Abstract
This paper is concerned with the development and analysis of a mathematical model that is motivated by interstitial hydrodynamics and tissue deformation mechanics (poro-elasto-hydrodynamics) within an in-vitro solid tumour. The classical mixture theory is adopted for mass and momentum balance equations for a two-phase system. A main contribution of this study is we treat the physiological transport parameter (i.e., hydraulic resistivity) as anisotropic and heterogeneous, thus the governing system is strongly coupled and non-linear. We derived a weak formulation and then formulated the equivalent fixed-point problem. This enabled us to use the Galerkin method, and the classical results on monotone operators combined with the well-known Schauder and Banach fixed-point theorems to prove the existence and uniqueness of results.

1. Introduction
The study of fluid flow through porous media has gained the attention of many researchers over the years. Examples of natural porous materials are living tissues, rocks, soils, etc. On the other hand, there are manmade porous materials, e.g., concrete, foam, ceramic, etc. Because of their wide presence and hard-to-estimate effective properties, flow through porous material is studied by engineers and scientists. This leads to a coupled phenomenon where fluid flow and solid deformation in porous materials interplay. This is a classical problem in geomechanics and biomechanics. Recently, one of the most studied topics in the field of fluid mechanics is flow through biological tissues such as tumours, glycocalyx layers and articular cartilage. This paper deals with the mathematical modelling and analysis of the coupled phenomena of fluid flow and solid deformation (in short poro-elasto-hydrodynamics) within an in-vitro tumour model. Typically, a tumour is assumed to be a deformable porous medium that consists of multiple phases, e.g., one fluid phase and many solid ones. A tumour may exist in isolation (in-vitro) or may be present in normal tissue (in-vivo) [1]. Although the internal geometrical structure of tumours is complicated, developing mathematical models for approximate situations is very useful. Theoretical predictions generated from such approximate models may help to reduce the number of animal experiments that need to be carried out and also suggest new experimental programmes that identify optimal tumour therapy schedules [2].

Mathematical models of tumours in general can be divided into three categories: discrete, continuum and hybrid. Here, we focus on continuum models that treat cells as averaged populations and are based on the continuum mechanics approach to porous media combined with mixture theory [3]. The early
mathematical models on the avascular tumour growth [4] assumed that tumours are made of single type of cells having a constant density. However, various experimental, and theoretical evidence have shown that such a description is not sufficient to study the tumour dynamics [4, 5]. Hence, multiphase models came into play. In this case, one can consider density variations within mixture components to evaluate the evolution of partial stresses. Biot’s theory of poroelasticity and the theory of mixture are commonly adapted models to explore poro-elasto-hydrodynamics [1]. Alike continuum-level approaches involve the development of a set of equations to represent the mechanical behaviour of a soft tissue such as a tumour (which is assumed as a deformable porous material) at the macro scale, using a porous media approach.

The first multiphase model for tumours is proposed by Please et al. [6]. The authors proposed a diffusion equation for cell concentration and generalised Darcy equation for cells and water motion inside the tumour. Further, such multiphase models have been studied analytically and numerically by several authors, one can refer [5, 7, 8]. Sumets et al. [9] described a new boundary-integral representation for biphasic mixture theory, where they solved elastohydrodynamic-mobility problems using boundary element methods. Dey and Raja Sekhar [1] used a biphasic mixture model for poro-elasto-hydrodynamics and nutrient transport inside an in-vitro solid tumour. The authors assumed the presence of an unknown fluid source/sink in the model and biphasic mixture equations have been solved explicitly in the case of one-dimensional spherical geometry. Slvia and Wheeler [10] presented a coupled geomechanics and unsteady reservoir flow model using the theory of poroelasticity. They established the existence and uniqueness of a weak solution and computed a priori error estimates for the numerical solution with stress-dependent permeability. In [11], a non-linear model for a poroelastic medium (described by quasi-static Biot-equations) coupled to transport equations of substances was considered. They modelled time and space-dependent processes in deformable cellular tissues by the method of homogenisation, starting from a reactive flow system coupling mechanics at the pore scale. The model was analysed and the global-in-time existence and uniqueness of the solution were shown. Cao et al. [12] have considered a non-linear steady flow model in a deformable biological domain based on the theory of poroelasticity (non-linearity is due to the assumption of dilation-dependent interstitial permeability of the solid matrix). They established the existence and uniqueness of a weak solution. Looking through mentioned literature, we observe that there is a gap in dealing with the existence and uniqueness of corresponding biphasic mixture equations that describe the coupled phenomena of fluid flow and solid deformation within biomaterials such as tumours. Attempting to fill such a gap, Alam et al. [13, 14] developed a well-posedness theory and certain regularity results in 2d and 3d for poro-elasto-hydrodynamics model inside an in-vitro solid tumour. Further, in the case of an in-vivo solid tumour, Alam et al. [15] developed existence and uniqueness resulting in a weak sense for poro-elasto-hydrodynamics while assuming the hydraulic resistivity is heterogeneous and deformation dependent.

We note that, in general, poro-elasto-hydrodynamics models within a tumour may not lead directly to linear biphasic mixture equations. In practice, due to the non-uniform blood vessel distribution, the supply of fluids and macromolecules within a tumour is heterogeneous. As a consequence, physiological transport parameters (e.g., hydraulic resistivity or permeability) depend on space and deformation. For instance, in the case of soft permeable tissue and gel, Barry and Aldis [16] and Holmes and Mow [17] considered permeability depending exponentially on the strain. Also, some of the biological tissues and cells display anisotropic permeability [18]. In particular, articular cartilage typically exhibits anisotropic behaviour [19]. Further, in the case of multicellular tumour tissue, Giverso and Preziosi [20] followed Holmes and Mow [17] and considered that the permeability depends on the volumetric deformation (or strain). Dey and Sekhar [1] assumed that the hydraulic conductivity of soft tumour depends on the radial distance. These non-linear effects inserted in the physiological parameter yield non-linear biphasic mixture equations. As far as we know, for non-linear biphasic mixture models, there is a lack of literature regarding the existence, uniqueness and regularity of the solution. In this paper, we present a non-linear biphasic mixture model that represents poro-elasto-hydrodynamics, which do not account for any new growth of tumour cells. The physiological transport parameter (hydraulic resistivity) is assumed to be
deformation dependent, which yields the non-linearity in the model. We develop a local weak solvability theory.

1.1 Biphasic mixture theory

In this subsection, we introduce the generic governing equations. We use biphasic mixture theory to represent the fluid and solid phases of the tumour. Following [1, 8, 21], we apply the conservation of mass and momentum to the fluid and solid phases, viewing the fluid as viscous Newtonian and the solid as deformable, and accounting for momentum exchange between the two phases. Let $V_f$ and $V_s$ denote the velocities of the fluid and solid phases, respectively. The elastic moduli ($\nu$) represent the fluid and solid phases of the tumour. Following [1, 8, 21], we apply the conservation of mass and linear momentum balance equations for the fluid phase are given by

$$\frac{\partial (\rho \cdot V_f)}{\partial t} + \nabla \cdot (\rho V_f) = \rho \cdot \Sigma_f,$$

(1.1)

$$\rho_f \left( \frac{\partial V_f}{\partial t} + (V_f \cdot \nabla) V_f \right) = \nabla \cdot T_f + \Pi_f + b_f,$$

(1.2)

where $T_f$ denotes the stress tensor for the fluid phase

$$T_f = -[\phi_f P - \lambda_f \nabla \cdot V_f] + \mu_f \left[ \nabla V_f + \left( \nabla V_f \right)^T \right].$$

(1.3)

The corresponding mass and linear momentum equations for the solid phase are

$$\frac{\partial (\rho_s \cdot V_s)}{\partial t} + \nabla \cdot (\rho_s V_s) = \rho_s \cdot \Sigma_s,$$

(1.4)

$$\rho_s \left( \frac{\partial V_s}{\partial t} + (V_s \cdot \nabla) V_s \right) = \nabla \cdot T_s + \Pi_s + b_s,$$

(1.5)

where $T_s$ denotes the stress tensor for the solid phase

$$T_s = -[\phi_s P - \lambda_s \nabla \cdot V_s] + \mu_s \left[ \nabla V_s + \left( \nabla V_s \right)^T \right].$$

(1.6)

In Equations (1.1) and (1.4), $\Sigma_f$ and $\Sigma_s$ are fluid and solid source terms, respectively. $U_s$ denotes the displacement of the solid phase. Hence, $V_s = \frac{\partial U_s}{\partial t}$. The average interstitial fluid pressure is $P$ and $b_j$, $j = \{1, 2\}$ denotes the body force. Further, the volume fractions $\phi_f$ and $\phi_s$ are assumed to satisfy the following saturation assumption

$$\phi_f + \phi_s = 1.$$  

(1.7)

We suppose that the two phases interact together via the drag forces $\Pi_s$ and $\Pi_f$, which by Newton’s third law, are equal and opposite. Following [7, 8], we define

$$-\Pi_s = \Pi_f = K \left( V_s - V_f \right) - \left( \nabla \phi_s \right) P,$$

(1.8)

where $K = \frac{\mu_j}{k}$ is the hydraulic resistivity or drag coefficient, where $k$ is the permeability of the porous matrix (the precise nature of $K$ will be defined in the next section). Furthermore, $\mu_f$ ($\mu_s$) is the dynamic viscosity of the fluid phase (solid phase), while $\lambda_f$ and $\lambda_s$ denote the Lame coefficient and shear modulus of the fluid and solid phases. The elastic moduli $\chi_s$ and $\mu_s$ are related to the Young’s modulus ($Y$) and Poisson’s ratio ($\nu_p$) via the relationship

$$\chi_s = \frac{Y}{(1 + \nu_p)(1 - 2\nu_p)} \text{ and } \mu_s = \frac{Y}{2(1 + \nu_p)}.$$  

(1.9)
1.2 Main modelling assumptions

Having presented a more generic set of mixture theory equations in the absence of any assumptions or boundary conditions, here we list some biologically suitable assumptions restricted to a specific tumour model. Our choice of model is motivated by the study of an isolated (in-vitro) tumour that behaves as a heterogeneous deformable porous medium. Usually, tumour tissues are considered incompressible fluids with no voids present. It is assumed that each phase has an equal constant density. Suppose heterogeneous deformable porous medium. Usually, tumour tissues are considered incompressible fluid model. Our choice of model is motivated by the study of an isolated (in-vitro) tumour that behaves as a boundary conditions, here we list some biologically suitable assumptions restricted to a specific tumour sequence, the tumour grows in size. For a growing tumour, the permeability and the effective mechanics parameters ($\chi_s$ and $\mu_s$) may depend on the volume fraction of the cell population [8]. Moreover, the volume fractions depend on space. Hence, it is extremely difficult to analyse mathematically the growth model and fluid transport model simultaneously. To simplify this, we assume that the tumour tissue is not growing and all elastic parameters ($\chi_s$ and $\mu_s$, etc.) are independent of volume fractions. Further, we make the following modelling assumptions (A1)–(A4):

(A1) Nutrient perfusion and transport occur on much shorter timescales than the timescale for tumour cell growth. Accordingly, we view the tumour as a static, perfused biological domain. On the short timescale associated with nutrient transport to (and within) the tumour, cell death and proliferation are assumed to be negligible. Therefore, we fix $S_f = 0$ in the tumour and normal tissue regions. Further, on the timescale of interest, the solid volume fraction $\phi_s$ remains constant, and for simplicity, we assume it to be independent of spatial position and time as (see [1]).

(A2) A fluid source is attached to the mixture, hence $S_f \neq 0$, [1, 22].

(A3) Motion of the cells and interstitial fluid flow is so slow that the inertial terms can be neglected in both phases, see e.g. [8, 23].

