Determinants of Economic Growth across the European Union: A Panel Data Analysis on Small and Medium Enterprises

Larissa M. Batrancea

Department of Business, Babeş-Bolyai University, 7 Horea Street, 400174 Cluj-Napoca, Romania; larissa.batrancea@ubbcluj.ro

Abstract: Across the European Union, small and medium enterprises (SMEs) are major contributors to the increase of the regional gross domestic product. The present study investigates the relationship between economic growth, imports and exports regarding the activity of small and medium enterprises within the European Union (EU-28). A panel generalized method of moments (GMM) analysis and a panel two-stage least squares (2SLS) analysis were carried out for the period 2005–2020. Empirical results indicated that online imports and exports together with extra-EU imports and exports had a significant impact on economic growth, proxied by value added, venture capital investments and turnover from e-commerce. In the light of these results, regional and national authorities are called to support business endeavors of small and medium enterprises due to their relevance on the market and contribution to the financing of national budgets.

Keywords: small and medium enterprises; exports; imports; trade; EU-28; economic growth

1. Introduction

Within nowadays global market, the level of economic growth has constantly been an important matter on the agenda of national authorities, regional unions and international bodies [1–4]. A sensible reason for this fact is that studies show a strong bidirectional relationship between economic growth and human development [5–7]. On the one hand, economic growth enhances human development levels because it offers citizens more resources to support their needs, improve living conditions and overall wellbeing. At the same time, government authorities can amass more financial resources through taxation in order to improve the quality of public goods and services. On the other hand, societies that increase their level of human development (e.g., life expectancy and health status, access to education, living standards) equip citizens with a wide range of capabilities that can thrive via economic activities. In addition, the question of economic growth is intensively discussed within the context of sustainable development and the need for a judicious use of global resources of future generations [8–10].

The former US governor for the state of Tennessee, Phil Bredesen, used to state the following about economic growth: “Continuing economic growth requires both recruitment of new companies and expansion of existing businesses”. Indeed, national and regional economies around the world thrive based on the creation and development of various types of businesses that interact with one another, among which small and medium enterprises (SMEs) play a significant role [11–15].

The World Bank provides relevant insights on the importance of SMEs for the world economy. Hence, SMEs are credited for representing around 90% of global businesses and for employing around 50% of the global workforce. In emerging countries, these businesses generate 40% of the gross domestic product (GDP) [16].

Across the European Union, small and medium-sized enterprises (SMEs) account for 99% of all business activities, they are considered “the backbone” of the regional economy since they generate 58% of the GDP and employ 67% of the workforce in the private
sector [17]. Among the most notable characteristics of the European SMEs are the following: focus on innovation; quick adaptability to market demands; strong impact in all economic sectors; young and qualified employees. In terms of financial upper hands, European SMEs benefit from “above-average equity capital and a wide spread of investment risks” [17].

With respect to business initiative, drive and innovation, member states in the European Union host eight of the first 30 start-up ecosystems worldwide. For that matter, countries such as Cyprus, Estonia, Lithuania, Latvia and Malta have registered the highest start-up intensity levels across all EU members.

Table 1 [18] (p. 11) offers details on the criteria that are used by the European Commission to categorize small and medium enterprises: (a) headcount annual work unit (i.e., number of employees); (b) annual turnover or annual balance sheet total (i.e., overall value of the items listed in this financial statement). These criteria were enacted via the EU recommendation 2003/361 and they are applied in the case of individual firms.

| Enterprise Category | Headcount Annual Work Unit | Annual Turnover | Annual Balance Sheet Total |
|---------------------|----------------------------|-----------------|---------------------------|
| Medium-size company | <250                       | ≤€50 million    | ≤€43 million              |
| Small company       | <50                        | ≤€10 million    | ≤€10 million              |
| Micro-company       | <10                        | ≤€2 million     | ≤€2 million               |

According to the European Commission, the abovementioned criteria are fundamental because companies labeled as small and medium enterprises often enjoy various benefits, among which: financial support from the EU budget via multiple programs targeting only SMEs (i.e., competitiveness, innovation, research); less red tape or lower administrative compliance fees [18]. At the same time, besides the aforementioned benefits, the development of SMEs in general and European SMEs in particular may be hindered by various constraints regarding resources or information available. Nevertheless, such constraints can be overcome by fostering trade relationships (including exports) and “inter-firm collaborations” [19]. For that matter, due to extensive internet facilities, businesses such as SMEs have increased their presence on international markets via exporting activities [20].

