT-PCR) method and conventional methods were used for biotyping.

**Results:** According to molecular identification results, 83 strains were identified as *B. melitensis* by the M-RT-PCR method, with 82 strains identified as *Brucella melitensis* biovar (bv) 3 and one as *B. melitensis* bv 1 according to the conventional biotyping method. Among the antibiotics studied, CIP was found to be the most active agent according to the minimum inhibitory concentrations (MIC)⁹₀ values. This was followed by DOX and STR, respectively. While all of the isolates were sensitive to CIP, DOX and STR, 18 (20.7%) strains were found to be moderately susceptible to RIF, with the highest values of MIC⁵₀ and MIC⁹₀.

**Conclusions:** In our study, all strains were identified as *B. melitensis*. DOX, STR, CIP and RIF used in the treatment of brucellosis were found to be effective.

**Keywords:** Antimicrobial susceptibilities, Biotyping, *Brucella*, *E* test

---

**Background**

The *Brucella* species is a zoonotic infectious agent that can be transmitted to humans by direct contact with body secretions by impaired skin, inhalation and conjunctiva, as well as the consumption of meat, milk and milk products of animals, such as infected sheep, goats, cattle and pigs. Although human-to-human transmission is rare, it can also be transmitted through sex, blood transfusion and breast milk [1]. The incubation period of brucellosis, which is a systemic infectious disease, is 2–3 weeks. It begins with general signs of infection, progresses with septicemia and can be seen in different clinical forms effecting many organs [1, 2].

With the appropriate clinical manifestations, the diagnosis of the disease occurs by serological tests and the isolation of the agent [1, 3]. Although definitive diagnosis is isolation of bacteria from culture in brucellosis, serological methods are mostly preferred, due to the difficulties in isolating the agent most of the time, especially in chronic cases, the risk of laboratory infection, and the delayed results [4]. Although many serological methods...
can be used in the diagnosis of brucellosis, Rose Bengal Test (RBT) and Standard Tube Agglutination (STA) tests are the most widely preferred methods all over the world. Enzyme-Linked Immunosorbent Assay (ELISA) is a reliable serological method that can quickly detect specific immunoglobulins (IgG, IgM, IgA) used in the diagnosis of brucellosis with high sensitivity and specificity [5]. The isolation, identification and biotyping of the Brucella species are very important for both epidemiological studies and eradication programs. Information about the species and biotype distribution of Brucella is important as it will contribute to the follow-up of biotypes and vaccine strains in Turkey as well as the selection of optimal strains used in serological diagnosis [6].

The World Health Organization (WHO) recommends a combination of doxycycline (DOX) and rifampicin (RIF) for at least 6 weeks for the treatment of brucellosis. Alternatively, it recommends a combination of streptomycin (STR) for 2–3 weeks and DOX for 6 weeks [7]. Tetracyclines cannot be used in children younger than 8 years. For this reason, 6 weeks of trimethoprim/sulfamethoxazole (TMPSMZ) and 3 weeks of STR or 7–10 days of gentamicin may be used in children under the age of eight, and treatment protocols such as RIF and TMP/SMZ or RIF and an aminoglycoside for 6 weeks are recommended. Tetracyclines cannot be used in pregnancy, either. Fetal toxicity has been reported in pregnant women treated with STR. For this reason, TMP/SMZ during pregnancy and alternatively, at least 45 days of RIF are recommended. It is recommended to use DOX for 8 weeks or longer in the treatment of spondylitis, which is one of the complications of brucellosis, and adding RIF or TMP/SMZ, which crosses the blood–brain barrier well, to DOX-STR regimens for at least 6–8 weeks or longer in the treatment of neurobrucellosis. In the treatment of endocarditis, it is recommended to add RIF or co-trimoxazole to a combination of DOX and aminoglycoside for at least 8 weeks [1].

Although Brucella isolates are generally thought to be sensitive to antibiotics, there have been cases reported with antibiotic resistance and relapse. Resistance to drugs used in the treatment of brucellosis is a particularly important problem in low socioeconomic areas of developing countries, where tuberculosis is endemic. This problem raises concerns about developing drug resistance to long-term tuberculosis medications in brucellosis treatments [2]. Therefore, it is important to follow the sensitivity of antibiotics widely used in the treatments. This study aimed to identify the Brucella strains isolated from various clinical samples by conventional and molecular methods and to determine antibiotic susceptibilities against DOX, STR, ciprofloxacin (CIP) and RIF by the gradient strip (E test) method.