(A4) Structure of the hydraulic resistivity: Various experimental and theoretical investigations indicate clearly that for the deformable porous medium (or soft biological tissue such as articular cartilage, arterial tissue and tumour), the permeability also called in this context hydraulic resistivity depends on stress, dilatation, volume fractions (porosity), etc. There are several analytical expressions for permeability that are used in literature such as $k(x) = \exp[mU'(x)]$, where $m$ is a constant and $U' = \frac{dU}{dx}$ with $U$ as displacement, while $k(x) = k_0/[1 - mU'(x)]$ or $k(x) = k_0/[1 + mU'(x)]$ for small $mU'(x)$, or $k(x) = k_0(\phi/\phi_0)^n$ [16, 17]. Here, $k_0$ is the permeability at reference porosity $\phi_0$ and $n$ is a variable that may be determined by fitting experimental data. In this framework, we propose two different cases. We assume that the hydraulic resistivity $K$ depends explicitly on (a) the solid phase displacement $U_s$ and (b) the strain/dilatation i.e. on $\nabla \cdot U_s$. In both of these cases, we admit anisotropic effects, i.e. $K$ is a square matrix of order $d = \{2, 3\}$. Note that in case (a), we do not use any specific, explicit expression of $K(U_s)$ in our analysis. One may think through the following choice

\[ K(U_s) = (\alpha_1 |U_s| + \alpha_3)I + (\alpha_1 - \alpha_2)\frac{U_sU_s'}{|U_s|}, \]

where $\alpha_i$ ($i = 1, 2, 3$) are real constants such that $\alpha_1 \geq 0, \alpha_2 \geq 0$ and $\alpha_3 > 0$. One can easily show that $K$ is Lipschitz and uniformly positive [24]. For case (b), one can think of a form $K(\nabla \cdot U_s) = (\gamma_1 + \gamma_2|\nabla \cdot U_s|)I$, where $\gamma_i \geq 0$ are real constants, and $I$ is the identity matrix. One can observe that $K$ is Lipschitz and uniformly positive. We will state further assumptions on $K$ in the next Section 3, [16, 17].

https://doi.org/10.1017/S0956792524000251 Published online by Cambridge University Press
The assumptions (A1)–(A4) are taken into account in Equations (1.1)–(1.8). This helps us to define a coupled non-linear system of steady-state mass and momentum balance equations in unknowns \((V_f, U_s, P)\) as follows:

\[
- \nabla \cdot \left( 2\mu_f D(V_f) + \lambda_f (\nabla \cdot V_f) I - \phi_f P I \right) + K(\zeta)V_f = b_f \quad \text{in} \quad \Omega,
\]

\[
- \nabla \cdot \left( 2\mu_s D(U_s) + \chi_s (\nabla \cdot U_s) I - \phi_s P I \right) - K(\zeta)V_f = b_s \quad \text{in} \quad \Omega,
\]

\[
\nabla \cdot (\phi_f V_f) = S_f \quad \text{in} \quad \Omega,
\]

where \(\zeta\) is either \(\nabla \cdot U_s\) or \(U_s\). Further, \(D(\cdot)\) denotes the deviatoric matrix, which is defined as \(D(u) = \frac{1}{2}(\nabla u + (\nabla u)^t)\), where \((\nabla u)^t\) denotes the transpose of the matrix \(\nabla u\). We have made the approximation \(V_s \approx \frac{\partial U_s}{\partial t} \approx 0\) which is consistent with the infinitesimal strain theory that is used in e.g. [1, 25]. The mass balance equations for the fluid phase include a source term \(S_f\), which models fluid exchange with vasculature and lymph vessels. For a closed mixture (for instance the case of avascular tumours), we consider \(S_f = 0\) so that \(\nabla \cdot (\phi_f V_f) = 0\). This is the counterpart of the incompressibility constraint. Note that in Equation (1.11), even though the density of each phase is constant, the vector \(V_f\) is not solenoidal.

On the other hand, when the external sources/sinks are attached to the mixture, we have \(S_f \neq 0\) [5, 22]. Typically, the fluid source \(S_f\) is assumed to be driven by the average transmural pressure and (trusting [1, 22]) takes the form

\[
S_f = -L_p \left( \frac{A}{V} \right) \{1 + L_r A_r\} (P - P_F),
\]

where \(L_p\) is the average hydraulic conductivity coefficient of capillary. In (1.12), \(A/V\) denotes the capillary surface area per unit tissue volume in the tumour tissue and \(L_r A_r\) denotes the ratio of the strength of distributed solute source through the vasculature and solute sink through the lymph vessels and \(P_F\) is the weighted vascular pressure.

### 1.3 Boundary conditions

The model that we have considered here is supposed to mimic an in-vitro tumour. Accordingly, we prescribe

\[
T_f \cdot n = T_\infty \quad \text{and} \quad U_s = 0 \quad \text{on} \quad \partial \Omega,
\]

where \(n\) is the outward normal unit vector to the boundary \(\partial \Omega\).

### 2. Non-dimensional equations

Using the transformations \(\hat{x} = \frac{x}{R}, \hat{V} = R V, \hat{P} = \frac{P}{P_F}, \hat{V}_f = \frac{V_f}{R \mu_f}, \hat{U}_s = \frac{U_s}{R \mu_f}, K = \hat{K} K_d\), where \(K_d\) is the hydraulic resistivity (drag coefficient) of the tumour tissue in the absence of deformation, \(R\) is the length
of the edge of the \( d \)-cube in which \( \Omega \) is contained. The following dimensionless form of the governing Equations (1.9)–(1.11) (‘hat’ is dropped for convenience) is available in \( \Omega \)

\[
-\nabla \cdot \left( 2D(V) + \frac{\lambda_f}{\mu_f} (\nabla \cdot V) I - \phi_f P I \right) + \frac{1}{Da} K(\zeta)V = b_f, \tag{2.1}
\]

\[
-\nabla \cdot \left( \frac{\rho_f}{1 + v_p} \frac{D(U)}{(1 + v_p)(1 - 2v_p)} (\nabla \cdot U) I - \phi_f P I \right) - \frac{1}{Da} K(\zeta)V = b_f, \tag{2.2}
\]

\[
\nabla \cdot (\phi_f V) = -\alpha_f^2 (1 + LA_s)(P - 1). \tag{2.3}
\]

In (2.1) and (2.2), \( b_f \) and \( b_i \) are modified non-dimensional body forces, and \( \rho_f = \gamma R^2 \rho_f / \mu_f^2 \) is the dimensionless Young’s modulus \( \zeta \) associated with the solid phase. It contains the response of the solid phase (cellular phase + extracellular matrix) towards viscous drag due to interstitial fluid movement. \( \alpha_f^2 = L_p(A/V)\mu_f^2 \) is the strength of solute source, and \( Da = \frac{K_{eff}}{D} \) is the Darcy number (permeability parameter). The corresponding boundary conditions are

\[
\left( 2D(V) + \frac{\lambda_f}{\mu_f} (\nabla \cdot V) I - \phi_f P I \right) \cdot n = T_\infty \text{ and } U_s = 0 \text{ on } \partial \Omega. \tag{2.4}
\]

For the sake of writing convenience, set \( \lambda = \frac{\gamma}{R^2}, \) \( \alpha_1 = \frac{\gamma}{R^2} (1 + v_p), \) \( \alpha_2 = \frac{\gamma}{R^2} (1 + v_p)(1 - 2v_p), \) and \( a_0 = \alpha_f^2 (1 + L_s A_s). \)

Observe that the system of Equations (2.1)–(2.3) is non-linear and fully coupled whenever \( \zeta \) is equal to either \( U_s \) or \( \nabla \cdot U_s, \) which is our primary interest for now. The main aim is to study the well-posedness of the non-linear system (2.1)–(2.3) subject to the data (2.4).

3. Well-posedness of the auxiliary sub-problems

\( V_f, P, U, \) are the unknown functions in the system of Equations (2.1)–(2.3). We assume the following:

(A) The parameters \( \phi_f > 0, \phi_i > 0, \lambda \geq 0, \alpha_1 > 0, \alpha_2 > 0, a_0 > 0, Da > 0 \) are known real constants, and the functions \( b_f \in L^2(\Omega)^d \) where \( j = f, s, \) \( T_\infty \in L^2(\partial \Omega)^d \) are also known. \( c_0 > 0, c_p > 0, c_r > 0, c_s > 0 \) are some real constants that appear in Korn’s, Poincare’s, trace and Sobolev’s inequalities, respectively.\(^1\)

(B) Let \( K : \mathbb{R}^d \to \mathbb{R}^{d^2} \) be a symmetric, uniformly bounded and positive definite matrix. This ensures that there exist positive constants \( k_1 \) and \( k_2 \) such that for all \( \xi, \theta \in \mathbb{R}^d, \) we have:

\[
(i) \ k_1 |\xi| \leq K(\xi)\xi \quad \text{and} \quad (ii) \ ||K(\xi)|| \leq k_2, \tag{3.1}
\]

\( || \cdot || \) denotes the Euclidean norm.

(C) We assume that the hydraulic resistivity \( K \) is Lipschitz continuous. To this extent, let us assume that there exists a constant \( k_L > 0 \) such that

\[
||K(x) - K(y)|| \leq k_L ||x - y|| \quad \text{for all } x, y \in \mathbb{R}^d. \tag{3.2}
\]

3.1 Concept of weak formulation

Choose the triplet of test functions \( (W, Z, q) \in H^1(\Omega)^d \times H_0^1(\Omega)^d \times L^2(\Omega) \). Taking the scalar product of (2.1) with \( W, (2.2) \) with \( Z \) and (2.3) with \( q, \) and using the boundary conditions (2.4), we get the following non-linear weak formulation:

\(^1\)We refer to the Appendix section for details on function spaces and other preliminary results.
Find the triplet \((V_f, U_r, P) \in H^1(\Omega)^d \times H_0^1(\Omega)^d \times L^2(\Omega)\) such that
\[
2(D(V_f) : D(W))_\Omega + \lambda(\nabla \cdot V_f, \nabla \cdot W)_\Omega - \phi_f(P, \nabla \cdot W)_\Omega + \frac{1}{Da}(K(\xi)V_f, W)_\Omega = (b_f, W)_\Omega + (T_\infty, W)_\Omega\tag{3.3}
\]
holds for all \((W, Z, q) \in H^1(\Omega)^d \times H_0^1(\Omega)^d \times L^2(\Omega)\). Here in \(\xi\) is \(U_r\) and \(\nabla \cdot U_r\).

**Lemma 1.** (Equivalence of weak formulations) Suppose that parameters and data satisfy assumptions (A) and (B). Then any solution (in the sense of distributions) \((V_f, U_r, P) \in H^1(\Omega)^d \times H_0^1(\Omega)^d \times L^2(\Omega)\) of the coupled problem (2.1)–(2.4) is also a solution to the variational problem (3.3)–(3.5). Conversely, any solution to the weak problem (3.3)–(3.5) satisfies (2.1)–(2.4) in the sense of distributions.

The proof follows using standard arguments. We omit to show it.

### 3.2 Decoupled problem corresponding to (3.3)–(3.5), Case (a): \(K(\xi) = K(U_r)\)

We note that the weak formulation (3.3)–(3.5) can be decoupled concerning the unknowns \((V_f, P)\) and \(U_r\). In case (a), we are dealing with \(K(\xi) = K(U_r)\), which is a non-linear function of \(U_r\) and satisfies assumptions (3.1) and (3.2). In this case, we can solve (3.3)–(3.5) sequentially, that is, given \(\xi \in H_0^1(\Omega)^d\) find \((V_f, P) \in H^1(\Omega)^d \times L^2(\Omega)\) such that
\[
(Q_{w1}(\xi)) \begin{cases} 
2(D(V_f) : D(W))_\Omega + \lambda(\nabla \cdot V_f, \nabla \cdot W)_\Omega - \phi_f(P, \nabla \cdot W)_\Omega \\
+ \frac{1}{Da}(K(\xi)V_f, W)_\Omega + \phi_f(\nabla \cdot V_f, q)_\Omega = (b_f, W)_\Omega + (T_\infty, W)_\Omega + (a_0, q)_\Omega 
\end{cases}
\]
holds for all \((W, q) \in H^1(\Omega)^d \times L^2(\Omega)\), and then for a given pair \((V_f, P) \in H^1(\Omega)^d \times L^2(\Omega)\), find \(U_r \in H_0^1(\Omega)^d\) such that
\[
(Q_{w2}(U_r)) \begin{cases} 
2\alpha_1(D(U_r) : D(Z))_\Omega + \alpha_2(\nabla \cdot U_r, \nabla \cdot Z)_\Omega = \phi_f(P, \nabla \cdot Z)_\Omega \\
+ \frac{1}{Da}(K(U_r)V_f, Z)_\Omega = (b_f, Z)_\Omega 
\end{cases}
\]
holds for all \(Z \in H_0^1(\Omega)^d\). For notational convenience, we denote combined problem as \((Q_{w1}(\xi)) - (Q_{w2}(U_r))\).

### 3.3 Decoupled problem corresponding to (3.3)–(3.5), Case (b): \(K(\nabla \cdot \xi) = K(\nabla \cdot U_r)\)

We can solve (3.3)–(3.5) sequentially, that is, for a given \(\xi \in H_0^1(\Omega)^d\) find \((V_f, P) \in H^1(\Omega)^d \times L^2(\Omega)\) such that
\[
(Q_{w1}(\nabla \cdot \xi)) \begin{cases} 
2(D(V_f) : D(W))_\Omega + \lambda(\nabla \cdot V_f, \nabla \cdot W)_\Omega - \phi_f(P, \nabla \cdot W)_\Omega \\
+ \frac{1}{Da}(K(\nabla \cdot \xi)V_f, W)_\Omega + \phi_f(\nabla \cdot V_f, q)_\Omega = (b_f, W)_\Omega + (T_\infty, W)_\Omega + (a_0, q)_\Omega 
\end{cases}
\]
holds for all \((W, q) \in H^1(\Omega)^d \times L^2(\Omega)\), and then for a given pair \((V_f, P) \in H^1(\Omega)^d \times L^2(\Omega)\), find \(U_r \in H_0^1(\Omega)^d\) such that
\[
(Q_{w2}(\nabla \cdot U_r)) \begin{cases} 
2\alpha_1(D(U_r) : D(Z))_\Omega + \alpha_2(\nabla \cdot U_r, \nabla \cdot Z)_\Omega = \phi_f(P, \nabla \cdot Z)_\Omega \\
+ \frac{1}{Da}(K(\nabla \cdot U_r)V_f, Z)_\Omega = (b_f, Z)_\Omega 
\end{cases}
\]
holds for all \( Z \in H^1_0(\Omega)^d \). For notational convenience, we denote combined problem as \((Q_{w_1}(\nabla \cdot \varsigma)) - (Q_{w_2}(\nabla \cdot U_i))\).