In this context of the SMEs’ substantial impact on the economy of the European Union, the present study investigates the relationship between economic growth (proxied by value added rate, venture capital investments rate, turnover from e-commerce rate) and various indicators related to import and export activities of SMEs across the 28 member states of the European Union during almost two decades (i.e., 2005–2020). The focus on import and export activities stems from the fact that, as constantly reported in the mainstream literature even from early on until nowadays, rising exports stimulate aggregate economic growth [21–25].

The set of independent variables included the following: intra-EU exports and imports of goods; intra-EU online importers; extra-EU online exporters; extra-EU exports and imports of goods. Variables were retrieved from Comext, Eurostat, Structural Business Statistics and World Bank databases.

The remainder of the paper is the following. Section 2 gives a brief account on the determinants of economic growth, exports and imports. Section 3 presents the sample and period of analysis, variables of interest, general format of the econometric model, methodology and research hypotheses. Section 4 delves into all types of analyses, from descriptive statistics and correlations to panel data modelling. The last section summarizes and discusses the main results, emphasizes policy implications of research outcomes and sketches future research directions.
2. Literature Review

An increasing body of literature focuses on the role of small and medium enterprises in the process of economic growth [26–30]. In this sense, Wozniak et al. [31] assess the connection between the GDP structure and the development level of Polish small and medium enterprises in the period 1996–2016. Focused on the same national economy dominated by the economic activities of SMEs, Czarniewski [32] stresses the fact that these economic entities play a fundamental role in the advancement of innovation and entrepreneurship within a country.

By means of a survey study conducted on observations from 54 French SMEs and 30 British SMEs, Ben Abdelaziz, Alaya and Dey [33] target the matter of sustainability regarding their economic activities. The authors advance insights on how operations run by SMEs can become more sustainable via the implementation of sustainable inputs and outputs.

Kazmi and Naaranoja [34] investigate the impact of an educational program designed for new entrepreneurs in Finland, which aimed to ease business transfer process, to fuel business growth and to ensure business survival on the market. Survey data confirmed the effectiveness of such training programs, especially in the case of SMEs dealing with scarce resources.

Vishnupriya and Abirami [35] focus on SMEs since these types of businesses represent the backbone of the Indian economy and mainly generate increases in the national GDP. More specifically, authors scrutinize the factors that hinder SMEs growth in India and propose sensible solutions to overcome such challenges.

In the same line of thought, Gao [36] studies SMEs within the context of the Chinese market because SMEs represent about 99% of the total number of businesses operating in China. The author notes that, besides their fundamental contribution to the country GDP, SMEs stand out as the most innovative business endeavors on the national market. The research study provides insights on efficient ways of dealing with financial difficulties that SMEs encounter.

Nizaeva and Coskun [37] examine the factors that influence the access to financing of SMEs across emerging economies in the Western Balkan region. Namely, authors take into account the following independent variables: concentration of banking sector; credit information; firm size; firm age; GDP per capita; ownership type; property registration costs; transparency of accounting data. According to empirical results, firm size, firm age and the concentration of the banking sector register significant influences on SMEs capacity of obtaining financial resources.

By means of a panel data analysis, Jenkins and Hossein [38] investigate the impact of macroeconomic variables such as GDP growth rate, competition, inflation rate and government domestic borrowing on SMEs access to commercial bank lending. The sample included data from emerging economies such as Argentina, Brazil, Chile, Mexico, Poland and Turkey. Empirical results show that high levels of GDP grow rate, intense competition, lower levels of inflation rate and less public borrowings can stimulate credit institutions to grant financial resources to SMEs.

The present study fills the literature gap concerning the contribution of SMEs activities across EU member states to the level of economic growth proxied by variables such as value added rate, venture capital investments rate, turnover from e-commerce rate.

3. Materials and Method

The following paragraphs will detail on the sample, variables of interest, methodology, general form of the econometric model and research hypotheses used in the present study.

The chosen period of analysis spanned 16 years, namely from 2005–2020. The sample included small and medium enterprises (SMEs)-related data from the 28 countries that belonged to the European Union (EU-28) during this period: Austria, Belgium, Bulgaria, Croatia, Cyprus, Czech Republic, Denmark, Finland, France, Germany, Greece, Estonia,
Hungary, Ireland, Italy, Latvia, Lithuania, Luxembourg, Malta, Netherlands, Poland, Portugal, Romania, Slovakia, Slovenia, Spain, Sweden, United Kingdom.

From a methodological standpoint, the study favored multiple methods of analysis, starting from the standard descriptive statistics and correlation analysis up to an econometric approach via panel data modelling (i.e., generalized methods of moments; two-stage least squares with cross-section weights). The EViews statistical software version 10.0 was the workhorse during the analysis process.