Methods
A total of 87 Brucella strains isolated from various clinical specimens at the Atatürk University Medical Faculty, Medical Microbiology Laboratory between 2004 and 2018 were included in this study. The samples included in the study were isolated from patients from Erzurum and 10 surrounding provinces in the east of Turkey. Brucella strains were isolated from blood (n = 84), bone marrow (n = 2) and cerebrospinal fluid (CSF) (n = 1).

The strains were identified at the species level using colony morphology, Gram staining, growth characteristics, oxidase, catalase, motility testing and polyvalent antisera agglutination methods. Strains previously isolated and identified as Brucella spp. were stored in 10% skimmed milk and maintained at −80 °C until conventional biotype, molecular typing and antibiotic susceptibility testing were performed. Strains were subcultured twice before beginning the study.

Biovar determination by conventional methods
For the identification of Brucella spp., conventional biotyping methods were used, including the CO₂ requirement, H₂S production, urease activity, sensitivity to thionin and basic fuchsin dyes (20 and 40 μg/ml), lysis by Tbilisi phage and agglutination with monospecific A and M antisera [8].

Molecular typing of Brucella species
The real-time multiplex PCR (M-RT-PCR) method was used for molecular identification at the genus and species levels. Identification of Brucella spp., B. melitensis and B. abortus was performed with this method, simultaneously. All of the strains included in the study were inoculated into Serum Dextrose Agar (SDA) medium, and the plates were incubated at 35 °C for 48 h in a 5% CO₂ atmosphere. To obtain bacterial DNA, the QIAamp® DNA Mini and Blood kit was used. Molecular identification of Brucella from the obtained bacteria, DNA IS711 element BME1162 (GenBank, NC003317) was used for B. melitensis; IS711 element (GenBank, AF148682) specific alkB gene was used for B. abortus; bcs3p1 gene (GenBank, NM20404) region was used for Brucella spp., and also TaqMan probe (TaqMan, Palo Alto, USA) were used. M-RT-PCR LightCycler® FastStart DNA Master HybProbe (Roche Diagnostics, Germany), 1.5 mM MgCl₂ (Roche Diagnostics, Germany), forward primer (3 nM) (Sigma-Genosys, USA), reverse primer (100 nM), each 16 μl multiplex PCR reaction mixtures containing 100 nM from a probe were prepared and 4 μl templates were added. Then, amplification was performed on the LightCycler 480 PCR (Roche Diagnostics, Germany). Amplification was performed on a totally 45 cycles with the following steps; after 10 min of denaturation at 95 °C
followed by 15 s at 95 °C and 1 min at 60 °C. The results were obtained using the LightCycler 96 assay program, which evaluates the presence or absence of logarithmic fluorescence signal increase at the wavelength appropriate for each probe. In each study, at least one positive and DNA-free negative control was used.

**Determination of antimicrobial susceptibility**

Minimum inhibitory concentrations (MIC) of DOX, STR, RIF and CIP were determined by the E test method (Biomerieux®, France). The E test strips were stored at −20 °C until the time of use. An inoculum was prepared in 0.5 McFarland turbidity in Muller–Hinton broth (Oxoid®) from each Brucella strain and applied with a sterile swab to Muller–Hinton agar plates and supplemented with 5% sheep blood. The E test strips were placed on the plate and incubated at 37 °C for 48 h [2]. The determination of MIC was evaluated according to the recommended reference ranges for Brucella species in the Guidelines for Clinical and Laboratory Standards (CLSI) for DOX and STR, and for the reference ranges recommended for slow-growing bacteria (Haemophilus) for RIF and CIP [9]. In each step of our study, B. melitensis biovar (bv) 1 (16 M), B. melitensis bv 3 (Ether), B. abortus bv 1 (NCTC10093), B. abortus bv 3 (Tulya), B. suis bv 1 (1330), E. coli ATCC 25922 and S. aureus ATCC 29213 were used for quality control. The lowest antibiotic concentration that inhibits the growth of bacteria was accepted as MIC. In addition, inhibition of 50% of the isolates as MIC50 and inhibition of the 90% of the isolates as MIC90 were accepted.

**Results**

The study included 87 Brucella strains isolated from different patients (30 female and 57 male). Samples had been sent from different clinical departments (Table 1).

According to the results of the M-RT-PCR method, 83 strains were identified as B. melitensis. The remaining 4 strains were identified only at the genus level and were detected as Brucella spp. According to the results of conventional biotyping, 82 of 83 strains were identified as B. melitensis bv 3 and one as B. melitensis bv 1. According to the results of the antibiotic susceptibility test performed by the E test method, all strains were susceptible to DOX, STR and CIP. Of the 87 isolates, 69 (79.3%) were sensitive to RIF and 18 (20.7%) were intermediate sensitive (MIC > 1 μg/ml). The antibiotic susceptibilities of Brucella strains are shown in Table 2.

