Measurement of the CKM angle $\gamma$ using $B \to DK$ decays

1. Introduction

$CP$ violation was first established in $K_L^0 \to \pi^+ \pi^-$ decays in 1964 [1] and since then it has been observed in several $K$ and $B$ meson weak decays [2]. In the standard model of particle physics (SM) $CP$ violation in the quark sector of the weak interactions arises from a single irreducible phase in the Cabibbo-Kobayashi-Maskawa (CKM) matrix [3] that describes the mixing of the quarks. The unitarity of the CKM matrix imposes a set of relations among its elements, including the condition $V_{ud} V_{ub}^* + V_{cd} V_{cb}^* + V_{td} V_{tb}^* = 0$ that defines a unitarity triangle in the complex plane, shown in Fig. 1. Many measurements can be conveniently displayed and compared as constraints on sides and angles of this triangle. $CP$ violation is proportional to the area of the unitarity triangle and therefore it requires that all sides and angles be different from zero. The angle $\gamma \equiv \Phi_3 \equiv \arg(-V_{ud} V_{ub}^* / V_{cd} V_{cb}^*)$ is at present the most difficult to measure.

An important goal of flavor physics is to over-constrain the CKM matrix. The reason is twofold. First, it is desirable to determine its elements as precisely as possible because their values are fundamental parameters of the SM. Second, new physics (NP) effects could manifest themselves as inconsistencies between two or more measurements of the CKM parameters [4]. The angle $\gamma$ can be measured in decays mediated by tree amplitudes, such as $B \to D^0 K$: assuming that NP does not change the tree-level processes, its determination is not affected by effects beyond the SM\(^1\) and together with the measurement of $|V_{ub} / V_{cb}|$ provides a constraint that can be compared with those potentially sensitive to NP.

![Figure 1](image-url): Graphical representation of the unitarity constraint $V_{ud} V_{ub}^* + V_{cd} V_{cb}^* + V_{td} V_{tb}^* = 0$ as a triangle in the complex plane [3].

In the following we will describe and discuss the main techniques to measure the angle $\gamma$ based on the measurement of $B \to DK$ decays and we will summarize the results.

2. Measurement of $\gamma$ with flavor-tagged $B \to DK$ decays

The most powerful method used so far exploits the interference between $b \to c\bar{u}s$ and $b \to u\bar{c}s$ amplitudes in $B \to DK$ decays, whose relative weak phase is $\gamma$. In charged $B$ decays the interference is between the $B^- \to D^0 K^-$ amplitude and the color- and Cabibbo-suppressed $B^- \to \bar{D}^0 K^-$ amplitude, when $D^0$ and $\bar{D}^0$ decay to a common final state. The leading interfering diagrams are shown in Fig. 2.

\(^1\)NP may appear in $D^0 - \bar{D}^0$ mixing but the effect is expected to be small and can be taken into account [5].
Figure 2: Main Feynman diagrams contributing to the $B^- \to DK^-$ decay. The left decay proceeds through a $b \to c\bar{s}$ transition, while the right diagram proceeds via a $b \to u c\bar{s}$ transition and is both color- and Cabibbo-suppressed.

Let us introduce the decay amplitudes $A(B^- \to D^0 K^-) = A_c e^{i\delta_c}$, $A(B^- \to \bar{D}^0 K^-) = A_u e^{i(\delta_u - \gamma)}$, $A(D^0 \to f) = A_f e^{i\delta_f}$, and $A(\bar{D}^0 \to f) = A_{\bar{f}} e^{i\delta_{\bar{f}}}$, where $f$ is a generic final state of the $D$ meson. The parameters $\delta_c$, $\delta_u$, $\delta_f$ and $\delta_{\bar{f}}$ are strong phases, and $\gamma$ is the weak phase difference between $B^- \to D^0 K^-$ and $B^- \to \bar{D}^0 K^-$. $A_c$, $A_u$, $A_f$ and $A_{\bar{f}}$ are real and positive. The decay amplitude of $B^- \to [f]_D K^-$ is