Analyses were conducted with the variables of interest below:

Value added rate (VAD_RATE) measures the variation of the value added of goods and services produced in a national economy. This variable was used as a proxy for the level of economic growth, it is measured in percentage points and it was retrieved from the World Bank database.

Venture capital investments rate (VENTURE) as a percentage of GDP represents a part of private equity that needs to be invested in companies not publicly listed, which develop new products and technologies. This type of investment is used to support early-stage business endeavors (i.e., seed, start-up) or expansions (i.e., “later stage venture”). The variable was retrieved from the Eurostat database and it was used as a proxy for the level of economic growth.

Turnover from e-commerce rate (TURNOVER) includes the overall turnover from all manufacturing and service sectors, excluding the financial sector. The variable was retrieved from the Eurostat database, namely the Community survey on ICT usage and eCommerce in enterprises. It was used as a proxy for the level of economic growth.

Intra-EU exports of goods by SMEs in industry (EUEXP) measures the percentage of SMEs that exported goods within the EU member states. The variable was retrieved from the Eurostat database.

Intra-EU imports of goods by SMEs in industry (EUIMP) measures the percentage of SMEs that imported goods from the EU member states. The variable was retrieved from the Eurostat database.

Intra-EU online importers (EUIMPOL) measures the percentage of SMEs that imported goods online from the EU member states. This variable took into consideration only SMEs with 10 or more employees, which made online acquisitions from suppliers operating in other EU countries. Micro-companies were not considered. The variable was retrieved from the Eurostat database.

Extra-EU online exporters (EUEXTRAOL) measures the percentage of SMEs that exported goods online in other EU member states. This variable took into consideration only SMEs with 10 or more employees, which made online acquisitions from suppliers operating in other EU countries. Micro-companies were not considered. The variable was retrieved from the Eurostat database.

Extra-EU exports of goods by SMEs in industry (EXTRAEXP) indicates the percentage of SMEs that exported goods outside the European Union. This time, micro-companies were included. In order to compute the variable, the number of exporting SMEs (in the nominator) was retrieved from the Comext database, while the total number of SMEs (in the denominator) was retrieved from the Structural Business Statistics database.

Extra-EU imports of goods by SMEs in industry (EXTRAIMP) measures the percentage of SMEs that imported goods from countries outside the European Union. As before, micro-companies were included. In order to compute the variable, the number of exporting SMEs (in the nominator) was retrieved from the Comext database, while the total number of SMEs (in the denominator) was retrieved from the Structural Business Statistics database.

Figure 1 shows considerable decreases in the value added rate variable for Austria (2020), Belgium (2019), Bulgaria (2018), Cyprus (2016), Denmark (2015), Greece (2009), Hungary (2008), Ireland (2017), Latvia (2008, 2020), Portugal (2014) and Romania (2013), after the 2008 global financial crisis and the European sovereign debt crisis. During the first year of the pandemic crisis, all EU member states have registered mitigations in this indicator, except for Slovakia, which reported a VAD_RATE of 9.53%.
Figure 1. The evolution of VAD_RATE across EU-28 in the period 2005–2020.

Figure 2 displays substantial increases of the VENTURE variable for Denmark (2015), Luxembourg (2018), Netherlands (2018), Sweden (2009) and the United Kingdom (2010), following the 2008 global financial crisis and the European sovereign debt crisis. During the first year of the current pandemic crisis, only Austria (1.43%) and Belgium (4.25%) have reported increases with respect to this variable.

Figure 2. The evolution of VENTURE across EU-28 in the period 2005–2020.

Figure 3 shows the ascending trend of the TURNOVER variable for Belgium (2019), Cyprus (2015), Czech Republic (2015), Denmark (2014), Finland (2012), Hungary (2007), Portugal (2014) and Sweden (2009) after the 2008 global financial crisis and the European

first year of the pandemic crisis, all EU member states have registered mitigations in this indicator, except for Slovakia, which reported a VAD_RATE of 9.53%.

Figure 1. The evolution of VAD_RATE across EU-28 in the period 2005–2020.

Figure 2 displays substantial increases of the VENTURE variable for Denmark (2015), Luxembourg (2018), Netherlands (2018), Sweden (2009) and the United Kingdom (2010), following the 2008 global financial crisis and the European sovereign debt crisis. During the first year of the current pandemic crisis, only Austria (1.43%) and Belgium (4.25%) have reported increases with respect to this variable.

Figure 2. The evolution of VENTURE across EU-28 in the period 2005–2020.

