ABSTRACT

BACKGROUND AND PURPOSE: Recently, numerous investigational studies, case series, and case reports have been published describing various MR imaging brain findings in patients with COVID-19. The purpose of this literature review was to compile and analyze brain MR imaging findings in patients with COVID-19-related illness.

MATERIALS AND METHODS: Literature searches of PubMed, publicly available Internet search engines, and medical journal Web sites were performed to identify articles published before May 30, 2020 that described MR imaging brain findings in patients with COVID-19.

RESULTS: Twenty-two articles were included in the analysis: 5 investigational studies, 6 case series, and 11 case reports, encompassing MR imaging of the brain in 126 patients. The articles originated from 7 different countries and were published in 14 medical journals. MR imaging brain findings included specific diagnoses (such as acute infarct, posterior reversible encephalopathy syndrome) or specific imaging features (such as cortical FLAIR signal abnormality, microhemorrhages).

CONCLUSIONS: The most frequent diagnoses made on brain MR imaging in patients with COVID-19 were acute and subacute infarcts. Other common findings included a constellation of leukoencephalopathy and microhemorrhages, leptomeningeal contrast enhancement, and cortical FLAIR signal abnormality.

ABBREVIATIONS: COVID-19 = coronavirus disease 2019; PRES = posterior reversible encephalopathy syndrome; SARS-CoV-2 = Severe Acute Respiratory Syndrome coronavirus 2

Growing evidence suggests that coronavirus disease 2019 (COVID-19), secondary to infection with Severe Acute Respiratory Syndrome coronavirus 2 can manifest with a multitude of neurologic conditions including ataxia, seizure, acute stroke, and impaired consciousness.1,2 Since the World Health Organization declared coronavirus disease 2019 (COVID-19) a global pandemic on March 11, 2020,3 the medical literature describing COVID-19 mechanisms, manifestations, and treatments has expanded with extraordinary speed. In concordance with the World Health Organization’s efforts for rapid distribution of data by biomedical journals during public health emergencies,4 this rapid pace has been aided by the expedited peer-review processes instituted by multiple medical journals.5 Consequently, journals representing multiple disciplines simultaneously have published numerous articles describing imaging findings in COVID-19 illness. While pulmonary disease is the best recognized morbidity associated with COVID-19, there are many reported neurologic manifestations of this infection. The purpose of this literature review was to collect, analyze, and summarize the findings on brain MR imaging reported to date in patients with COVID-19.

MATERIALS AND METHODS

Due to the rapid pace of COVID-19-related publications, many relevant articles were not yet represented on the public data bases, including PubMed, and a standard systematic review was not possible. We, therefore, adopted an ad hoc approach that included queries of PubMed, other publicly available Internet search engines (such as Google, Google Scholar, and Bing), as well as a review of journal Web sites. Our review includes only articles published before May 30, 2020. Search terms included “brain MR imaging,”...
COVID-19 is associated with acute cerebrovascular disease, including intracranial hemorrhage, large-vessel occlusion, acute ischemic stroke, and dural venous sinus thrombosis.11-13 The apparent association of COVID-19 with cerebrovascular disease may reflect an increased risk of vessel thrombosis secondary to endothelial dysfunction, inflammation, platelet activation, and stasis.14 However, the exact pathophysiology of stroke in COVID-19 remains poorly understood. For example, it is presently unknown to what extent arterial thrombosis in COVID-19 is associated with pre-
existing atheromatous plaque versus an entirely de novo phenomenon. It is also unclear whether thrombosis predominantly occurs in large or small arteries and, to what extent, if any, nonthrombotic vascular stenosis may contribute to the incidence of infarction.