$$A(B^- \to [f]_D K^-) = A_c A_f e^{i(\delta_c + \delta_f)} + A_u A_{\bar{f}} e^{i(\delta_u + \delta_{\bar{f}} - \gamma)},$$

and the rate can be written as

$$\Gamma(B^- \to [f]_D K^-) = A_c^2 A_f^2 \left( \frac{A_c^2}{A_f^2} + r_B^2 + 2r_B A_f A_{\bar{f}} \Re(e^{i(\delta_u + \delta_{\bar{f}} - \gamma)}) \right),$$

where $r_B = A_u/A_c$, $\delta_B = \delta_u - \delta_c$, and $\delta_D = \delta_f - \delta_{\bar{f}}$. The rate of the charge-conjugate mode is obtained from Eq. (2.2) by replacing $\gamma$ with $-\gamma$. Since with excellent approximation there are no other contributions besides the ones in Fig. 2, $\gamma$ and the unknown hadronic parameters $r_B$ and $\delta_B$ can be constrained in a theoretically clean way by measuring the yields of $B^+$ and $B^-$, provided that the $D$ decays are chosen appropriately. The same concept and equations apply to $B^\pm \to D^{*0} K^{\mp}$, $B^\pm \to D^{0} K^{\pm}$, and to the flavor-tagged $B^0 \to D^{*0} K^{0}$ decays with small, though important, modifications.

In the next three sections the main experimental methods explored so far are briefly discussed.

2.1 The GLW method

In the method proposed by Gronau, London and Wyler (GLW) the $D$ meson is reconstructed to $CP$ eigenstate final states $f_{CP \pm}$, such as $K^+ K^-$ ($CP = +1$) or $K^0 \pi^0$ ($CP = -1$). Therefore $A_f/A_{f_{CP \pm}} = 1$, $\delta_D = 0, \pi$ for $CP = 1, -1$, and Eq. (2.2) becomes

$$\Gamma(B^- \to [f_{CP \pm}]_D K^-) = A_c^2 A_{f_{CP \pm}}^2 \left( 1 + r_B^2 \pm 2r_B \cos(\delta_B - \gamma) \right).$$

The decay $B \to DK^*$ can also be measured as part of the Dalitz plot analysis of $B \to DK\pi$. See [8] and references therein.
Equation (2.3) and its \(CP\)-conjugate are used to define four observables which depend on the physical parameters \(\gamma\), \(\delta_B\) and \(r_B\):

\[
A_{CP\pm} = \frac{\Gamma(B^- \rightarrow D_{CP\pm}^0 K^-) - \Gamma(B^+ \rightarrow D_{CP\pm}^0 K^+)}{\Gamma(B^- \rightarrow D_{CP\pm}^0 K^-) + \Gamma(B^+ \rightarrow D_{CP\pm}^0 K^+)} = \frac{\pm 2r_B \sin \delta_B \sin \gamma}{1 + r_B^2 + 2r_B \cos \delta_B \cos \gamma},
\]

\[
R_{CP\pm} = \frac{\Gamma(B^- \rightarrow D_{CP\pm}^0 K^-) + \Gamma(B^+ \rightarrow D_{CP\pm}^0 K^+)}{2\Gamma(B^- \rightarrow D^0 K^-)} = 1 + r_B^2 \pm 2r_B \cos \delta_B \cos \gamma,
\]

where \(\Gamma(B^- \rightarrow D_{CP\pm}^0 K^-) \equiv \Gamma(B^- \rightarrow [f_{CP\pm} D K^-]/BF(D^0 \rightarrow f_{CP\pm})\) and \(\Gamma(B^- \rightarrow D^0 K^-) \equiv A^2 \equiv \Gamma(B^- \rightarrow [K^- \pi^+] D K^-)/BF(D^0 \rightarrow K^- \pi^+)\). \(A_{CP\pm}\) and \(R_{CP\pm}\) are bound by the relation \(R_{CP+} A_{CP+} + R_{CP-} A_{CP-} = 0\).