Figure 3 shows the ascending trend of the TURNOVER variable for Belgium (2019), Cyprus (2015), Czech Republic (2015), Denmark (2014), Finland (2012), Hungary (2007), Portugal (2014) and Sweden (2009) after the 2008 global financial crisis and the European
sovereign debt crisis. In terms of the current pandemic crisis, all EU member states have registered lower values: Austria (9.31%), Belgium (14.09%), Bulgaria (2.20%), Croatia (9.02%), Cyprus (7.80%), Denmark (17.55%), to name but a few.

![Figure 3](image-url)

**Figure 3.** The evolution of TURNOVER across EU-28 in the period 2005–2020.

Figure 4 shows the evolution of intra-EU exports and imports. According to the analysis, the intra-EU imports have exceeded by far the intra-EU exports across the entire period. Nevertheless, intra-EU exports of SMEs from Cyprus, Sweden and the United Kingdom have exceeded the intra-EU imports.

![Figure 4](image-url)

**Figure 4.** The evolution of intra-EU exports (in red) and intra-EU imports (in blue) across EU-28 in the period 2005–2020.

Figure 5 displays that extra-EU exports have registered higher levels than extra-EU imports in countries such as Croatia, France, Germany, Latvia, Poland, Portugal, Romania, Spain and the United Kingdom.
Figure 5 displays that extra-EU exports (in red), extra-EU imports (in blue) and extra-EU online exports (in green) across EU-28 in the period 2005–2020.

Overall, when SMEs reported more exports than imports, they generated an additional value within the EU, which triggered an increase in VAD_RATE. At the same time, more exports generated an increase in VENTURE and TURNOVER, which triggered positive consequences for the life standards of EU citizens. In this sense, SMEs could be regarded as a driving force of EU development level.

The general form of the econometric model was the following:

\[ Y_{mt} = a_0 + a_1 X_{1mt} + a_2 X_{2mt} + a_3 X_{3mt} + a_4 X_{4mt} + a_5 X_{5mt} + \delta_m + \theta_t + \varepsilon_{mt} \]  

(1)

where,

- \( a_0 \) represents the intercept;
- \( a_i \) represents the coefficient of the predictors;
- \( X \) represents the predictors;
- \( m \) represents the activity of the SMEs from the EU-28 country sample;
- \( t \) represents the years included in the analysis, spanning from 2005 to 2020;
- \( \delta_m \) represents the time-invariant country specific fixed effects;
- \( \theta_t \) represents the fixed effects controlling for financial crises;
- \( \varepsilon_{mt} \) represents the error term.

In order to run panel data modelling via panel generalized method of moments (GMM) and two-stage least squares (2SLS) panel, one had to opt between fixed and random effects. In this sense, the Hausman test was used because it disentangles between the two types of effects. According to its null hypothesis, there are no differences between fixed and random effects, therefore random effects should be included in the econometric models. According to the alternative hypothesis, fixed effects should be incorporated into the models.

The choice of estimating results using both GMM and 2SLS is grounded on numerous studies reported in the literature [39–46], which recommend these methods for ruling out endogeneity concerns. Hence, by means of approaches such as GMM and 2SLS, one gains confidence in the strength and accuracy of the estimated results.

The empirical study investigated the following research hypotheses:

**Hypothesis 1 (H1).** There is a significant relationship between VAD_RATE and intra-EU imports, intra-EU online imports, extra-EU online exports, extra-EU imports, extra-EU exports.
Hypothesis 2 (H2). There is a significant relationship between VAD_RATE and intra-EU exports, intra-EU online imports, extra-EU imports, extra-EU exports.

Hypothesis 3 (H3). There is a significant relationship between VENTURE and intra-EU imports, intra-EU online imports, extra-EU online exports, extra-EU imports, extra-EU exports.

Hypothesis 4 (H4). There is a significant relationship between VENTURE and intra-EU exports, intra-EU online imports, extra-EU online exports, extra-EU imports, extra-EU exports.

Hypothesis 5 (H5). There is a significant relationship between TURNOVER and intra-EU imports, intra-EU online imports, extra-EU online exports, extra-EU imports, extra-EU exports.

Hypothesis 6 (H6). There is a significant relationship between TURNOVER and intra-EU exports, intra-EU online imports, extra-EU online exports, extra-EU imports, extra-EU exports.

The research hypotheses will be tested via panel data modelling in the subsequent section.

4. Results

4.1. Descriptive Statistics

As a first step of the analysis approach, measures of central tendency and variation (i.e., mean, median, standard deviation, minimum and maximum values) were computed together with the metrics that are generally used to characterize distributions (i.e., skewness, kurtosis). Namely, descriptive statistics for all variables of interest were determined: value added rate; venture capital investments rate; turnover from e-commerce rate; intra-EU exports of goods by SMEs in industry; intra-EU imports of goods by SMEs in industry; intra-EU online importers; extra-EU online exporters; extra-EU exports of goods by SMEs in industry; extra-EU imports of goods by SMEs in industry.