### 3.4 Case (a): existence and uniqueness results for \((Q_{w_1}(\varsigma))\)

In order to solve weak formulation \((Q_{w_1}(\varsigma))\), we use the following method. We rephrase the weak formulation \((Q_{w_1}(\varsigma))\) into an abstract setting. Set \( \mathbb{V} = H^1(\Omega)^d \times L^2(\Omega) \). To do so, define a mapping \( \mathcal{H}_\varsigma \) from \( \mathbb{V} \) to \( \mathbb{V} \) by

\[
\langle \mathcal{H}_\varsigma(V_f, P), (W, q) \rangle = 2(D(V_f)) : (D(W))_\Omega + \lambda(\nabla \cdot V_f, \nabla \cdot W)_\Omega - \phi_f(P, \nabla \cdot W)_\Omega + \frac{1}{Da}(K(\varsigma)V_f, W)_\Omega + \phi_r(\nabla \cdot V_f, q)_\Omega + a_0(P, q)_\Omega - [(b_f, W)_\Omega + (T_\infty, W)_\Omega + (a_0, q)_\Omega].
\]

Using the mapping \( \mathcal{H}_\varsigma \), the variational formulation \((Q_{w_1}(\varsigma))\) can equivalently be written as: for a given \( \varsigma \in H^1_0(\Omega)^d \), find \( (V_f, P) \in \mathbb{V} \) such that

\[
\langle \mathcal{H}_\varsigma(V_f, P), (W, q) \rangle = 0 \quad \text{for all} \quad (W, q) \in \mathbb{V}.
\]

Conversely, if (3.7) holds, then (2.1) and (2.3) with the first boundary condition in the equation (2.4) satisfy in the sense of distributions. Hence, our immediate task is to find a pair \((V_f, P) \in \mathbb{V}\) that satisfies (3.7). In order to do so, we proceed as follows. The mapping \( \mathcal{H}_\varsigma \) satisfies the following lemma:

**Lemma 3.1.** Suppose that parameters and data satisfy assumptions (A) and (B). If \( \mathcal{H}_\varsigma \) is a mapping from \( \mathbb{V} \) into itself defined by (3.6), then the following statements hold:

(i) \( \mathcal{H}_\varsigma \) is continuous.

(ii) There exists a real number \( r > 0 \) such that

\[
\langle \mathcal{H}_\varsigma(V), V \rangle > 0, \quad \text{for all} \quad V \in \mathbb{V} \quad \text{with} \quad ||V||_\mathbb{V} = r,
\]

i.e., \( \mathcal{H}_\varsigma \) is coercive on a ball of radius \( r \) in \( \mathbb{V} \). Here, for any \( V = (V_f, P) \in \mathbb{V} = H^1(\Omega)^d \times L^2(\Omega) \), \( ||\cdot||_\mathbb{V} \) is defined as

\[
||V||^2_\mathbb{V} = ||V_f||^2_\Omega + ||P||^2_{0, \Omega}.
\]

**Proof.** (i) The continuity of the mapping \( \mathcal{H}_\varsigma \) can be shown using the continuity of scalar product. Indeed, let \( (V^m)_{m \geq 1} = [(V^m_f, P^m)]_{m \geq 1} \) be any sequence in \( \mathbb{V} \) that converges strongly to \( V = (V_f, P) \in \mathbb{V} \) as \( m \to \infty \), i.e.

\[
||V^m_f - V_f||_{1, \Omega} \to 0, \quad ||P^m - P||_{0, \Omega} \to 0 \quad \text{as} \quad m \to \infty.
\]

Relying on the definition of \( \mathcal{H}_\varsigma \) and on Cauchy-Schwarz inequality, we get

\[
||\langle \mathcal{H}_\varsigma(V^m), (W, q) \rangle - \langle \mathcal{H}_\varsigma(V), (W, q) \rangle|| \leq 2||D(\theta_f(V^m) - V_f)||_{0, \Omega}||D(W)||_{0, \Omega} + \lambda||\nabla \cdot (V^m_f - V_f)||_{0, \Omega}||\nabla \cdot W||_{0, \Omega} + \phi_r||P^m - P||_{0, \Omega}||\nabla \cdot W||_{0, \Omega} + \frac{k_2}{Da}||V^m_f - V_f||_{0, \Omega}||W||_{0, \Omega} + \phi_r||\nabla \cdot (V^m_f - V_f)||_{0, \Omega}||q||_{0, \Omega} + a_0||P^m - P||_{0, \Omega}||q||_{0, \Omega}.
\]

Using (3.8), we obtain

\[
||\langle \mathcal{H}_\varsigma(V^m, P^m) - \mathcal{H}_\varsigma(V_f, P), (W, q) \rangle|| \to 0 \quad (W, q) \text{ as } m \to \infty.
\]

This argument establishes the continuity of \( \mathcal{H}_\varsigma \).

(ii) For any \( V = (V_f, P) \in \mathbb{V} \), we have

\[
\langle \mathcal{H}_\varsigma(V), V \rangle = 2||D(V_f)||^2_{0, \Omega} + \lambda||\nabla \cdot V_f||^2_{0, \Omega} - \phi_f(P, \nabla \cdot V_f)_\Omega + \frac{1}{Da}(K(\varsigma)V_f, V_f)_\Omega + \phi_r(\nabla \cdot V_f, q)_\Omega + a_0||P||^2_{0, \Omega} - [(b_f, V_f)_\Omega + (T_\infty, V_f)_\Omega + (a_0, P)_\Omega].
\]

https://doi.org/10.1017/S0956792524000251 Published online by Cambridge University Press
Using Cauchy-Schwarz, Korn’s and trace inequalities, we obtain
\[
\langle \mathcal{H}_\xi(V), V \rangle \geq \alpha_2 ||V||_{L^2}^2 + \lambda ||\nabla \cdot V||_{L^2}^2 + a_0 ||P||_{L^2}^2
\]
\[- (||b_f||_{L^2} + \sqrt{c_f} ||T_\Omega||_{L^2}) ||V||_{L^2} - ||a_0||_{L^2} ||P||_{L^2}.
\]
(3.10)
where \( \alpha = \frac{1}{c_2} \min\{2, \frac{k}{b_0}\} \). Further, (3.10) can be rewritten as
\[
\langle \mathcal{H}_\xi(V), V \rangle \geq \alpha_3(\|V\|^2_{L^2} + \|P\|^2_{L^2}) - \alpha_4\|V\|_{L^2},
\]
where
\[
\alpha_3 = \min\{\alpha, a_0\},
\]
\[
\alpha_4 = [(||b_f||_{L^2} + \sqrt{c_f} ||T_\Omega||_{L^2})^2 + ||a_0||_{L^2}^2]^{1/2}.
\]
(3.13)
If \( ||V||_{L^2} = r_0 \) for some \( r_0 > 0 \), then we have
\[
\langle \mathcal{H}_\xi(V), V \rangle > 0 \quad \forall V \in \mathcal{Y}, \text{ when } r_0 > \frac{\alpha_4}{\alpha_3}.
\]
(3.14)
This completes the proof of Lemma 3.1.

**Remark 3.2.** Note that \( \lambda = \frac{\mu}{\nu} \) (which is the ratio of the two viscosity coefficients) plays a significant role in the coercivity proof. The literature [26, 27] suggests that researchers have debated on the sign (or value) of \( \lambda \). According to the well-known Stokes-hypothesis, \( \lambda = -2/3 \) [27]. On the other hand, the existing literature also suggests that this ratio can be non-negative [26]. Thus, we consider both of these possibilities. If \( \lambda \geq 0 \), then the coercivity of \( \mathcal{H}_\xi \), as shown by us in (3.14), holds. However, when \( \lambda < 0 \) (i.e. a typical Stokes hypothesis), the coercivity of \( \mathcal{H}_\xi \) holds with relevant restrictions on the constants. For instance, when \( \lambda < 0 \), the mapping \( \mathcal{H}_\xi \) is coercive if \( \alpha = \frac{1}{c_2} \min\{2, \frac{k}{b_0}\} > 2/3 \). For convenience from here onward, we assume \( \lambda \) to be a non-negative constant.

Based on Lemma A.1 (see Appendix A), we now present the following existence results.

**Theorem 3.3.** Suppose that (A) and (B) hold. Then for a given \( \xi \in H^1_0(\Omega)^d \), the problem (3.7) has at least one solution \( (V_f, P) \in \mathcal{Y} = H^1(\Omega)^d \times L^2(\Omega) \) satisfying the problems (2.1) and (2.3) with the first boundary condition in the equation (2.4) in the sense of distributions. Moreover, the solution \( (V_f, P) \) satisfies the following a priori bound
\[
||V||_{L^2}^2 + ||P||_{L^2}^2 \leq \left( \frac{\alpha_4}{\alpha_3} \right)^2.
\]
(3.15)
**Proof.** To prove this result, we use the Galerkin method. The spaces \( H^1(\Omega)^d \times L^2(\Omega) \) are separable Hilbert spaces. Hence, there exist corresponding bases \( \{W_i\}_{i=1}^\infty \) and \( \{q_i\}_{i=1}^\infty \) of smooth functions. Let \( \mathcal{Y}_m \) be the space spanned by \( \{(W_i, q_i)\}_{i=1}^m \). The scalar product on \( \mathcal{Y}_m \) is induced by the scalar product of \( \mathcal{Y} \). We define the approximate solution \( (V^m_f, P^m) \) as follows:
\[
V^m_f = \sum_{i=1}^m a_i W_i, \quad P^m = \sum_{i=1}^m c_i q_i,
\]
(3.16)
with
\[
(Q_m(\xi)) = 2(\xi(D(V^m_f), D(W)_\Omega) + \lambda(\nabla \cdot V^m_f, \nabla \cdot W)_\Omega - \phi_f(P^m, \nabla \cdot W)_\Omega) + \frac{1}{b_f} (K(\xi) V^m_f, W)_\Omega + \phi_f(\nabla \cdot V^m_f, q)_\Omega + a_0(P^m, q)_\Omega
\]
\[= (b_f, W)_\Omega + (T_\Omega, W)_\Omega + (a_0, q)_\Omega,
\]
holding for all \( (W, q) \in \mathcal{Y}_m \) with \( a_i, b_i, c_i \in \mathbb{R} \), for \( i = 1, 2, \ldots, m \). The task now is to ensure the existence of solutions to \( (Q_m(\xi)) \) and show that \( (Q_m(\xi)) \) recovers \( (Q_{\mathcal{Y}_m}(\xi)) \) as \( m \to \infty \). The linear structure of \( (Q_m(\xi)) \) suggests that weak convergence is enough to pass the limit. Hence, in order to do so, we define a mapping \( \mathcal{H}_m \) inspired by the structure of mapping \( \mathcal{H} \) as
\[
\langle \mathcal{H}_m(V_f, P), (W, q) \rangle = \langle \mathcal{H}_m(V_f, P), (W, q) \rangle, \quad \text{for all } (W, q) \in \mathcal{Y}_m
\]
(3.17)
where $\mathcal{H}_\xi$ is defined in (3.6). From Lemma 3.1, we deduce that the mapping $\mathcal{H}_m^\xi$ satisfies the conditions needed for Lemma A.1 (see Appendix A) and hence, there exists a solution $(\mathbf{V}_m^f, P^m) \in \mathbb{Y}_m$ for each $m$ such that

$$
\langle \mathcal{H}_\xi^m(\mathbf{V}_m^f, P^m), (\mathbf{W}, q) \rangle = 0, \text{ for all } (\mathbf{W}, q) \in \mathbb{Y}_m.
$$

(3.18)

It follows that $(\mathbf{V}_m^f, P^m)$ satisfy $(Q_m(\xi))$ and $\alpha, \gamma$ can be determined.

**Energy Estimates:** Let $\mathbf{W} = \mathbf{V}_m^f$, and $q = P^m$ in $(Q_m(\xi))$, then by performing calculations similar to those leading to (3.11), we obtain

$$
\alpha_3(||\mathbf{V}_m^f||_{1, \Omega}^2 + ||P^m||_{0, \Omega}^2) - \alpha_4||V_m^f, P^m||_{1, 0, \Omega} \leq 0,
$$

(3.19)

where $\alpha_3$ and $\alpha_4$ are defined in (3.12)–(3.13). Consequently,

$$
||\mathbf{V}_m^f||_{1, \Omega}^2 + ||P^m||_{0, \Omega}^2 \leq \left(\frac{\alpha_4}{\alpha_3}\right)^2.
$$

(3.20)

Inequality (3.20) implies that the sequence $\{(V_m^f, P_m^m)\}_{m \geq 1}$ is uniformly bounded in $\mathbb{Y}$. Hence, it has a sub-sequence $\{(V_m^f, P_m^m)\}_{m \geq 1}$ (for convenience, we denote it by the same symbol) and a pair $(\mathbf{V}_f, P) \in \mathbb{Y}$ such that

$$
(V_m^f, P_m^m) \to (\mathbf{V}_f, P) \text{ as } m \to \infty \text{ weakly in } \mathbb{Y}.
$$

(3.21)

By taking the limit in (3.18) and using the weak convergence (3.21), we get

$$
\langle \mathcal{H}_\xi(\mathbf{V}_f, P), (\mathbf{W}, q) \rangle = 0, \text{ for all } (\mathbf{W}, q) \in \mathbb{Y}_m.
$$

(3.22)

A continuity argument shows that (3.22) holds for any $(\mathbf{W}, q) \in \mathbb{Y}$. Hence, $(\mathbf{V}_f, P)$ is a solution of (3.7) and equivalently, of the weak formulation $(Q_{w_1}(\xi))$. Using the lower semi-continuity property of norm in (3.20), we can achieve the following a priori bound on solution $(\mathbf{V}_f, P)$ given by

$$
||\mathbf{V}_f||_{1, \Omega}^2 + ||P||_{0, \Omega}^2 \leq \left(\frac{\alpha_4}{\alpha_3}\right)^2.
$$

(3.23)

**Proposition 3.4.** Suppose the hypotheses of Theorem 3.3 hold. Then, the weak formulation $(Q_{w_1}(\xi))$ has a unique solution that depends continuously on the given data.