Both BaBar and Belle have reconstructed \(B^- \rightarrow D^0 K^-\) and \(B^- \rightarrow D^{*0} K^-\) decays with \(D^{*0} \rightarrow D^0 \pi^0\). BaBar has also selected the mode \(D^{*0} \rightarrow D^0 \pi^-\) and the decay \(B^- \rightarrow D^0 K^{*-}\) with \(K^{*-} \rightarrow K_S^0 \pi^-\). \(D^0\) mesons have been reconstructed in \(CP\)-even \((K^+ K^-\) and \(\pi^+\pi^-\)) and \(CP\)-odd \((K_S^0 \pi^0, K_S^0 \phi\) and \(K_S^0 \omega\)) eigenstates. Recently also CDF has measured \(B^- \rightarrow D^0 K^-\) with \(D^0 \rightarrow K^+ K^-\) and \(\pi^+\pi^-\). The data samples used by BaBar and Belle consist of 382 and 275 million \(B\bar{B}\) pairs, respectively, while CDF has used 1.0 fb\(^{-1}\) of data. The results are summarized in Table 1.

Due to the discrete 8-fold ambiguity in the extraction of \(\gamma\) from \(R_{CP\pm}\) and \(A_{CP\pm}\), and the still large uncertainty on \(r_B\), the GLW measurements have a poor constraining power on \(\gamma\) when they are considered alone. However, they generally improve the knowledge of \(r_B\), \(\gamma\) and \(\delta_B\) when combined with the results of the Dalitz method discussed in Sec. 2.3. This aspect is further discussed in Sec. 3.

### Table 1: Summary of \(R_{CP\pm}\) and \(A_{CP\pm}\) measurements.

| Mode           | Experiment | \(A_{CP+}\)       | \(A_{CP-}\)       | \(R_{CP+}\)       | \(R_{CP-}\)       |
|----------------|------------|-------------------|-------------------|-------------------|-------------------|
| \(B \rightarrow D^0 K\) | BaBar [10] | 0.27 ± 0.09 ± 0.04 | 0.09 ± 0.09 ± 0.02 | 1.06 ± 0.10 ± 0.05 | 1.03 ± 0.10 ± 0.05 |
|                | Belle [11] | 0.06 ± 0.14 ± 0.05 | 0.12 ± 0.14 ± 0.05 | 1.13 ± 0.16 ± 0.08 | 1.17 ± 0.14 ± 0.14 |

| \(B \rightarrow D^0 K^+\) | BaBar [14] | 0.09 ± 0.13 ± 0.06 | —                 | 2.17 ± 0.35 ± 0.09 | 1.03 ± 0.27 ± 0.13 |

#### 2.2 The ADS method

In the method proposed by Atwood, Dunietz and Soni (ADS) [15] the \(D\) meson is reconstructed in doubly Cabibbo-suppressed (DCS) states. We consider \(D^0 \rightarrow K^+ \pi^-\) as an example in the following discussion. The decay rate of the process \(B^- \rightarrow [K^+ \pi^-]_{D K^-}\) is the result of the interference between \(B^- \rightarrow D^0 K^-\) followed by the DCS \(D^0 \rightarrow K^+ \pi^-\), and the suppressed \(B^- \rightarrow D^0 K^-\) followed by the Cabibbo-allowed \(D^0 \rightarrow K^+ \pi^-\). From Eq. (2.2) we find

\[
\frac{\Gamma(B^+ \rightarrow [K^+ \pi^+]_{D K^+})}{\Gamma(B^- \rightarrow [K^+ \pi^-]_{D K^+})} = r_B^2 + r_D^2 + 2r_B r_D \cos(\delta_B + \delta_D),
\]

(2.6)
where both \( r_D = \frac{A_f}{A_f} = |A(D^0 \rightarrow K^+\pi^-)/A(D^0 \rightarrow K^-\pi^+)| \) and the strong phase difference \( \delta_D \) are measured independently \([3, 31]\). Defining \( R_{ADS} \) and \( A_{ADS} \) as

\[
R_{ADS} = \frac{\Gamma(B^- \rightarrow [K^+\pi^-]_D K^-) + \Gamma(B^+ \rightarrow [K^-\pi^+]_D K^+)}{\Gamma(B^- \rightarrow [K^-\pi^+]_D K^-) + \Gamma(B^+ \rightarrow [K^+\pi^-]_D K^+)}, \tag{2.7}
\]