Table 2 displays the measures of central tendency, variation and distribution characteristics for the EU-28 sample.

| VAD_RATE | VENTURE | TURNOVER | EUIMP | EUEXP | EUIMPOL | EUEXTRAOL | EXTRAEXP | EXTRAIMP |
|----------|---------|----------|-------|-------|---------|-----------|----------|----------|
| Mean     | 1.9551  | 0.0274   | 8.5385| 16.8722| 13.2104 | 3.9475    | 11.2158  | 9.5874   |
| Median   | 2.1335  | 0.0178   | 8.0238| 15.7543| 10.5625 | 3.5027    | 11.2592  | 9.3459   |
| Maximum  | 43.5552 | 0.2034   | 28.9837| 46.8394| 39.9088 | 12.4841   | 26.7166  | 22.7476  |
| Minimum  | -11.7670| 0.0000   | 0.0101| 2.2174 | 2.4649 | 1.1112    | 0.2344   | 2.0172   |
| Std. dev. | 4.0599  | 0.0332   | 5.1065| 16.5321| 9.3226 | 8.5287    | 2.4198   | 5.2970   |
| Skewness | 1.9885  | 2.4371   | 0.6287| 1.3046 | 0.6639 | 1.1129    | 1.0551   | 0.4225   |
| Kurtosis | 28.8316 | 11.1868  | 3.2176| 5.4059 | 3.2196 | 3.9883    | 4.4903   | 2.8869   |

As can be noticed starting from the standard deviation values, the variables EUIMP and EUEXP registered the largest volatility, while VENTURE registered the smallest volatility. According to the skewness values, all variables were skewed to the right. Since the kurtosis values for the variables VAD_RATE, VENTURE, TURNOVER, EUIMP, EUEXP, EUIMPOL and EUEXTRAOL were above the threshold of 3, it means that their distributions were leptokurtic. At the same time, EXTRAEXP and EXTRAIMP had platykurtic distributions because the kurtosis values corresponding to them were below 3.

For the purpose of investigating the normal distribution of empirical data, the standard Jarque-Bera test was used. Under the null hypothesis of this test, data are normally distributed when the corresponding probability exceeds the chosen significance level. If the null hypothesis is rejected, it indicates that data are non-normally distributed. In the case
of this study, the Jarque-Bera test showed that all variables of interest were non-normally distributed at the 1% level.

4.2. Correlation Analysis

As a second step of the analysis approach, correlations were determined. When modelling panel data, correlation analysis serves to spot potential multicollinearity problems that could bias estimated results. Such multicollinearity issues become problematic when correlation coefficients exceed the 0.9 threshold.

Table 3 illustrates the correlation coefficients for the variables of interest.

| VAD_RATE | TURNOVER | VENTURE | EUEXP | EUEXTRAOL | EUIMP | EUIMPOL | EXTRAEXP | EXTRAIMP |
|----------|----------|---------|-------|-----------|-------|---------|----------|----------|
| VAD_RATE | 1        |         |       |           |       |         |          |          |
| TURNOVER | -0.076   | 1       |       |           |       |         |          |          |
| VENTURE  | -0.013   | 0.202 * | 1     |           |       |         |          |          |
| EUEXP    | -0.090   | 0.042   | 0.439 * | 1       |       |         |          |          |
| EUEXTRAOL| -0.022   | 0.469 * | 0.203 * | 0.079   | 1     |         |          |          |
| EUIMP    | -0.075   | 0.083   | 0.417 * | 0.866 ***| 0.127 | 1       |          |          |
| EUIMPOL  | -0.042   | 0.306 * | 0.379 * | 0.366 * | 0.459 | 0.579 **| 1        |          |
| EXTRAEXP | -0.048   | 0.145 * | 0.574 **| 0.626 **| 0.332 | 0.632 **| 0.580 **| 1        |
| EXTRAIMP | -0.142 * | 0.168 * | 0.499 * | 0.622 **| 0.269 | 0.494 * | 0.446 *  | 0.809 ***|

Note: ***, **, * indicate significance at the 1%, 5% and 10% levels.

Correlation analyses presented in Table 3 indicated that all significant associations between independent variables were positive. In this context, the highest correlation was established between the intra-EU exports of goods (EUEXP) and intra-EU imports of goods (EUIMP) ($r = 0.87$). The lowest correlation was established between extra-EU online exports (EUEXTRAOL) and extra-EU exports (EXTRAEXP) ($r = 0.33$).