According to MIC90 values, CIP was the most effective agent against Brucella strains, followed by DOX and STR. The highest MIC50 and MIC90 values were determined in RIF. The MIC ranges and MIC50 and MIC90 values of the various antimicrobial agents used against isolates in this study are given in Table 3.

**Table 1** Distribution of samples from clinical departments

| Clinical departments          | Samples |
|------------------------------|---------|
| Paediatrics                  | 33      |
| Infectious Diseases          | 23      |
| Internal Medicine            | 23      |
| Neurology                    | 2       |
| Anaesthesia and Reanimation  | 1       |
| Emergency                    | 1       |
| Obstetrics and Gynaecology   | 1       |
| Orthopaedics and Traumatology| 1       |
| Physical Medicine and Rehabilitation | 1 |
| General Surgery              | 1       |
| **Total**                    | **87**  |

**Table 2** Antibiotic susceptibility distribution of Brucella strains (μg/ml)

| Antibiotics | Sensitivity | Intermediate | Resistant | The limit of sensitivity |
|-------------|-------------|--------------|-----------|--------------------------|
| DOX         | 87          | –            | –         | ≤ 1                      |
| STR         | 87          | –            | –         | ≤ 8                      |
| RIF         | 69          | 18           | –         | ≤ 1*                     |
| CIP         | 87          | –            | –         | ≤ 1                      |

*RIF Intermediate resistance: 2, Resistance: ≥ 4

**Table 3** MIC ranges and MIC50 and MIC90 values of the various antimicrobial agents against Brucella species

| Antibiotics | Number of strains | MIC range μg/ml | MIC50 μg/ml | MIC90 μg/ml |
|-------------|-------------------|-----------------|-------------|-------------|
| DOX         | 87                | 0.016–1         | 0.047       | 0.19        |
| STR         | 87                | 0.064–0.75      | 0.19        | 0.5         |
| CIP         | 87                | 0.002–0.25      | 0.064       | 0.125       |
| RIF         | 87                | 0.008–2         | 1           | 1.5         |
All of the strains isolated in our study were also *B. melitensis*.

In Turkey, the most frequently isolated species is *B. melitensis*, and *B. abortus* is rarely seen. Among the most frequent *B. melitensis* strain, *B. melitensis* bv 3 was isolated, while bv 2 was not reported at all [4]. In the study conducted by Bodur et al. [17], 95.12% of the strains isolated were *B. melitensis* bv 3 and 4.88% were *B. melitensis* bv 1. In the study conducted by Denk et al. [10], 93.75% of the isolated strains were identified as *B. melitensis* bv 3 and 6.25% as *B. melitensis* bv 1.

In another study conducted by Çerkeç, all 187 strains suspected as *Brucella* species were identified as *B. melitensis* bv 3 [4]. Similarly, the most commonly isolated bv in our study was *B. melitensis* bv 3. Out of the 83 strains examined by conventional biotyping methods, 82 (98.79%) of them were identified as *B. melitensis* bv 3 and one strain was identified as *B. melitensis* bv 1.

The main problems encountered in brucellosis are treatment failure and relapse. Relapses usually occur in the first year after infection and, in most cases, the reasons are inadequate dosage, short-term treatment and inability of the patient to comply with treatment. In addition, the pharmacokinetics and immune status of the cells may play an important role in the development of relapses. The failure of treatment is often related to the pharmacokinetic and pharmacodynamics of antibiotics rather than resistance. Since the *Brucella* can survive in phagocytic cells, long-term combined therapy, as well as selective agents, must be able to penetrate both macrophages and remain active in the acidic environment [18]. Antimicrobials commonly used in the treatment of brucellosis are DOX, RIF, STR, (trimethoprim sulfamethoxazole) TMP/SMZ and quinolones [19, 20].