**Proof.** **Uniqueness:** Let $(\mathbf{V}_1^i, P^i)$ and $(\mathbf{V}_2^i, P^2)$ be two solutions that satisfy Equation (3.7) or equivalently the weak formulation $(Q_{w_1}(\xi))$. Define $(\mathbf{V}_f, P) = (\mathbf{V}_1^i - \mathbf{V}_2^i, P^1 - P^2)$. Then, from (3.7), we have

$$
\langle \mathcal{H}_\xi(\mathbf{V}_1^i, P^i) - \mathcal{H}_\xi(\mathbf{V}_2^i, P^2), (\mathbf{W}, q) \rangle = 0
$$

(3.24)

for all $(\mathbf{W}, q) \in \mathbb{Y}$. Replace $(\mathbf{W}, q)$ by $(\mathbf{W}, P)$ in (3.24) and using the definition of $\mathcal{H}$, we find

$$
\alpha||V_f||_{1, \Omega}^2 + \lambda||\nabla \cdot V_f||_{0, \Omega}^2 + a_0||P||_{0, \Omega}^2 \leq 0.
$$

The above implies $V_f = 0$, $u_i = 0$ and $P = 0$ almost everywhere in $\Omega$. Hence, the weak formulation $(Q_{w_1}(\xi))$ has a unique solution.

**Continuous dependence:** Let $(\mathbf{V}_1^i, P^i)$ and $(\mathbf{V}_2^i, P^2)$ be two solutions of $(Q_{w_1}(\xi))$ corresponding to the two sets of data $(\mathbf{T}_{\infty_1}, b_{j,1}, a_{0,1})$ and $(\mathbf{T}_{\infty_2}, b_{j,2}, a_{0,2})$, then the difference $(\mathbf{V}_f, P) = (\mathbf{V}_1^i - \mathbf{V}_2^i, P^1 - P^2)$ satisfies

$$
\alpha||V_f||_{1, \Omega}^2 + \lambda||\nabla \cdot V_f||_{0, \Omega}^2 + a_0||P||_{0, \Omega}^2

- (||b_f||_{0, \Omega} + \sqrt{c_i}|||T_{\infty_1}||_{0, \Omega})||V_f||_{1, \Omega} - ||a_0||_{0, \Omega})||P||_{0, \Omega} \leq 0,
$$

where $c_i$ is a constant. Hence, the weak formulation $(Q_{w_1}(\xi))$ has a unique solution.
or,
\[
||V_j^1 - V_j^2||_{1,\Omega}^2 + ||P^1 - P^2||_{0,\Omega}^2 \leq \frac{1}{\alpha^2} \left[ (||b_j,1 - b_j,2||_{0,\Omega} + \sqrt{c_1}||T_{\infty,1} - T_{\infty,2}||_{0,\Omega})^2 + ||a_{0,1} - a_{0,2}||_{0,\Omega}^2 \right].
\] (3.25)

Thus, if \((T_{\infty,1}, b_j,1, a_{0,1})\) is close to \((T_{\infty,2}, b_j,2, a_{0,2})\), then the left-hand side of (3.25) (the difference of solutions) must be small. This establishes the well-posedness of the auxiliary linear problem \((Q_{w_1}(\varsigma))\).

Next, we would like to consider the sub-problem, \((Q_{w_2}(\nabla \cdot U_i))\).

### 3.5 Case (a): existence and uniqueness results for \((Q_{w_2}(U_i))\)

We note that \(K(\varsigma) = K(U_i)\) is a non-linear function of \(U_i\) (see assumption (A4) in Subsection 1.2) which makes \((Q_{w_2}(U_i))\) a semilinear problem. By introducing a semilinear form \(B(\cdot, \cdot) : H_0^1(\Omega)^d \times H_0^1(\Omega)^d \rightarrow \mathbb{R}\) that is given by
\[
B(U_i, Z) = 2\alpha_1(D(U_i) : D(Z))_\Omega + \alpha_2(\nabla \cdot U_i, \nabla \cdot Z)_\Omega - \frac{1}{Da}(K(U_i)V_f, Z)_\Omega
\] (3.26)
and a linear form \(L : H_0^1(\Omega)^d \rightarrow \mathbb{R}\) defined as
\[
L(Z) = \phi_f(P, \nabla \cdot Z)_\Omega + (b, Z)_\Omega,
\] (3.27)
weak problem \((Q_{w_2}(U_i))\) can be rewritten as an abstract formulation. For a given pair \((V_f, P) \in H^1(\Omega)^d \times L^2(\Omega)\), find \(U_i \in H_0^1(\Omega)^d\) such that
\[
B(U_i, Z) = L(Z) \text{ for all } Z \in H_0^1(\Omega)^d.
\] (3.28)

In order to show existence and uniqueness results for problem (3.28), we will use the Browder-Minty theorem (see Thereom A.3, Appendix A), which is based on the monotone operator approach. To justify the hypotheses of the Browder-Minty theorem, we prove the following results in the form of lemmas.

**Lemma 2.** The correspondence \(Z \mapsto B(U_i, Z)\) is a bounded linear operator and \(L \in (H_0^1(\Omega)^d)^*\).

**Proof.** Clearly, the mapping \(Z \mapsto B(U_i, Z)\) is linear (obvious) and bounded. Indeed, using Cauchy-Schwarz, Hölder’s and Sobolev inequalities, we find
\[
|B(U_i, Z)| \leq 2\alpha_1||D(U_i)||_{0,\Omega}||D(Z)||_{0,\Omega} + \alpha_2||\nabla \cdot U_i||_{0,\Omega}||\nabla \cdot Z||_{0,\Omega}
+ \frac{1}{Da}||K(U_i)||_{L^\infty(\Omega)}||V_f||_{0,\Omega}||Z||_{0,\Omega} \leq \left(2\alpha_1 + \alpha_2\right)||\nabla U_i||_{0,\Omega}
+ \frac{k_2\sqrt{c_p}}{Da}||V_f||_{0,\Omega}||\nabla Z||_{0,\Omega}.
\] (3.29)

Now, \(L\) is linear (obvious) and bounded. Indeed, we have
\[
|L(Z)| \leq (\phi_f||P||_{0,\Omega} + \sqrt{c_p}||b||_{0,\Omega})||\nabla Z||_{0,\Omega}.
\] (3.30)
This implies \(L \in (H_0^1(\Omega)^d)^*\).

The Lemma 2 implies that there exists an operator (non-linear) \(A : H_0^1(\Omega)^d \rightarrow (H_0^1(\Omega)^d)^* = H^{-1}(\Omega)^d\) with
\[
(AU_i, Z) = B(U_i, Z).
\] (3.31)
Thus, the variational problem (3.28) equivalently reduces to the operator equation: find \(U_i \in H_0^1(\Omega)^d\) such that
\[
AU_i = L
\] (3.32)
in the sense
\[
(AU_i, Z) = L(Z), \text{ for all } Z \in H_0^1(\Omega)^d.
\] (3.33)
Further, estimate (3.29) implies the non-linear operator $A$ is bounded. Indeed,

\[ ||A\mathbf{u}_i||_{H^{-1}(\Omega)} \leq \left[ (2\alpha_1 + \alpha_2)||\nabla \mathbf{u}_i||_{\Omega} + \frac{k_2\sqrt{c_\theta}}{Da}||\mathbf{v}_j||_{\Omega} \right]. \tag{3.34} \]

**Lemma 3.** If \( \frac{2\alpha_1}{c_k} > \frac{k_2c_4\sqrt{c_\theta}}{\alpha_5Da} \), then the semilinear form $B(\cdot, \cdot)$ is elliptic that is there exists a constant $c > 0$ such that

\[ B(U^1_j, U^1_j - U^2_j) - B(U^2_j, U^1_j - U^2_j) \geq c||\nabla U^1_j - \nabla U^2_j||_{\Omega}. \tag{3.35} \]

Note: This lemma implies that $A$ is strongly monotone.

**Proof:** Indeed, consider

\[ (A\mathbf{u}_i^1 - A\mathbf{u}_i^2, U^1_j - U^2_j) = B(U^1_j, U^1_j - U^2_j) - B(U^2_j, U^1_j - U^2_j) \]

\[ - \frac{1}{Da}((K(U^1_j) - K(U^2_j))\mathbf{v}_j, U^1_j - U^2_j) \geq 2\alpha_1||D(U^1_j) - D(U^2_j)||_{\Omega} \]

\[ + \alpha_2||\nabla \cdot U^1_j - \nabla \cdot U^2_j||_{\Omega}^2 - \frac{1}{Da}||K(U^1_j) - K(U^2_j)||_{L^2(\Omega)}||\mathbf{v}_j||_{L^2(\Omega)}||U^1_j - U^2_j||_{L^2(\Omega)} \]

\[ \geq \frac{2\alpha_1}{c_k}||\nabla U^1_j - \nabla U^2_j||_{\Omega}^2 - \frac{k_4c_4\sqrt{c_\theta}}{\alpha_5Da}||\nabla U^1_j - \nabla U^2_j||_{\Omega}^2 \]

\[ = \left( \frac{2\alpha_1}{c_k} - \frac{k_4c_4\sqrt{c_\theta}}{\alpha_5Da} \right)||\nabla U^1_j - \nabla U^2_j||_{\Omega}^2. \tag{3.36} \]

To reach (3.36), we have applied Hölder’s, Poincare’s and Sobolev’s inequalities and Lipschitz continuous property of $K$. Thus, if \( \frac{2\alpha_1}{c_k} > \frac{k_4c_4\sqrt{c_\theta}}{\alpha_5Da} \), then $B$ is elliptic with $c = \left( \frac{2\alpha_1}{c_k} - \frac{k_4c_4\sqrt{c_\theta}}{\alpha_5Da} \right)$.

**Lemma 4.** The non-linear operator $A$ as in (3.31) is continuous from $H^1_0(\Omega)^d$ to $H^{-1}(\Omega)^d$.

**Proof.** Let $\mathbf{u}_n^1 \to \mathbf{u}_1$ in $H^1_0(\Omega)^d$ as $n \to \infty$. Consider

\[ ||(A\mathbf{u}_n^1 - A\mathbf{u}_1, Z)|| \leq 2\alpha_1||D(U^1_n) - D(U_1)||_{\Omega}||D(Z)||_{\Omega} \]

\[ + \alpha_2||\nabla \cdot U^1_n - \nabla \cdot U_1||_{\Omega}||\nabla \cdot Z||_{\Omega} + \frac{1}{Da}||K(U^1_n) - K(U_1)||_{L^2(\Omega)}||\mathbf{v}_j||_{L^2(\Omega)}||Z||_{L^2(\Omega)} \]

On applying Lipschitz continuity of $K$ and Sobolev inequality, we find

\[ ||A\mathbf{u}_n^1 - A\mathbf{u}_1||_{H^{-1}(\Omega)^d} \leq 2\alpha_1||D(U^1_n) - D(U_1)||_{\Omega} + \alpha_2||\nabla \cdot U^1_n - \nabla \cdot U_1||_{\Omega} \]

\[ + \frac{k_4c_4\sqrt{c_\theta}}{Da}||U^1_n - U_1||_{\Omega} \]

and $||A\mathbf{u}_n^1 - A\mathbf{u}_1||_{H^{-1}(\Omega)^d} \to 0$ as $n \to \infty$. That is, $A$ is continuous.

**Theorem 3.5.** Suppose that assumptions (A), (B) and (C) hold. Further, if the given data and non-dimensional parameters satisfy the following assumption

\[ \frac{2\alpha_1}{c_k} > \frac{k_4c_4\sqrt{c_\theta}}{\alpha_5Da}, \tag{3.37} \]

then for a given pair $(\mathbf{v}_j, P) \in H^1(\Omega)^d \times L^2(\Omega)^d$, the problem $(Q_{u_2}(\mathbf{u}_1))$ has a unique solution $\mathbf{u}_1 \in H^1_0(\Omega)^d$. Moreover, if

\[ \frac{2\alpha_1}{c_k} > \frac{k_4\sqrt{c_\theta}\alpha_4}{\alpha_3Da}, \tag{3.38} \]
holds, then $U_s$ satisfies the following a priori estimate

$$
\|\nabla U_s\|_{0,\Omega} \leq \frac{1}{\left(\frac{2\alpha_4}{\alpha_3} - \frac{b_2\sqrt{\alpha_4}}{\alpha_3}d\right)} \left(\frac{\phi_4\alpha_4}{\alpha_3} + \sqrt{c_p}\|b_s\|_{0,\Omega}\right).
$$

(3.39)

**Proof.** The analysis shown in Lemmas 3 and 4 justifies that $A$ satisfies the hypothesis of the Browder-Minty theorem (see Theorem A.3, Appendix A). Consequently, the operator Equation (3.32) or the problem (3.28) has a unique solution $U_s \in H^1_0(\Omega)^d$ for any given pair $(V_f, P) \in H^1(\Omega)^d \times L^2(\Omega)$. Further, if (3.38) holds, then $U_s$ satisfies the apriori estimate (3.39). Indeed, from (3.28) replacing $Z = U_s$ and using Poincare’s inequality, we have

$$
B(U_s, U_s) = L(U_s) \leq (\phi_4\|P\|_{0,\Omega} + \sqrt{c_p}\|b_s\|_{0,\Omega})\|\nabla U_s\|_{0,\Omega}
$$

Making use of the definition of $B(U_s, U_s)$ and Korn’s, Hölder’s and Sobolev inequalities and boundedness property of $K$, we obtain

$$
\|\nabla U_s\|_{0,\Omega} \leq \frac{1}{\left(\frac{2\alpha_4}{\alpha_3} - \frac{b_2\sqrt{\alpha_4}}{\alpha_3}d\right)} \left(\frac{\phi_4\alpha_4}{\alpha_3} + \sqrt{c_p}\|b_s\|_{0,\Omega}\right).
$$

The analysis in Subsections 3.4–3.5 describes the existence and uniqueness of problems $(Q_{w_1}(\varsigma)) - (Q_{w_2}(U_s))$. In the next subsections, we focus on developing existence and uniqueness results corresponding to $(Q_{w_1}(\nabla \cdot \varsigma)) - (Q_{w_2}(\nabla \cdot U_s))$ that is the case (b).