\[
A_{ADS} = \frac{\Gamma(B^- \rightarrow [K^+\pi^-]_D K^-) - \Gamma(B^+ \rightarrow [K^-\pi^+]_D K^+)}{\Gamma(B^- \rightarrow [K^+\pi^-]_D K^-) + \Gamma(B^+ \rightarrow [K^-\pi^+]_D K^+)} \tag{2.8}
\]

it follows

\[
R_{ADS} = r_B^2 + r_D^2 + 2r_B r_D \cos \gamma \cos(\delta_B + \delta_D), \tag{2.9}
\]

\[
A_{ADS} = 2r_B r_D \sin \gamma \sin(\delta_B + \delta_D)/R_{ADS}. \tag{2.10}
\]

Since \( r_D(K\pi) = (5.78 \pm 0.08)\% \) \([17]\) and \( r_B \) is expected to be around 10\%, the interference effect can be quite large. Similar relations, with small modifications, are derived for \( B^- \rightarrow D^{*0}K^- \) and \( B^- \rightarrow D^0K^{*-} \) decays (see \([3]\) and refs. in Table 2) and for multi-body \( D^0 \) final states \([18, 19]\). Both BaBar and Belle have reconstructed the decay \( B^- \rightarrow D^0K^- \) followed by \( D^0 \rightarrow K^+\pi^- \) on datasets of 467 and 657 million \( B\bar{B} \) pairs, respectively. BaBar has also selected \( B^- \rightarrow D^{*0}K^- \) with \( D^{*0} \rightarrow D^0\pi^0 \) and \( D^0 \rightarrow D^0\gamma \) (467 \( \times 10^6 \) \( B\bar{B} \)), and \( B^- \rightarrow D^0K^{*-} \) with \( K^{*-} \rightarrow K_S^0\pi^- \) (379 \( \times 10^6 \) \( B\bar{B} \)). On a dataset of 465 million \( B\bar{B} \) pairs BaBar has performed the first measurement of flavor-tagged decays \( B^0 \rightarrow D^0K^{*0} \) with \( K^{*0} \rightarrow K^+\pi^- \), selected in the \( D^0 \) final states \( K^+\pi^- \), \( K^+\pi^-0 \) and \( K^+\pi^-\pi^-\pi^+ \). The results are summarized in Table 3. Due to the smallness of the involved branching fractions no evidence of signal has been observed so far and the null measurements have been used to set upper limits on \( r_B \). The strongest hint of signal has been reported by BaBar with a statistical significance of \( 2.6\sigma \) for \( B^+ \rightarrow D^0(K_S^0\pi^+)K^+ \). Even when a signal is observed the constraining power on \( \gamma \) of the ADS method is weak when it is used alone, but it becomes significant when the ADS information is combined with the other methods. This aspect is discussed in Sec. 3.

### 2.3 The Dalitz or GGSZ method

If \( D^0 \) decays to a 3-body final state such as \( D \rightarrow K_S^0\pi^+\pi^- \), the decay amplitudes of \( D^0 \) and \( \bar{D}^0 \) can be written as \( A_f e^{i\delta_f} = f(m_2^2, m_3^2) \) and \( A_{\bar{f}} e^{i\delta_{\bar{f}}} = f(m_2^2, m_3^2) \), where \( m_2^2 \) and \( m_3^2 \) are the squared masses of the \( K_S^0\pi^- \) and \( K_S^0\pi^+ \) combinations. The rate in Eq. 2.2 becomes

\[
\Gamma(B^+ \rightarrow [K_S^0\pi^-\pi^+]_D K^+) \propto |f(m_2^2, m_3^2)|^2 + r_B^2 |f(m_2^2, m_3^2)|^2 + 2r_B |f(m_2^2, m_3^2)||f(m_2^2, m_3^2)| \cos(\delta_B + \delta_D(m_2^2, m_3^2) + \gamma), \tag{2.11}
\]