Because none of the correlation coefficients exceeded the threshold of 0.9, it could be concluded that the risk of multicollinearity was low and it would not bias the estimated results. Multicollinearity will also be checked with the variance inflation factor (VIF).

4.3. Panel Data Modelling

Table 4 displays the estimated coefficients of the independent variables for all econometric models. The outcome variables were VAD_RATE, VENTURE and TURNOVER.

With respect to Model 1, when examining the evolution of the value added rate via panel generalized method of moments (GMM) at first-difference estimation, results showed that the majority of independent variables had significant influence on VAD_RATE. Namely, should EUIMP and EXTRAEXP increase by one percent, VAD_RATE would rise by 0.03 percentage points and by 1.96 percentage points, respectively. At the same time, when EUEXTRAOL and EXTRAIMP augmented by one percent, VAD_RATE would decrease considerably by 0.15 percentage points and 3.68 percentage points, respectively. Overall, the probabilities corresponding to the $J$-statistic test ($J = 23.95$, $p = 0.30$) and the Arellano-Bond test for AR(2) ($p = 0.69$) indicated that the combined effect of the independent variables was statistically significant.

When the model estimated VAD_RATE via 2SLS panel (with cross-section random effects), the impact of the EXTRAIMP and EXTRAEXP was not significant ($F = 1.84$, $p = 0.104$).

Hence, the first research hypothesis was confirmed by the econometric modelling focused on value added rate.
Table 4. Econometric models regarding the activity of SMEs across the EU-28 countries with respect to value added rate.

| Method       | VIF  | GMM | 2SLS | VIF  | GMM | 2SLS |
|--------------|------|-----|------|------|-----|------|
| Constant     | -    | -   | 2.7880** (2.5517) | -    | -   | 2.7084** (2.5433) |
| VAD_RATE (−1)| -    | 0.0373*** (5.3131) | -    | -   | 0.0391*** (4.9514) | -    | -   |
| EUIMP_mkt    | 1.9880 | 0.0303*** (2.6825) | 0.0097 (0.7669) | -    | -   | -    |
| EUEXP_mkt    | -    | -   | 1.8490 | 0.1313*** (4.4582) | 0.0260 (0.9529) |

Note: Robust t-statistics are presented in parentheses. *, **, *** indicate statistical significance at the 10%, 5% and 1% levels. Prob.>F is the probability of not including fixed effects. Multicollinearity was investigated by means of the variance inflation factor (VIF). For all econometric models, no multicollinearity problems were identified. In addition, the White test rejected the null hypothesis of heteroscedasticity. The aim of the Arellano-Bond tests is to check whether the idiosyncratic error term is serially correlated. The regression results show that there is no first-order autocorrelation and second-order autocorrelation based on Arellano-Bond AR(1) and AR(2) tests. Furthermore, the validity of the GMM estimator was confirmed by the Arellano–Bond test for AR(2): the test was statistically insignificant, it indicated a lack of the second-order serial correlation and it satisfied instrument validity. The Hansen J-statistic of over-identifying restrictions was not significant, therefore the null hypothesis of valid instruments could not be rejected. This confirmed the validity of the econometric models.
Model 2 investigated the evolution of value added rate under the influence of \textit{EUEXP}, \textit{EUIMPOL}, \textit{EUEXTRAOL}, \textit{EXTRAIMP} and \textit{EXTRAEXP} with panel GMM. That is, the variable \textit{EUEXP} and \textit{EXTRAEXP} had a positive impact, while \textit{EXTRAIMP} had a negative impact. If \textit{EUEXP} and \textit{EXTRAEXP} rose by one percent, \textit{VAD\_RATE} would follow a similar trend with 0.13 percentage points and 2.09 percentage points, respectively. At the same time, should \textit{EXTRAIMP} improve by one percent, \textit{VAD\_RATE} would decrease by 3.85 percentage points. The probabilities corresponding to the $J$-statistic test ($J = 24.58$, $p = 0.27$) and the Arellano-Bond test for AR(2) ($p = 0.81$) indicated that the combined effect of independent variables on value added rate was statistically significant.

When it estimated results via 2SLS panel (with cross-section random effects), the predictors explained 1.71\% of the variance in the outcome ($F = 1.96$, $p < 0.10$). That is, the impact of two predictors remained relevant. Namely, if \textit{EXTRAIMP} improved by one percentage point, \textit{VAD\_RATE} would decrease by 0.25 percentage points. At the same time, should \textit{EXTRAEXP} improve by one percent, \textit{VAD\_RATE} would increase by 0.15 percentage points.

Hence, the second research hypothesis was confirmed via the econometric models estimating the \textit{VAD\_RATE} outcome.