3.6 Case (b): existence and uniqueness of a solution to $(Q_{w_1}(\nabla \cdot \varsigma))$

Analysis in this subsection is analogous to the arguments in the Subsection 3.4. Thus, we only state the main theorem and omit the proof.

**Theorem 3.6.** Suppose that the assumptions (A) and (B) hold. Then for a given $\varsigma \in H^1_0(\Omega)^d$, the problem $(Q_{w_1}(\nabla \cdot \varsigma))$ has a unique solution $(V_f, P) \in \mathbb{Y} = H^1(\Omega)^d \times L^2(\Omega)$ that depends continuously on the given data. Moreover, the solution $(V_f, P)$ satisfies the following a priori bound

$$
\|V_f\|_{1,\Omega}^2 + \|P\|_{0,\Omega}^2 \leq \left(\frac{\alpha_4}{\alpha_3}\right)^2.
$$

(3.40)

**Proof.** Proof of this theorem follows from Theorem 3.3 and Proposition 3.4.

3.7 Case (b): existence and uniqueness of a solution to $(Q_{w_2}(\nabla \cdot U_s))$

We note that $K(\nabla \cdot U_s)$ is a non-linear function of $\nabla \cdot U_s$ (see assumption (A4) in Subsection 1.2) which makes $(Q_{w_2}(\nabla \cdot U_s))$ a semilinear problem.

By introducing a semilinear form $B(\cdot, \cdot): H^1_0(\Omega)^d \times H^1_0(\Omega)^d \to \mathbb{R}$ that is given by

$$
B(U_s, Z) = 2\alpha_1(D(U_s) : D(Z)) + \alpha_2(\nabla \cdot U_s, \nabla \cdot Z) - \frac{1}{Da}(K(\nabla \cdot U_s)V_f, Z)_{\Omega}
$$

(3.41)

and a linear form $L: H^1_0(\Omega)^d \to \mathbb{R}$ defined as

$$
L(Z) = \phi_4(P, \nabla \cdot Z)_{\Omega} + (b_s, Z)_{\Omega},
$$

(3.42)

weak problem $(Q_{w_2}(\nabla \cdot U_s))$ can be rewritten as an abstract formulation. For a given pair $(V_f, P) \in H^1(\Omega)^d \times L^2(\Omega)$, find $U_s \in H^1_0(\Omega)^d$ such that

$$
B(U_s, Z) = L(Z) \text{ for all } Z \in H^1_0(\Omega)^d.
$$

(3.43)
Similar to Subsection 3.5 to show existence and uniqueness results for problem (3.43), we will use the Browder-Minty theorem (see Theorem A.3, Appendix A), which is based on the monotone operator approach. We state the main theorem without proof, which can be done similarly to the proof of Theorem 3.5.

**Theorem 3.7.** Suppose that assumptions (A), (B) and (C) hold. Further, if the given data and non-dimensional parameters satisfy the following assumption

\[
\frac{2\alpha_1}{c_k} > \frac{k_s\alpha_d}{\alpha_3 Da},
\]

then for a given pair \((V_f, P) \in H^1(\Omega)^d \times L^2(\Omega)^d\), the problem \((Q_{w_2}(\nabla \cdot U_s))\) has a unique solution \(U_s \in H^1_0(\Omega)^d\). Moreover, if

\[
\frac{2\alpha_1}{c_k} > \frac{k_s\sqrt{c_p} \alpha_d}{\alpha_3 Da}
\]

holds, then \(U_s\) satisfies the following a priori estimate

\[
||\nabla U_s||_{0, \Omega} \leq \frac{1}{\left(\frac{2\alpha_1}{c_k} - \frac{k_s\sqrt{c_p} \alpha_d}{\alpha_3 Da}\right)} \left(\frac{\phi_d \alpha_d}{\alpha_3} + \sqrt{c_p} ||b_s||_{0, \Omega}\right).
\]

**Proof.** The proof of this theorem can be done similarly to the proof of Theorem 3.5. The analysis in Subsections 3.6–3.7 completes the existence and uniqueness of solution to problem \((Q_{w_1}(\nabla \cdot \zeta) - (Q_{w_2}(\nabla \cdot U_s))\). In the next section, we focus on the development of existence and uniqueness results corresponding to coupled non-linear problems \((Q_{w_1}(U_s)) - (Q_{w_2}(U_s))\) and \((Q_{w_1}(\nabla \cdot U_s)) - (Q_{w_2}(\nabla \cdot U_s))\), respectively, by converting them into a fixed-point problem.

### 4. Case (a): reduction to a fixed-point problem for \((Q_{w_1}(U_s)) - (Q_{w_2}(U_s))\)

We note that for a given \(\zeta \in H^1_0(\Omega)^d\), the problem \((Q_{w_1}(\zeta))\) has a unique solution \((V_f, P) \in H^1(\Omega)^d \times L^2(\Omega)^d\) (see Subsection 3.4). Consequently, we can define a mapping \(T_1 : H^1_0(\Omega)^d \to H^1(\Omega)^d \times L^2(\Omega)^d\) such that \(T_1(\zeta) = (V_f, P)\). Further, for a given pair \((V_f, P) \in H^1(\Omega)^d \times L^2(\Omega)^d\), the problem \((Q_{w_2}(U_s))\) has a unique solution \(U_s \in H^1_0(\Omega)^d\) (see Subsection 3.5). Therefore, we can define a mapping \(T_2 : H^1(\Omega)^d \times L^2(\Omega) \to H^1_0(\Omega)^d\) such that \(T_2(V_f, P) = U_s\). Now, in order to get the fixed-point problem corresponding to \((Q_{w_1}(U_s)) - (Q_{w_2}(U_s))\), we define a composition map \(T = T_2 \circ T_1 : H^1(\Omega)^d \to H^1_0(\Omega)^d\) such that

\[
T(\zeta) = (T_2 \circ T_1)(\zeta) = T_2(T_1(\zeta)) = T_2(V_f, P) = U_s.
\]

Thus, a fixed-point of mapping \(T\) solves the coupled non-linear problem \((Q_{w_1}(U_s)) - (Q_{w_2}(U_s))\) or equivalently, (3.3)–(3.5) when \(\zeta = U_s\). In order to show that the mapping \(T\) has a fixed point, we use Schauder’s fixed-point theorem (see Theorem A.2, Appendix A).\(^2\) Thus, in the following analysis, we prove some results in the form of lemmas to verify the hypotheses of Schauder’s fixed-point theorem.

#### 4.1 Analysis of the fixed-point problem

Throughout this subsection, we assume that hypotheses of Theorem 3.3, Proposition 3.4 and Theorem 3.5 hold. Then, we have

**Lemma 5.** Given \(r > 0\), let \(W_r\) be a closed and convex subset of \(H^1(\Omega)^d\) defined by

\[
W_r = \{ w \in H^1_0(\Omega)^d : ||w||_{H^1(\Omega)^d} = ||\nabla w||_{0, \Omega} \leq r \},
\]

\(^2\)For the fixed-point approach, we are inspired by the working techniques used in [38, 39].
and assume that the data satisfies
\[
\frac{1}{\left(\frac{2a_1}{c_1} - \frac{k_2\sqrt{\pi\alpha_4}}{a_1D}\right)} \left(\frac{\alpha_4}{\alpha_3} + \sqrt{c_p}\|b_i\|_{0,\Omega}\right) \leq r. \tag{4.2}
\]
Then, \(T(W_r) \subseteq W_r\).

**Proof.** For any \(w \in W_r\), using estimate (3.39), we find
\[
\|T(w)\|_{0,\Omega^d} = \|T_2(T_1(w))\|_{0,\Omega^d} = \|U_i\|_{0,\Omega^d} \leq \frac{1}{\left(\frac{2a_1}{c_1} - \frac{k_2\sqrt{\pi\alpha_4}}{a_1D}\right)} \left(\frac{\alpha_4}{\alpha_3} + \sqrt{c_p}\|b_i\|_{0,\Omega}\right). \tag{4.3}
\]
The above estimate (4.3) together with the assumption (4.2) imply \(T(w) \in W_r\), which proves \(T(W_r) \subseteq W_r\). \(\square\)

**Lemma 6.** The map \(T_1 : H^1_0(\Omega)^d \to H^1(\Omega)^d \times L^2(\Omega)\) satisfies
\[
\|T_1(\xi) - T_1(\bar{\xi})\|_\Omega \leq \frac{\sqrt{2k_i\alpha_4c_3}}{\alpha_3^2D}\|\xi - \bar{\xi}\|_{0,\Omega}. \tag{4.4}
\]

**Proof.** Given \(\xi, \bar{\xi} \in H^1_0(\Omega)^d\), let \((V_f, P), (\bar{V}_f, \bar{P}) \in H^1(\Omega)^d \times L^2(\Omega)\) be the corresponding solutions of \((Q_w, (\xi))\). Then, Equation (3.7) implies
\[
\langle \mathcal{H}_\xi(V_f, P), (W, q) \rangle = 0 \text{ for all } (W, q) \in \mathcal{Y}, \tag{4.5}
\]
Taking the difference between the above equations, we get
\[
\langle \mathcal{H}_\xi(V_f, P) - \mathcal{H}_{\bar{\xi}}(\bar{V}_f, \bar{P}), (W, q) \rangle = 0 \text{ for all } (W, q) \in \mathcal{Y}. \tag{4.6}
\]
Replacing \(W = V_f - \bar{V}_f\) and \(q = P - \bar{P}\) in the above equation and using the definition of \(\mathcal{H}_\xi\) and \(\mathcal{H}_{\bar{\xi}}\), we get
\[
2\|D(V_f) - D(\bar{V}_f)\|_{0,\Omega} + \lambda\|\nabla \cdot V_f - \nabla \cdot \bar{V}_f\|_{0,\Omega}^2 + a_0\|P - \bar{P}\|_{0,\Omega}^2
\]
\[
= -\frac{1}{Da}(K(\xi)(V_f - \bar{V}_f), V_f - \bar{V}_f) - \frac{1}{Da}((K(\xi) - K(\bar{\xi}))\bar{V}_f, V_f - \bar{V}_f). \tag{4.8}
\]
Using Korn’s, Hölder’s inequalities and estimate (3.23), we obtain
\[
\|V_f - \bar{V}_f\|_{1,\Omega}^2 + \|P - \bar{P}\|_{0,\Omega}^2 \leq \frac{\alpha_4}{\alpha_3^2Da}||K(\xi) - K(\bar{\xi})||_{0,\Omega}||V_f - \bar{V}_f||_{L^4(\Omega)}^2.
\]
Further, using Lipschitz continuous property of \(K\) and Sobolev’s inequality, we get
\[
\left(\|V_f - \bar{V}_f\|_{1,\Omega}^2 + \|P - \bar{P}\|_{0,\Omega}^2\right) \leq \frac{k_1\alpha_4c_3}{\alpha_3^2Da}||\xi - \bar{\xi}||_{0,\Omega}||V_f - \bar{V}_f||_{L^4(\Omega)}^2.
\]
or,
\[
\|V_f, P\) - (\bar{V}_f, \bar{P})\|_\mathcal{Y} = \left(\|V_f - \bar{V}_f\|_{1,\Omega}^2 + ||P - \bar{P}\|_{0,\Omega}^2\right)^{1/2} \leq \frac{\sqrt{2k_i\alpha_4c_3}}{\alpha_3^2Da}||\xi - \bar{\xi}||_{0,\Omega}. \tag{4.9}
\]
This establishes (4.4). \(\square\)