Antimicrobial susceptibility tests for *Brucella* strains, except for life-threatening conditions such as treatment failure, relapse, brucella meningitis and endocarditis, are generally not recommended in routine microbiology laboratory research as they require level 3 biosafety measures and are a high risk for laboratory workers [21]. In addition, there is no standardized antimicrobial susceptibility test for *Brucella* species established by the CLSI [2]. However, in 2006, the National Committee for Clinical Laboratory Standards (NCCLS) published a standardized method for determining the MIC values of potential bioterrorism agents. In this method, it was reported that TET/DOX, TMP/SMZ and STR can be studied by the microbroth dilution method for *Brucella*. [22]. However, in various studies, MIC values for RIF and CIP were determined based on the reference ranges recommended for slow growing bacteria (*Haemophilus*) in the CLSI guideline [2, 9, 14, 21, 23]. However, EUCAST’s breakpoint tables for interpretation of MICs and zone diameters do not contain any information regarding the breakpoint values related with the *Brucella* species [24]. In our study, the susceptibilities of *Brucella* species to various antimicrobials were evaluated by CLSI criteria [9].

Apart from the microbroth dilution method, agar dilution and *E* test methods are also used to determine MIC values. The disc diffusion method is not recommended for antimicrobial susceptibility testing [25]. In our study, the *E* test method, which is reliable, repeatable, practical and also requires less labour and time than other tests, was used [2, 21].

TET are the most effective and preferred agents for the treatment of brucellosis and are recommended for most treatment combinations, except in some special cases [10]. DOX is the most widely used TET derivative due to its ability to be administered once or twice a day, superior pharmacokinetic properties and less gastrointestinal side effects than TET [1, 16]. In various studies in different countries, MIC<sub>90</sub> values of DOX against *Brucella* species were found to be 0.25 μg/ml [3, 14, 23]. On the other hand, this value was considered quite high for MIC<sub>90</sub>: 32 in a study in China [26]. Some studies in Turkey found DOX to be the most active agent against *Brucella* strains according to the MIC<sub>90</sub> value [10, 16, 17]. Unlike these studies, Etiz et al. reported that DOX was not as effective as TMP/SXT according to MIC values [2]. In our study, DOX was the most active agent after CIP against *Brucella* strains according to the MIC<sub>90</sub> value.

STR is known as one of the most active agents in the treatment of brucellosis. Although side effects, such as ototoxicity and nephrotoxicity, limit its wide and parental use, it is preferred for the good results in bone- joint involvement [16]. In work carried out by Altun et al. [27], considerably higher MIC values of STR (0.125 to 256 μg/ml) and 8.3% of strains was resistant to STR. However, in many studies, MIC ranges (0.064–8 μg/ml) are still within the sensitivity range [2, 3, 14, 16, 18, 20, 23, 28–30]. In our study, the MIC range was 0.064–0.75 μg/ml and was consistent with the previous studies. According to the results of these studies, it can be seen that the antimicrobial agent can be used safely in terms of failures caused by resistance problems.

CIP is an important alternative in the treatment of brucellosis because of its excellent oral bioavailability and that it reaches high concentrations in phagocytic cells [23]. In the study conducted by Yamaç et al. [19], although high MIC values were determined for CIP, low MIC values were reported in many other studies [2, 11, 23, 28, 29, 31, 32]. Kılıç et al. [18] reported that CIP showed good activity when compared to TET and Ayaşlıoğlu et al. [30] reported that it was as effective as TET. In their study, Bodur et al. [17] determined
that CIP was the most active agent after DOX according to the value of MIC90. In our study, CIP was found to be the most active agent according to the MIC90 value. However, CIP is not recommended in monotherapy due to the lack of bactericidal activity at intracellular acidic pH, high recurrence rates and the risk of developing resistance to all fluoroquinolones in the community [23, 30, 32].

RIF is a potent antibiotic for the treatment of brucellosis. It has been widely accepted as the first choice in treating brucellosis. Several studies have reported that RIF has excellent activity against Brucella species, a good intracellular penetration and a significant synergism with combination treatments [16, 21]. Intermediate resistance rate to RIF changed between 2.1% and 75% of Brucella strains in Turkey [2, 12, 18, 20, 21, 30, 31]. In our study, 20.7% of the Brucella strains had intermediate resistance to RIF. However, in Turkey Etiz et al. [2] and Kaya et al. [20] found resistance to RIF by Brucella strains to be 2.00% and 2.94%, respectively.

In the study conducted by Abdel-maxoud [14] in Egypt, possible resistance to RIF was detected in 19% of the strains, while the study by Deshmukh [23] in Qatar found a higher resistance rate of 48%. There is potential for Brucella strains to resist RIF. The use of RIF as a long-term antitubercular agent in the treatment of tuberculosis simultaneously with brucellosis in many regions of the world may lead to the emergence of moderately susceptible and resistant Brucella strains. At the same time, the extensive use of RIF in the treatment of brucellosis may cause resistance to M. tuberculosis [2, 16].