In terms of Model 3 that used panel GMM to investigate venture capital investments rate (Table 5), results showed that almost all independent variables played an important part. Namely, should \textit{EUIMP}, \textit{EUIMPOL} and \textit{EXTRAEXP} increase by one percent, the \textit{VENTURE} variable would slightly rise by 0.0008 percent, 0.0007 and 0.005 percentage points, respectively. At the same time, when \textit{EUEXTRAOL} augmented by one percent, \textit{VENTURE} would decrease by 0.003 percentage points. Overall, the probabilities corresponding to the $J$-statistic test ($J = 20.25$, $p = 0.57$) and the Arellano-Bond test for AR(2) ($p = 0.91$) indicated that the combined effect of the independent variables was statistically significant.

In the model that estimated \textit{VENTURE} via 2SLS panel (with cross-section random effects), the impact of the \textit{EUEXP}, \textit{EUIMPOL} and \textit{EXTRAEXP} variables remained significant ($F = 3.92$, $p < 0.05$). The model explained 4.32\% of the variance in the outcome. Namely, if \textit{EUEXP}, \textit{EUIMPOL} and \textit{EXTRAEXP} improved by one percentage point, VENTURE would decrease by 0.002 percentage points and, at the same time, it would rise by 0.002 percentage points.

Hence, the third research hypothesis was confirmed via the econometric models estimating venture capital investments rate.

According to Model 4 estimated via panel GMM, the variance in \textit{VENTURE} was explained by the majority of independent variables. That is, the variables \textit{EUEXP}, \textit{EUIMPOL} and \textit{EXTRAEXP} had a positive impact on the outcome evolution, while \textit{EUEXTRAOL} had a negative impact. If \textit{EUEXP}, \textit{EUIMPOL} and \textit{EXTRAEXP} rose by one percent, the outcome would follow a similar trend with 0.001 percentage points, 0.0007 percentage points and 0.006 percentage points, respectively. At the same time, should \textit{EUEXTRAOL} improve by one percent, \textit{VENTURE} would decrease by 0.003 percentage points. The probabilities corresponding to the $J$-statistic test ($J = 22.34$, $p = 0.44$) and the Arellano-Bond test for AR(2) ($p = 0.91$) indicated that the combined effect of the independent variables was statistically significant.

Once applying the 2SLS panel approach with random effects, the predictors explained 2.67\% of the variance in the outcome ($F = 3.95$, $p < 0.05$). That is, the impact of two predictors remained relevant. Namely, if \textit{EUEXTRAOL} improved by one percentage point, \textit{VENTURE} would decrease by 0.002 percentage points. At the same time, should \textit{EXTRAEXP} improve by one percent, \textit{VENTURE} would increase by 0.002 percentage points.

Hence, the fourth research hypothesis was confirmed via the econometric models estimating venture capital investments rate.

According to Model 5 estimated via panel GMM (Table 6), the variance in \textit{TURNOVER} was due to the majority of independent variables. Namely, should \textit{EUIMPOL}, \textit{EUEXTRAOL} and \textit{EXTRAEXP} increase by one percent, \textit{TURNOVER} would rise by 0.14 percentage points, 0.46 percentage points and 1.18 percentage points, respectively. At the same time, when
EXTRAIMP augmented by one percent, TURNOVER would decrease by 1.44 percentage points. Overall, the probabilities corresponding to the J-statistic test \((J = 22.66, p = 0.36)\) and the Arellano-Bond test for AR(2) \((p = 0.95)\) indicated that the combined effect of the independent variables on TURNOVER was statistically significant.

Note: Robust t-statistics are presented in parentheses. *, **, *** indicate statistical significance at the 10%, 5% and 1% levels. Prob > F is the probability of not including fixed effects. Multicollinearity was investigated by means of the variance inflation factor (VIF). For all econometric models, no multicollinearity problems were identified. In addition, the White test rejected the null hypothesis of heteroscedasticity. The aim of the Arellano-Bond tests is to check whether the idiosyncratic error term is serially correlated. The regression results show that there is no first-order autocorrelation and second-order autocorrelation based on Arellano-Bond AR(1) and AR(2) tests. Furthermore, the validity of the GMM estimator was confirmed by the Arellano-Bond test for AR(2): the test was statistically insignificant, it indicated a lack of the second-order serial correlation and it satisfied instrument validity. The Hansen J-statistic of over-identifying restrictions was not significant, therefore the null hypothesis of valid instruments could not be rejected. This confirmed the validity of the econometric models.
When using the 2SLS panel approach and cross-section random effects, only the impact of $\text{EU EXTRAOL}$ remained significant ($F = 14.23$, $p < 0.001$). The model explained 12.41% of the variance in the outcome. Namely, if $\text{EU EXTRAOL}$ improved by one percentage point, $\text{TURNOVER}$ would rise by 0.84 percentage points.