**Lemma 7.** The map \(T_2 : H^1(\Omega)^d \times L^2(\Omega) \to H^1_0(\Omega)^d\) satisfies
\[
\|T_2(V_f, P) - T_2(\bar{V}_f, \bar{P})\|_{0,\Omega^d} \leq \beta \left[\|P - \bar{P}\|_{0,\Omega} + \|V_f - \bar{V}_f\|_{1,\Omega}\right] \tag{4.10}
\]
where \(\beta = \left(\frac{1}{\frac{2a_1}{c_1} - \frac{k_2\sqrt{\pi\alpha_4}}{a_1D}}\right)\max \left\{\phi_\alpha, \frac{k_2\sqrt{\pi}}{Da}\right\}.\)
Proof. Given \((V_f, P), (\tilde{V}_f, \tilde{P}) \in H^1(\Omega)^d \times L^2(\Omega),\) let \(U_r, \tilde{U}_r \in H^1_0(\Omega)^d\) be the corresponding solutions of \((Q_{w_2}(U_r)).\) Then, (3.28) implies

\[
B(U_r, Z) = L(Z) \text{ for all } Z \in H_0^1(\Omega)^d, \tag{4.11}
\]

\[
B(\tilde{U}_r, Z) = L(Z) \text{ for all } Z \in H_0^1(\Omega)^d. \tag{4.12}
\]

Taking the difference between the above equations, we get

\[
2\alpha_1(D(U_r) - D(\tilde{U}_r)) : D(Z)_\Omega + \alpha_2(\nabla \cdot U_r - \nabla \cdot \tilde{U}_r, \nabla \cdot Z)_\Omega
= \phi_r|P - \tilde{P}, \nabla \cdot Z|_\Omega + \frac{1}{Da}(|K(U_r)(V_f - \tilde{V}_f), Z|_\Omega
+ \frac{1}{Da}|(K(U_r) - K(\tilde{U}_r))\tilde{V}_f, Z|_\Omega.
\]

Replace \(Z = U_r - \tilde{U}_r\) and using Cauchy-Schwarz and Hölder’s inequalities, we get

\[
2\alpha_1||D(U_r) - D(\tilde{U}_r)||_{L^2(\Omega)}^2 + \alpha_2||\nabla \cdot U_r - \nabla \cdot \tilde{U}_r||_{L^2(\Omega)}^2 \leq \phi_r||P - \tilde{P}||_{L^2(\Omega)}||\nabla \cdot (U_r - \tilde{U}_r)||_{L^2(\Omega)}
+ \frac{1}{Da}||K(U_r)||_{L^\infty(\Omega)}||V_f - \tilde{V}_f||_{L^2(\Omega)}||U_r - \tilde{U}_r||_{L^2(\Omega)}
+ \frac{1}{Da}||K(U_r) - K(\tilde{U}_r)||_{L^2(\Omega)}||\tilde{V}_f||_{L^2(\Omega)}||U_r - \tilde{U}_r||_{L^2(\Omega)}.
\]

Moreover, using Lipschitz property of \(K,\) Korn’s, Poincare’s and Sobolev’s embedding inequalities and estimate (3.23), we get

\[
||T_2(V_f, P) - T_2(\tilde{V}_f, \tilde{P})||_{H^1_0(\Omega)^d} = ||U_r - \tilde{U}_r||_{H^1_0(\Omega)^d} = ||\nabla U_r - \nabla \tilde{U}_r||_{L^2(\Omega)}
\leq \frac{1}{(2\alpha_1 \frac{1}{\alpha_2} - \frac{k_2 \sqrt{\gamma_0}}{\alpha_3 Da})} \left[ \phi_r||P - \tilde{P}||_{L^2(\Omega)} + \frac{k_2 \sqrt{\gamma_0}}{Da}||V_f - \tilde{V}_f||_{L^2(\Omega)} \right],
\]

or,

\[
||T_2(V_f, P) - T_2(\tilde{V}_f, \tilde{P})||_{H^1_0(\Omega)^d} \leq \beta \left[ ||P - \tilde{P}||_{L^2(\Omega)} + ||V_f - \tilde{V}_f||_{L^2(\Omega)} \right] \tag{4.13}
\]

where \(\beta = \left( \frac{1}{(2\alpha_1 \frac{1}{\alpha_2} - \frac{k_2 \sqrt{\gamma_0}}{\alpha_3 Da})} \right) \max \left\{ \phi_r, \frac{k_2 \sqrt{\gamma_0}}{Da} \right\}.\)

Lemma 8. The map \(T = T_2 \circ T_1 : H^1_0(\Omega)^d \subset L^2(\Omega)^d \rightarrow H^1_0(\Omega)^d\) satisfies

\[
||T(\zeta) - T(\tilde{\zeta})||_{H^1_0(\Omega)^d} \leq \frac{2\beta k_1 \alpha_4 c_0}{\alpha_3 Da} ||\zeta - \tilde{\zeta}||_{L^2(\Omega)} \leq \frac{2\beta k_1 \alpha_4 c_0 \sqrt{\gamma_0}}{\alpha_3 Da} ||\nabla \zeta - \nabla \tilde{\zeta}||_{L^2(\Omega)} \tag{4.14}
\]

Proof. From (4.13), we have

\[
||T(\zeta) - T(\tilde{\zeta})||_{H^1_0(\Omega)^d} = ||T_2(V_f, P) - T_2(\tilde{V}_f, \tilde{P})||_{H^1_0(\Omega)^d}
\leq \beta \left[ ||P - \tilde{P}||_{L^2(\Omega)} + ||V_f - \tilde{V}_f||_{L^2(\Omega)} \right] \tag{4.15}
\]

We achieve (4.14) with the help of (4.9) and (4.15). \(\Box\)

Theorem 4.1. The mapping \(T : W_r \subset H^1_0(\Omega)^d \rightarrow W_r \subset H^1_0(\Omega)^d\) is continuous and \(\overline{T(W_r)}\) is compact.

Proof. The continuity of \(T\) follows in a straightforward manner from (4.14). Now, given a sequence \(\{\zeta_k\}_{k \in \mathbb{N}}\) of \(W_r\), which is clearly bounded, there exists a sub-sequence \(\{\zeta_{k_l}\}_{l \in \mathbb{N}}\) and \(\zeta \in H^1_0(\Omega)^d\) such that \(\zeta_{k_l} \rightharpoonup \zeta\) in \(H^1_0(\Omega)^d\). In this way, thanks to the compact embedding of \(H^1_0(\Omega)^d\) in \(L^2(\Omega)^d\), which implies \(\zeta_{k_l} \rightharpoonup \zeta\) in \(L^2(\Omega)^d\), which combined with (4.14) implies that \(T(\zeta_{k_l}) \rightarrow T(\zeta)\). This proves that \(\overline{T(W_r)}\) is compact. \(\Box\)
**Theorem 4.2.** Suppose that the hypotheses of Theorem 3.3, Proposition 3.4 and Theorem 3.5 hold. Then, the mapping $T$ defined in 4.1 has a fixed point $U_2 \in H^1_0(\Omega)^d$, which in turn implies that coupled problem $(Q_{w_1}(U_1)) - (Q_{w_2}(U_1))$ has a solution $(V_f, P) \in H^1(\Omega)^d \times L^2(\Omega)$ and $U_2 \in H^1_0(\Omega)^d$. Further, if

$$\frac{2\beta k_\ell \alpha_c c_\ell \sqrt{c_p}}{\alpha^\ell Da} < 1$$

(4.16)

then $T$ has a unique fixed point $U_2 \in H^1_0(\Omega)^d$, which in turn implies that coupled problem $(Q_{w_1}(U_1)) - (Q_{w_2}(U_1))$ has a unique solution $(V_f, P) \in H^1(\Omega)^d \times L^2(\Omega)$ and $U_2 \in H^1_0(\Omega)^d$.

**Proof.** The above Theorem 4.1 implies that $T$ satisfies all hypotheses of Schauder’s fixed-point theorem (see Thereom A.2, Appendix A). Consequently, the mapping $T$ has a fixed-point $U_2 \in H^1_0(\Omega)$. This implies that coupled problem $(Q_{w_1}(U_1)) - (Q_{w_2}(U_1))$ or equivalently, (3.3)–(3.5) when $\zeta = U_2$ has a solution $(V_f, P) \in H^1(\Omega)^d \times L^2(\Omega)$ and $U_2 \in H^1_0(\Omega)^d$. Further, if (4.12) is true, then $T : W_r \rightarrow W_r$ is a strict contraction mapping. That implies $T$ has a unique fixed point $U_2 \in H^1_0(\Omega)^d$ due to Banach’s fixed-point theorem (see p. 415 [34]). This implies that coupled problem $(Q_{w_1}(U_1)) - (Q_{w_2}(U_1))$ or equivalently, (3.3)–(3.5) when $\zeta = U_2$ has a unique solution $(V_f, P) \in H^1(\Omega)^d \times L^2(\Omega)$ and $U_2 \in H^1_0(\Omega)^d$. □

**Remark 4.3** (Continuous dependence). If the non-dimensional parameters and constants satisfy the following assumption

$$2\alpha^* Da > \frac{k_\ell \alpha_c c_\ell}{\alpha_3}, \quad 4\alpha_1 Da > \left( \frac{c_p k_1^2}{k_1} + \frac{k_\ell \alpha_c c_\ell (c_p + 2\sqrt{c_p})}{\alpha_3} \right), \quad 2\alpha_2 > \frac{\phi^2_s}{a_0},$$

(4.17)

where $\alpha^* = \frac{1}{c_\ell} \min\{2, \frac{1}{2\alpha_1 Da}\}$. Then, the continuous dependence (3.25) holds. Indeed, we have

\[
\begin{align*}
||V_f - V^*_f||_{L^2(\Omega)}^2 + ||\nabla(V^*_f - U^*_2)||_{L^2(\Omega)}^2 + ||P^* - P^2||_{L^2(\Omega)}^2 & \leq \frac{1}{\alpha_6^0} \left( ||b_{f,1}^* - b_{f,1} ||_{L^2(\Omega)} + \frac{\sqrt{c_p}}{2} ||T_{\alpha_1} - T_{\alpha_2}||_{L^2(\Omega)} \right)^2 + ||a_{0,1} - a_{0,2}||_{L^2(\Omega)}^2 + c_p ||b_{s,1} - b_{s,2}||_{L^2(\Omega)}^2,
\end{align*}
\]

(4.18)

where $\alpha_5 = \min \left\{ \alpha^* - \frac{4\alpha_1 Da}{2\alpha_1 Da}, \frac{2\alpha_1}{\alpha_1 Da} - \frac{c_p k_1^2}{2\alpha_1 Da}, \frac{2\alpha_1 Da}{\alpha_1 Da} \right\}$.

5. Case (b): reduction to a fixed-point problem to $(Q_{w_1}(V \cdot U_2)) - (Q_{w_2}(V \cdot U_2))$

We note that for a given $\zeta \in H^1_0(\Omega)^d$, the problem $(Q_{w_1}(V \cdot \zeta))$ has a unique solution $(V_f, P) \in H^1(\Omega)^d \times L^2(\Omega)$ (see Subsection 3.6). Consequently, we can define a mapping $T_1 : H^1_0(\Omega)^d \rightarrow H^1(\Omega)^d \times L^2(\Omega)$ such that $T_1(\zeta) = (V_f, P)$. Further, for a given pair $(V_f, P) \in H^1(\Omega)^d \times L^2(\Omega)$, the problem $(Q_{w_1}(V \cdot U_2))$ has a unique solution $U_2 \in H^1_0(\Omega)^d$ (see Subsection 3.7). Therefore, we can define a mapping $T_2 : H^1(\Omega)^d \times L^2(\Omega) \rightarrow H^1_0(\Omega)^d$ such that $T_2(V_f, P) = U_2$. Now, in order to get the fixed-point problem corresponding to $(Q_{w_1}(\nabla \cdot U_2)) - (Q_{w_2}(\nabla \cdot U_2))$, we define a composition map $T = T_2 \circ T_1 : H^1_0(\Omega)^d \rightarrow H^1_0(\Omega)^d$ such that

$$T(\zeta) = T_2(T_1(\zeta)) = T_2(V_f, P) = U_2.$$

(5.1)

Thus, a fixed-point of mapping $T$ solves the coupled non-linear problem $(Q_{w_1}(\nabla \cdot U_2))$ and $(Q_{w_2}(\nabla \cdot U_2))$ or equivalently, (3.3)–(3.5) when $\zeta = \nabla \cdot U_2$. In order to show that the mapping $T$ has a fixed point, we use Schauder’s fixed-point theorem (see Thereom A.2, Appendix A). Thus, in the following analysis, we state some results in the form of lemmas to verify the hypotheses of Schauder’s fixed-point theorem. The proof of the following results is almost similar to the proof presented in Subsection 4.1, so we omit the details.
5.1 Analysis of the fixed-point problem

Throughout this subsection, we assume that hypotheses of Theorems 3.6 and 3.7 hold. Then, we have

Lemma 9. Given $r > 0$, let $W_r$ be a closed and convex subset of $H^1(\Omega)^d$ defined by

$$W_r = \{ w \in H^1_0(\Omega)^d : \| w \|_{H^1_0(\Omega)^d} = \| \nabla w \|_{0, \Omega} \leq r \}$$

and assume that the data satisfy

$$\frac{1}{(2\alpha_1 c_k - \frac{k_2 \sqrt{\pi} c_k}{\alpha_3 D_a})} \left( \frac{\phi_i \alpha_4}{\alpha_3} + \sqrt{c_p} \| b_i \|_{0, \Omega} \right) \leq r. \quad (5.2)$$

Then, $T(W_r) \subseteq W_r$.

Proof. This lemma is proved similar to Lemma 5.