Other commonly described findings were diffuse white matter abnormality, consistent with leukoencephalopathy, in association with parenchymal microhemorrhages. As suggested by Radmanesh et al, COVID-19 may be associated with a form of leukoencephalopathy that is particularly characterized by the presence of microhemorrhage. This could be the direct consequence of SARS-CoV-2 CNS infection or a secondary effect of a generalized COVID-19 phenomenon (such as hypercoagulability). In addition, as postulated by Radmanesh et al, it may be a late complication of critically ill patients with COVID-19 secondary to hypoxia and possibly a manifestation of delayed posthypoxic leukoencephalopathy. Of note, all patients described by Radmanesh et al and most studied by Kandemirli et al were intubated. Furthermore, the cohort studied by Radmanesh et al was mechanically ventilated for a mean duration of 27 days. In their study, Radmanesh et al observed mild restricted diffusion within white matter regions of T2 hyperintensities, the same imaging characteristics seen with delayed posthypoxic leukoencephalopathy. 

Nicholson et al observed multifocal, predominantly petechial hemorrhages in patients with COVID-19 and speculated that they may have resulted from diffuse thrombotic microangiopathy, which has previously been reported to cause similar abnormalities and can lead to PRES. Several studies have recently described cytokine storms in COVID-19 infection, with resultant vascular endothelial damage, which can result in thrombotic microangiopathy. Nicholson et al further suggested that extracorporeal membrane oxygenation therapy may contribute to parenchymal brain abnormalities in COVID-19 due to obligatory anticoagulation with resultant hemorrhage. However, Radmanesh et al described extensive microhemorrhage in a cohort that did not receive extracorporeal membrane oxygenation.

Other brain MR imaging findings in patients with COVID-19 were leptomeningeal contrast enhancement and cortical FLAIR signal abnormality, either separately or in combination. Leptomeningeal contrast enhancement is a known manifestation of leptomeningitis and has been seen in other viral illnesses such as H1N1-associated encephalitis. Cortical FLAIR signal abnormality has a broad differential diagnosis and can include encephalitis, postictal state, PRES, as well as acute ischemia.

Despite the global reach of the pandemic and the vast number of critically ill patients, the small number of reported cases with brain MR imaging abnormalities is likely due to stringent policies on the use of MR imaging in patients with COVID-19. The American College of Radiology recently issued recommendations for practitioners to minimize the use of MR imaging in patients infected or suspected of having COVID-19 infection unless absolutely necessary. Similar policies are likely to be in effect worldwide, limiting MR imaging use to patients with COVID-19 with the highest clinical urgency. This policy may, at least in part, explain most of the patients in the published reports being severely ill, many of them mechanically ventilated. It would be necessary to perform brain MR imaging examinations in symptomatic patients with COVID-19 with mild and moderate illness to determine the full spectrum of central nervous system involvement in this disease.

In addition to the small number of reported cases, our study is necessarily limited by data accessibility. Our searches of the main on-line data bases missed a substantial portion of existing COVID-19-related reports. Therefore, we added manual

![Acute infarcts and microhemorrhages. Axial diffusion (A and B) and gradient-echo (C and D) sequences in a 61-year-old man with COVID-19 infection. There are acute infarcts within the bilateral cerebral white matter (blue arrows) and a left occipital hemorrhagic infarct (orange arrow). There are innumerable microhemorrhages throughout the bilateral cerebral hemispheres (yellow arrows).](https://www.ajnr.org/article/S0895-6111(20)34587-8/fulltext)
searches of multiple journal Web sites. As a result, our search results are likely not reproducible. Articles were often identified ahead of publication and before assignment of a PubMed number. Consequently, some relevant articles may have been missed.

CONCLUSIONS
In this descriptive literature review, the most frequent diagnoses made at brain MR imaging in patients with COVID-19 were acute and subacute infarcts. Other common findings included a constellation of leukoencephalopathy and microhemorrhages, leptomeningeal contrast enhancement, and cortical FLAIR signal abnormality. Because these results are preliminary, a formalized systematic review following the Preferred Reporting Items for Systematic Reviews and Meta-Analyses guidelines will be needed as more articles are published.