Hence, the fifth research hypothesis was confirmed via the econometric models estimating turnover from e-commerce rate.

Model 6 investigated the evolution of $\text{TURNOVER}$ depending on $\text{EU EXP}$, $\text{EU IMPOL}$, $\text{EU EXTRAOL}$, $\text{EXTRA IMP}$ and $\text{EXTRA EXP}$. In the case of the GMM approach, the variance in $\text{TURNOVER}$ was explained by all independent variables. That is, the variables $\text{EU IMPOL}$, $\text{EU EXTRAOL}$ and $\text{EXTRA EXP}$ had a positive impact, while $\text{EXTRA IMP}$ had a negative impact. If $\text{EU IMPOL}$, $\text{EU EXTRAOL}$ and $\text{EXTRA EXP}$ rose by one percent, $\text{TURNOVER}$ would register a similar trend with 0.14, 0.38 and 1.17 percentage points, respectively. At the same time, should $\text{EXTRA IMP}$ improve by one percent, $\text{TURNOVER}$ would decrease by 1.39%. The probabilities corresponding to the $J$-statistic test ($J = 23.57$, $p = 0.31$) and the Arellano-Bond test for AR(2) ($p = 0.81$) indicated that the combined effect of the independent variables was statistically significant.

After running the 2SLS panel approach with random effects, the model explained 11.17% of the variance in the outcome ($F = 13.03$, $p < 0.001$). That is, the impact of only one predictor remained relevant. Namely, if $\text{EU EXTRAOL}$ improved by one percentage point, $\text{TURNOVER}$ would decrease by 0.79 percentage points.

Hence, the sixth research hypothesis was confirmed via the econometric models estimating turnover rate.

5. Discussion and Conclusions

The present research study investigated the relationship between economic growth proxied by value added rate, venture capital investments rate and turnover from e-commerce rate and different variables concerning import and export business activities of small and medium enterprises (SMEs) in the EU-28 member states. The variables related to import and export were the following: intra-EU exports of goods; intra-EU imports of goods; intra-EU online importers; extra-EU online exporters; extra-EU exports of goods; extra-EU imports of goods. Variables of interest were retrieved from the Comext, Eurostat, Structural Business Statistics and World Bank databases. The period of analysis was 2005–2020.

Multiple methods were used in order to test six research hypotheses: descriptive statistics; correlation analysis; panel data modelling (panel generalized method of moments; two-stage least squares panel with cross-section weights) without time fixed effects. Econometric models supported all research hypotheses.

According to estimations, economic growth proxied by value added rate was mainly influenced by variables such as: intra-EU imports of goods, intra-EU exports of goods, extra-EU online exporters, extra-EU exports of goods and extra-EU imports of goods. Interestingly enough, online business activities of SMEs across the European Union represented an important engine that drove economic development. At the same time, economic relations developed between EU member states and countries outside the union proved to play an important part in driving economic growth.

With respect to venture capital investments rate, the highest impact was triggered by the variables extra-EU online exporters and extra-EU exports. From an economic standpoint, the rate of venture capital investments has increased mainly due to the intense trading activities of SMEs in the European Union. A second reason would be the increasing exports outside the EU that have generated additional financial resources. At the same time, extra-EU online exports have increased during the entire period of analysis and have positively influenced the countries’ economic growth levels.

In terms of turnover from e-commerce rate, results have shown that the strongest impact was yielded by the variables extra-EU imports and exports. As expected, the former had a negative effect, while the latter had a positive effect on economic growth.
As any other study, this research endeavor has certain limitations. First, the study considered export and import-related variables in order to examine economic growth. Upcoming research might take into account other macroeconomic variables that also influence economic growth. Second, the relationships were tested using data from SMEs operating across the European Union. Nevertheless, future studies could consider expanding the country sample beyond the borders of the union in order to test the research hypotheses.

All in all, the study emphasizes the importance of overall import and export activities of small and medium enterprises for the level of economic growth across EU member states. Starting from the fact that especially online activities have generated considerable increases for the EU-28 economies, the European Commission in general and national authorities in particular are called to support business endeavors that favor online trading and finance state budgets through their activities. At the end of the day, a substantial economic growth has a positive impact on the amount of tax money collected by public authorities [47], which can be efficiently used to provide high quality public goods. Hence, business endeavors of small and medium enterprises engender benefits not only for the economic market but also for the overall society.