Lemma 10. The map $T_1 : H^1_0(\Omega)^d \to H^1(\Omega)^d \times L^2(\Omega)$ satisfies

$$\| T_1(\zeta) - T_1(\tilde{\zeta}) \|_V \leq \frac{\sqrt{2} k_1 \alpha_4 c_i}{\alpha_3^2 D_a} \| \nabla \cdot \zeta - \nabla \cdot \tilde{\zeta} \|_{0, \Omega}. \quad (5.3)$$

(see Lemma 3.1 for the definition of the space $V$).

Proof. This lemma is proved similar to Lemma 6.

Lemma 11. The map $T_2 : H^1(\Omega)^d \times L^2(\Omega) \to H^1_0(\Omega)^d$ satisfies

$$\| T_2(V_j, P) - T_2(\tilde{V}_j, \tilde{P}) \|_{H^1_0(\Omega)^d} \leq \tilde{\beta} \left[ \| P - \tilde{P} \|_{0, \Omega} + \| V_j - \tilde{V}_j \|_{1, \Omega} \right], \quad (5.4)$$

where $\tilde{\beta} = \left( \frac{1}{\alpha_3^2} - \frac{2 k_2 \sqrt{\pi} c_k}{\alpha_3 D_a} \right) \max \{ \phi_i, \frac{k_2 \sqrt{\pi} c_k}{D_a} \}$.

Proof. This lemma is proved similar to Lemma 7.

Lemma 12. The map $T = T_2 \circ T_1 : H^1_0(\Omega)^d \to H^1_0(\Omega)^d$ satisfies

$$\| T(\zeta) - T(\tilde{\zeta}) \|_{H^1_0(\Omega)^d} \leq \frac{2 \tilde{\beta} k_1 \alpha_4 c_i}{\alpha_3^2 D_a} \| \nabla \cdot \zeta - \nabla \cdot \tilde{\zeta} \|_{0, \Omega} \leq \frac{2 \tilde{\beta} k_1 \alpha_4 c_i}{\alpha_3^2 D_a} \| \nabla \zeta - \nabla \tilde{\zeta} \|_{0, \Omega}. \quad (5.5)$$

Proof. This lemma is proved similar to Lemma 8.

Theorem 5.1. Suppose that the hypotheses of Theorems 3.6 and 3.7 hold and if the following assumption

$$\frac{2 \tilde{\beta} k_1 \alpha_4 c_i}{\alpha_3^2 D_a} < 1 \quad (5.6)$$

holds then $T$ has a unique fixed point $U_\epsilon \in H^1_0(\Omega)^d$, which in turn implies that coupled problem $(Q_{\alpha_1}(\nabla \cdot U_\epsilon)) - (Q_{\alpha_2}(\nabla \cdot U_\epsilon))$ has a unique solution $(V_j, P) \in H^1(\Omega)^d \times L^2(\Omega)$ and $U_\epsilon \in H^1_0(\Omega)^d$.

Proof. If $\frac{2 \tilde{\beta} k_1 \alpha_4 c_i}{\alpha_3^2 D_a} < 1$, then Lemma 12 implies $T : W_r \subset H^1_0(\Omega)^d \to W_r \subset H^1_0(\Omega)^d$ is a strict contraction mapping. That implies $T$ has a unique fixed point $U_\epsilon \in H^1_0(\Omega)^d$ due to Banach’s fixed-point theorem. That means the coupled problem $(Q_{\alpha_1}(\nabla \cdot U_\epsilon)) - (Q_{\alpha_2}(\nabla \cdot U_\epsilon))$ or equivalently, the problem (3.3)–(3.5) with $\zeta = \nabla \cdot U_\epsilon$ has a unique solution $(V_j, P) \in H^1(\Omega)^d \times L^2(\Omega)$ and $U_\epsilon \in H^1_0(\Omega)^d$.

Remark 5.2.

- If the non-dimensional parameters and the constants satisfy the following constraints

$$2\alpha^2 D_a > \frac{k_1 c_i \alpha_4}{\alpha_3}, \quad \frac{4 \alpha_1 D_a}{c_k} > \left( \frac{c_i k_2}{k_1} + \frac{3 k_1 c_i \alpha_4}{\alpha_3} \right), \quad 2\alpha_2 \geq \frac{\phi^2_\epsilon}{\alpha_0}. \quad (5.7)$$
Since there exists a constant uniformly positive definite, bounded operators, non-linear structures of the hydraulic resistivity. We approximate the operators \( \varsigma \) for case (a) and case (b) \( \varsigma = U_j \) and \( \varsigma = \nabla \cdot U_j \). Instead of boundedness property (ii) of (3.1), we assume there exists a constant \( k_0 > 0 \), such that following sub-linear growth condition holds

\[
||K(x)|| \leq k_0(1 + ||x||) \text{ for all } x \in \mathbb{R}^d.
\]  

(6.1)

The above growth condition yields for case (a)

\[
||K(U_j)||_{0,\Omega} \leq \sqrt{2k_0(\sqrt{||\Omega||} + ||U_j||_{0,\Omega})}.
\]  

(6.2)

We have the following result for case (a).

**Theorem 6.1.** Assume that the data and parameters satisfy the assumption (A), (i) of (3.1) and (3.2), (3.37), (3.38) and \( K \) satisfy the growth condition (6.2). Further, if the following parameter constraint

\[
\frac{2\alpha_1}{c_k} > \sqrt{2c_p c_k k_0 \alpha_4} \frac{\alpha_4}{\alpha_3} D_a
\]  

(6.3)

is satisfied, then (3.3)–(3.5) together with \( \varsigma = U_j \) has a solution \( (V_f, U_j, P) \in H^1(\Omega)^d \times H_0^1(\Omega)^d \times L^2(\Omega) \) such that

\[
|||V_f, P)||_\Gamma \leq \frac{\alpha_4}{\alpha_3}
\]  

(6.4)

and

\[
||\nabla U_j||_{0,\Omega} \leq \frac{1}{\left(\frac{2\alpha_1}{c_k} - \sqrt{2c_p c_k k_0 \alpha_4} \frac{\alpha_4}{\alpha_3} D_a \right)} \left[ \sqrt{c_p} ||b_j||_{0,\Omega} + \frac{\alpha_4}{\alpha_3} \left( \phi + \frac{\sqrt{||\Omega||} c_k k_0}{D_a} \right) \right]
\]  

(6.5)

where \( |\Omega| \) denotes the area or volume of the domain \( \Omega \).

**Proof.** We are inspired by the working techniques from [28]. Here, we are dealing with particular non-linear structures of the hydraulic resistivity. We approximate the operators \( K \) with a sequence of uniformly positive definite, bounded operators, \( \{K^m\}_{m \geq 1} \) defined by

\[
K_j^m(U_j) := \min (m, K_j(U_j)), \text{ for all } m \in \mathbb{N}.
\]  

(6.6)

Since \( K^m \) is bounded for each \( m \), Theorem 4.2 implies that there exists a triplet \( (V_f^m, U_j^m, P^m) \in H^1(\Omega)^d \times H_0^1(\Omega)^d \times L^2(\Omega) \) such that

\[
2(D(V_f^m) : D(W)_\Omega + \lambda(\nabla \cdot V_f^m, \nabla \cdot W)_\Omega - \phi_f(P^m, \nabla \cdot W)_\Omega \\
+ \frac{1}{Da} (K^m(U_j^m) V_f^m, W)_\Omega + \phi_f(\nabla \cdot V_f^m, q)_\Omega + a_0(P^m, q)_\Omega \\
= (b_j, W)_\Omega + (T_\infty, W)_\Omega + (a_0, q)_\Omega,
\]  

(6.7)

\[
2\alpha_1(D(U_j^m) : D(Z)_\Omega + \alpha_2(\nabla \cdot U_j^m, \nabla \cdot Z)_\Omega = \phi_f(P^m, \nabla \cdot Z)_\Omega \\
+ \frac{1}{Da} (K^m(U_j^m) V_f^m, Z)_\Omega + (b_j, Z)_\Omega.
\]  

(6.8)
We desire a uniform bound for the sequence \( \{(V^n_m, U^n_m, P^n_m)\} \), which is independent of \( m \). In order to do so, replace \((W, q)\) by \((V^n_m, P^n_m)\) in (6.7). Using the positive definiteness of \( K^n \) and the Cauchy-Schwarz, trace, Korn’s inequalities, we get the following estimate

\[
\| (V^n_m, P^n_m) \|_\gamma \leq \frac{\alpha_4}{\alpha_3}.
\] (6.9)

One can observe the right-hand side of (6.9) is independent of \( m \). Next, replacing \( Z \) by \( U^n_m \) in (6.8) and use Hölder’s, Poincare’s, Korn’s, Sobolev inequalities and (6.1), to get

\[
\frac{2\alpha_1}{c_k} \| \nabla U^n_m \|_{0, \Omega} \leq \sqrt{c_p} \| b_s \|_{0, \Omega} \| \nabla V^n_m \|_{0, \Omega} + \phi_3 \| P^n_m \|_{0, \Omega} \| \nabla U^n_m \|_{0, \Omega} + \frac{1}{Da} \| K(U^n_m) \|_{0, \Omega} \| V^n_m \|_{L^4(\Omega)} \| U^n_m \|_{L^4(\Omega)}
\] (6.10)

The estimates (6.9) and (6.10) imply that \((V^n_m, U^n_m, P^n_m) \in H^1(\Omega)^d \times H^0_0(\Omega)^d \times L^2(\Omega)\) uniformly bounded for all \( m \geq 1 \). Hence, there exists a triplet \((V_f, U_f, P) \in H^1(\Omega)^d \times H^0_0(\Omega)^d \times L^2(\Omega)\) and a sub-sequence of \((V^n_m, U^n_m, P^n_m)\) (we denote by the same symbol) such that

\[
(V^n_m, U^n_m, P^n_m) \to (V_f, U_f, P) \text{ weakly in } H^1(\Omega)^d \times H^0_0(\Omega)^d \times L^2(\Omega),
\] (6.11)

and the compact embedding \( H^1(\Omega)^d \hookrightarrow L^4(\Omega)^d \) yields

\[
(V^n_m, U^n_m) \to (V_f, U_f) \text{ strongly in } L^4(\Omega)^d \times L^4(\Omega)^d.
\] (6.12)

We seek to pass the limit in (6.7)–(6.8) as \( m \to \infty \). We observe that the weak convergence (6.11) is sufficient to pass the limit in the linear terms of (6.7)–(6.8); however, the non-linear terms demand strong convergence (6.12). Subsequently, the non-linear terms of the problem (6.7)–(6.8), which can be rewritten as

(i) for (6.7)

\[
\underbrace{(K^n(U^n_m) - K(U))}_\Omega V^n_m + (K(U))_\Omega (V^n_m - V_f) + (K(U))_\Omega W_f + (K(U))_\Omega W_f
\] (6.13)

(ii) for (6.8)

\[
\underbrace{(K^n(U^n_m) - K(U))}_\Omega V^n_m + (K(U))_\Omega (V^n_m - V_f) + (K(U))_\Omega Z_f + (K(U))_\Omega Z_f,
\] (6.14)

Since \( U^n_m \) converges to \( U_f \) strongly in \( L^2(\Omega)^d \), it implies \( U^n_m - U_f \to 0 \text{ a.e. in } \Omega \) up to a sub-sequence. The fact that \( K \) is Lipschitz guarantees that

\[
K^n(U^n_m) - K(U) \to 0 \text{ a.e. in } \Omega.
\] (6.15)

Indeed, we have

\[
|K^n(U^n_m) - K(U)| = |K^n(U^n_m)(x) - K^n(U)(x) + K^n(U)(x) + K(U)| \leq k_{\varepsilon} \| U^n_m - U \|_{\Omega} + |K^n(U)(x) - K(U)|.
\]

As \( U^n_m - U_f \to 0 \text{ a.e. in } \Omega \) together with the definition of the truncation function implies \( K^n(U^n_m) - K(U) \to 0 \text{ a.e. in } \Omega \). This establishes (6.15). Using the bound (6.9) and the convergence result (6.15), we get
Theorem 6.3. Assume that the data and parameters satisfy the assumption (A), (6.7)–(6.8) recovers (3.3)–(3.5) as
is satisfied, then (3.3)
Further, the solution is unique and subject to the following constraints

\[
\lim_{m \to \infty} ((\mathbf{K}^m(\mathbf{U}_m^m) - \mathbf{K}(\mathbf{U}_s))\mathbf{V}_m^m, \mathbf{W})_\Omega = 0, \quad \lim_{m \to \infty} ((\mathbf{K}^m(\mathbf{U}_m^m) - \mathbf{K}(\mathbf{U}_s))\mathbf{V}_m^m, \mathbf{Z})_\Omega = 0.
\]

The bound (6.10) together with estimate (6.2), and the strong convergence \( \mathbf{V}_m^m \to \mathbf{V}_f \) in \( L^q(\Omega)^d \) leads to

\[
\lim_{m \to \infty} (\mathbf{K}(\mathbf{U}_s)(\mathbf{V}_m^m - \mathbf{V}_f), \mathbf{W})_\Omega = 0, \quad \lim_{m \to \infty} (\mathbf{K}(\mathbf{U}_s)(\mathbf{V}_m^m - \mathbf{V}_f), \mathbf{Z})_\Omega = 0
\]

Thus, the terms with under braces in (6.13) and (6.14) tend to zero as \( m \to \infty \). Hence, we can say that (6.7)–(6.8) recovers (3.3)–(3.5) as \( m \to \infty \). This completes the proof of the Theorem 6.1.

Remark 6.2.

- We note that in the above case i.e. when \( \mathbf{K}(\mathbf{U}_s) \) is not bounded, however, satisfies the sub-linear growth condition (6.1), the uniqueness of solutions holds whenever the non-dimensional parameters and constants satisfy the following inequalities:

\[
\frac{2\alpha_1 Da}{c_s} > \left[ k_1 \sqrt{c_p \alpha_4} \alpha_3 + \sqrt{2}k_0(\sqrt{p} + \sqrt{c_p \alpha_7}) \right], \quad 2\alpha_2 \geq \frac{\phi_s^2}{\alpha_0},
\]

\[
\frac{4\alpha_2 Da}{c_k c_s} > \left[ \frac{3k_1 \sqrt{c_p \alpha_4} \alpha_3}{\alpha_4} + \sqrt{2}k_0(\sqrt{p} + \sqrt{c_p \alpha_7}) \right],
\]

where \( \alpha_7 = \left( \frac{1}{\alpha_2}, \frac{1}{\sqrt{c_p \alpha_4} \alpha_3} \right) \left( \alpha_4 + \frac{\phi_s^2}{\alpha_0} \right) \).

- In case (b) that is when \( \zeta = \nabla \cdot \mathbf{U}_s \), the sub-linear growth condition (6.1) becomes

\[
\| \mathbf{K}(\nabla \cdot \mathbf{U}_s) \|_{|\Omega|} \leq \sqrt{2}k_0(\sqrt{p} + \sqrt{c_p \alpha_7} + \| \nabla \cdot \mathbf{U}_s \|_{|\Omega|}).
\]

The specific structure \( \mathbf{K}(\nabla \cdot \mathbf{U}_s) = \| \gamma_{i} \nabla \cdot \mathbf{U}_s \|_{|\Omega|} \) falls under this case, and we can clearly see that \( \mathbf{K} \) satisfies (6.20). In this case, existence and uniqueness analysis can be developed based on similar lines as in Theorem 6.1. Indeed, we have the following theorem.

Theorem 6.3. Assume that the data and parameters satisfy the assumption (A), (i) of (3.1) and (3.2), (3.44), (3.45) and \( \mathbf{K} \) satisfy the growth condition (6.20). Further, if the following parameter constraint

\[
\frac{2\alpha_1}{c_k} > \sqrt{2} c_s k_0 \alpha_4 \alpha_3 Da
\]

is satisfied, then (3.3)–(3.5) together with \( \zeta = \nabla \cdot \mathbf{U}_s \) has a solution \( (\mathbf{V}_f, \mathbf{U}_s, P) \in H^1(\Omega)^d \times H^1_0(\Omega)^d \times L^2(\Omega) \) such that

\[
\| (\mathbf{V}_f, P) \|_U \leq \frac{\alpha_4}{\alpha_3}, \quad \| \nabla \mathbf{U}_s \|_{|\Omega|} \leq \alpha_8
\]

where \( |\Omega| \) denotes the area or volume of the domain \( \Omega \) and

\[
\alpha_8 = \frac{1}{\frac{2\alpha_1}{c_k} - \sqrt{2} c_s k_0 \alpha_4 \alpha_3 Da} \left[ \sqrt{c_p \| \mathbf{b}_s \|_{|\Omega|}} + \frac{\alpha_4}{\alpha_3} \left( \phi_s + \sqrt{2|\Omega|} \frac{c_s k_0}{Da} \right) \right].
\]

Further, the solution is unique and subject to the following constraints

\[
\frac{2\alpha_1 Da}{c_s} > \left[ \frac{k_1 \alpha_4}{\alpha_3} + \sqrt{2}k_0(\sqrt{p} + \alpha_8) \right], \quad 2\alpha_2 \geq \frac{\phi_s^2}{\alpha_0},
\]

\[
\frac{4\alpha_2 Da}{c_k c_s} > \left[ \frac{3k_1 \alpha_4}{\alpha_3} + \sqrt{2}k_0(\sqrt{p} + \alpha_8) \right].
\]

Proof. The proof of this theorem is similar to Theorem 6.1, we omit the details.

\[
\square
\]
### Table 1. Dimensionless poro-elasto-hydrodynamics parameters corresponding to tumour tissue with their value range.

| Dimensionless parameter | Range of values          | Supporting references |
|-------------------------|--------------------------|-----------------------|
| $Da$                    | $10^{-4} - 10^{-1}$      | [1, 30]               |
| $\alpha_t$             | $0 < \alpha_t \leq 10$  | [22]                  |
| $\varrho_t$            | $10^2 \leq \varrho_t \leq 10^3$ | [30]            |
| $\nu_p$                | $0.45 \leq \nu_p \leq 0.49$ | [31, 32]           |
| $\phi_t$               | $0.6 \leq \phi_t \leq 0.8$ | [1, 30]               |
| $K$                     | $0.00006 \leq K \leq 1.4$ | [30]                  |

#### 6.1 Comments on parameter restrictions

It may be noted that the existence and uniqueness of results (e.g. see Theorems 3.3, 3.5, 3.6, 3.7, 4.2, 5.1, 6.1 and 6.3, etc.) that are established in this work hold subject to certain parameter restrictions see e.g. (3.37), (3.38), (3.44), (3.45), (4.16), (4.17), (5.6), (5.7), (6.3), (6.18), (6.19), (6.21), (6.23) and (6.24) etc. Such a situation is typical in the case of multiphase mixture models where extra care needs to be paid to the physical admissibility of the parameters. See also Vromans et al. [29]. Further, some of the parameters in these inequalities do show a dependency on material properties of the tissue, like Poisson ratio, Young’s modulus etc. Thus, one has to ensure that these inequalities are satisfied simultaneously. This certainly depends on the choice of relevant parameters. We have collected data from the existing literature on parameters like $Da$, $\alpha_t$, $\varrho_t$ etc. which are relevant to biological tissues. We have then verified that there do exist parameter combinations within the given ranges in Table 1 that obey all the inequalities. This ensures that these assumptions (3.37), (3.38), (3.44), (3.45), (4.16), (4.17), (5.6), (5.7), (6.3), (6.18), (6.19), (6.21), (6.23) and (6.24) etc. can be interpreted from the point of view of various applications. We list the dimensionless poro-elasto-hydrodynamics parameters in Table 1. Further, we choose $\Omega$ as a d-dimensional ($d = 3$) sphere of unit radius (in dimension 1 mm) then $|\Omega| = \frac{4\pi}{3}$, $|\partial \Omega| = 4\pi$. We set $b_i = 0$, $i \in \{f, s\}$, $T_\infty = (1, 0, 0)$, and choose the numerical values for constants $c_i(\Omega) > 0$, $c_p(\Omega) > 0$, $c_i(\Omega, d) > 0$ as follows: $c_2 = 2$ (or $3$) for $H^1(\Omega)^d$ (or $H^1(\Omega)^d$) [33, 34] and $c_p = 1/2$, $c_i = 1/2 [35]$, $c_i = 2$ [34]. To verify the inequalities (3.37), (3.38), (3.44), (3.45), (4.16), (4.17), (5.6), (5.7), (6.3) and (6.21), we use the following combination of parameters from Table 1: $Da = 2 \times 10^{-2}$, $\alpha_t = 1$, $\varrho_t = 10^3$, $\nu_p = 0.45$, $k_i = 0.5$, $k_t = 1.4$, $\phi_t = 0.4$, $L_{Ap} = 1$, $k_t = 2 \times 10^{-3}$, and $0 < k_0 \leq 1$. Further, the restrictions (6.18), (6.19) and (6.23), (6.24), which ensure the uniqueness for arbitrary $K$, hold when we choose $Da = 10^{-1}$, and $k_0 = 10^{-2}$ with the remaining parameters as chosen above. Note that the choice of parameters mentioned above may not be unique; there could be other parameter combinations for which these restrictions hold true.

### 7. Summary

In this work, we have modelled the poro-elasto-hydrodynamics that mimic an in-vitro solid tumour using biphasic mixture theory. We simplified the generic biphasic mixture equations using certain assumptions based on the biological context and treated hydraulic resistivity as anisotropic, which depends on the deformation. This made our model non-linear and coupled. We derive an equivalent variational (or weak) formulation and developed existence and uniqueness results using the Galerkin method, monotone operator theory and fixed-point theory. The detailed analysis is done by considering two cases: (a) $K(\mathbf{\chi}) = K(\mathbf{U})$, (b) $K(\nabla \cdot \mathbf{\chi}) = K(\nabla \cdot \mathbf{U})$. In both cases, we first developed existence and uniqueness analysis for auxiliary linear and semilinear sub-problems using the Galerkin method and monotone operator theory. Then, we convert the corresponding coupled non-linear problem to the fixed-point problem in both cases. Further, to develop the existence of solutions for the corresponding fixed-point problems,
we used the Schauder fixed-point theorem. Uniqueness is assured via the Banach contraction theorem. For the case where $K$ is not bounded but satisfies the sub-linear growth condition, we have developed the existence and uniqueness results. Moreover, we have collected certain realistic ranges of parameters involved in the model and ensured that the theoretical restrictions derived by us are compatible with these parameter ranges.

**Acknowledgement.** We are grateful for the valuable constructive suggestions provided by the anonymous referees, which greatly enhanced the quality of our paper. In particular, we greatly appreciate the suggestions on alternative methodologies to prove one of the main results. M. Alam, one of the authors, is thankful to Dr. Michael Eden and Dr. Debajyoti Choudhuri for their input regarding the analysis.

**Competing interests.** The authors declare that there is no conflict of interest.

Appendix A

Function spaces and useful results: Let \( \Omega \) be a bounded, open subset of \( \mathbb{R}^d \), \( d = 2, 3 \). \( L^2(\Omega) \) is the space of all measurable functions \( u \) defined on \( \Omega \) for which

\[
\|u\|_{0,\Omega} = \left( \int_\Omega |u|^2 \, d\Omega \right)^{1/2} < +\infty,
\]

(A1)

In (A1), \( \| \cdot \|_{0,\Omega} \) defines a norm on \( L^2(\Omega) \). For any \( u = (u_1, u_2, \ldots, u_d) \in L^2(\Omega)^d \), \( \|u\|_{0,\Omega} \) is defined as

\[
\|u\|_{0,\Omega} = \left( \sum_{i=1}^d |u_i|^2 \, d\Omega \right)^{1/2},
\]

(A2)

and for any element \( K = (K_{ij})_{1\leq i\leq j\leq d} \in (L^2(\Omega))^{d \times d} \), we define the norm of \( K \) as

\[
\|K\|_{0,\Omega} = \left( \sum_{i=1}^d \sum_{j=1}^d |K_{ij}|^2 \, d\Omega \right)^{1/2}.
\]

(A3)

The symbols \( (\cdot,\cdot)_{\Omega} \), and \( (\cdot,\cdot)_{\partial\Omega} \) denote inner products in \( L^2(\Omega) \), \( L^2(\Omega)^d \), and \( (L^2(\Omega))^{d \times d} \) and in the corresponding trace spaces \( L^2(\partial\Omega) \), \( L^2(\partial\Omega)^d \), and \( (L^2(\partial\Omega))^{d \times d} \), respectively.

For any two functions \( u \) and \( v \), the inner products \( (\cdot,\cdot)_{\Omega} \), and \( (\cdot,\cdot)_{\partial\Omega} \) are defined as

\[
(u,v)_{\Omega} = \int_{\Omega} u \cdot v \, d\Omega, \quad (u,v)_{\partial\Omega} = \int_{\partial\Omega} u \cdot v \, d\sigma.
\]

The first-order Sobolev space is defined as \( H^1(\Omega)^d = \{u \in L^2(\Omega)^d | \nabla u \in (L^2(\Omega))^{d \times d} \} \) and the norm of a function \( u \in H^1(\Omega)^d \) is defined as

\[
\|u\|_{1,\Omega} = (\|u\|_{0,\Omega}^2 + \|\nabla u\|_{0,\Omega}^2)^{1/2},
\]

(A4)

3See [34] for function spaces and preliminaries.
$H_0^1(\Omega)^d$ denotes the space of functions in $H^1(\Omega)^d$ with zero trace. The dual space of $H_0^1(\Omega)^d$ is denoted by $H^{-1}(\Omega)^d$.

To show the existence of a solution, we rely on the following results.

**Lemma A.1.** (p.164 [36]) Let $X$ be a finite-dimensional Hilbert space with scalar product $\langle \cdot, \cdot \rangle$ and norm $|\cdot|$, and let $G$ be a continuous mapping from $X$ into itself such that

$$\langle G(x), x \rangle > 0 \text{ for } |x| = r_0 > 0.$$ 

Then there exists $x \in X$, with $|x| \leq r_0$ such that

$$\langle G(x), x \rangle = 0.$$

**Theorem A.2.** (Schauder’s (see p. 417 [34])) Let $X$ be a Banach space. Assume that:

(i) $A \subset X$ is closed and convex.
(ii) $T : A \to A$ is continuous.
(iii) $\overline{T(A)}$ is compact in $X$.

Then $T$ has a fixed point $x^* \in A$.

**Theorem A.3.** (Browder-Minty (see p. 557 [37])) Let $X$ be a real, separable, reflexive Banach space and let $T : X \to X^*$ (the dual of $X$) be bounded, continuous and strongly monotone. Then

$$T(u) = g$$

has a unique solution for each $g \in X^*$.