where \( \delta_D(m_2^2, m_3^2) \) is the strong phase difference between \( f(m_2^2, m_3^2) \) and \( f(m_2^2, m_3^2) \). The amplitudes \( f(m_2^2, m_3^2) \) are measured through a Dalitz plot analysis on a large sample of flavor-tagged \( D^0 \) decays. Therefore, the \( B^+ \) yields in Eq. 2.11 only depend on the unknowns \( \gamma, \delta_B \) and \( r_B \). The great advantage of this method \([23]\) is that the relation between the signal yields and the physics parameters varies over the Dalitz plot, making possible the extraction of \( \gamma \) with only a 2-fold ambiguity (\( \gamma \rightarrow \gamma + 180^\circ \)). Furthermore, the \( D^0 \rightarrow K_S^0\pi^+\pi^- \) branching fractions is relatively large (\( \approx 3\% \)). Since the direct extraction of \( r_B, \delta_B \) and \( \gamma \) through a maximum likelihood fit (MLF) using Eq. 2.11 overestimates \( r_B \) and underestimates the statistical error of \( \gamma \) and \( \delta_B \), it is convenient to express Eq. 2.11 in terms of the cartesian coordinates \( x_\pm = \text{Re}[r_B e^{i(\delta_B \pm \gamma)}], y_\pm = \text{Im}[r_B e^{i(\delta_B \pm \gamma)}] \)

\[
\Gamma(B^+ \rightarrow D^0[\rightarrow K_S^0\pi^+\pi^-]K^+) \propto |f_+|^2 + (x_+ + y_+)^2 |f_+|^2 + 2 \left[ x_+ \text{Re}[f_+ f_\mp^*] + y_+ \text{Im}[f_+ f_\mp^*] \right] \quad (2.12)
\]
where the notation was simplified using \( f_\pm = f(m_\pi^2, m_\Xi^2) \). The extraction of \( x_\pm \) and \( y_\pm \) with a MLF using Eq. \ref{eq:MLF} is unbiased. The physics parameters \( \gamma, r_B \) and \( \delta_B \) are extracted from \( x_\pm \) and \( y_\pm \) with a frequentist statistical procedure.

BaBar has used this approach to measure the angle \( \gamma \) with \( B^- \to D^0 K^- \), \( D^{*0} K^- \) (\( D^{*0} \to D^0 \rho^0 \) and \( D^0 \gamma \)) and \( D^0 K^{*-} (K^{*-} \to K_S^0 \pi^-) \), with \( D^0 \to K_S^0 \pi^+ \pi^- \) and \( K_S^0 K^0 K^- \) using a sample of 386 million \( B \bar{B} \) pairs \cite{BaBarKPi}. Belle has selected \( B^- \to D^{(*)0} K^- \) decays (\( D^{*0} \to D^0 \rho^0 \) and \( D^0 \gamma \)) with \( D^0 \to K_S^0 \pi^+ \pi^- \) on a sample of 657 million \( B \bar{B} \) pairs \cite{BelleKPi}. The \( D^0 \to K_S^0 \pi^+ \pi^- \) and \( D^0 \to K_S^0 K^0 K^- \) decay amplitudes are determined with Dalitz plot analyses of large and very pure samples of \( D^0 \) mesons from \( D^{*+} \to D^0 \pi^+ \) decays produced in \( e^+ e^- \to c \bar{c} \) events. The amplitudes are described using an isobar model, consisting of a coherent sum of two-body amplitudes (parameterized using relativistic Breit-Wigner) plus a “nonresonant” term. BaBar has described the \( \pi \pi \) and \( K \pi \) S-wave amplitudes in \( D^0 \to K_S^0 \pi^+ \pi^- \) using a \( K \)-matrix formalism (see \cite{BaBarKPi} for a detailed discussion).

The results for \( x_\pm \) and \( y_\pm \) are reported in Table \ref{tab:results}. From the \((x_\pm, y_\pm)\) confidence regions both BaBar and Belle determine the 1\( \sigma \) confidence intervals of \( \gamma, \delta_B \) and \( r_B \) using a frequentist procedure. BaBar finds \( \gamma = (76 \pm 22 \pm 5 \pm 5)^0 \) and Belle \( \gamma = (76^{+12}_{-13} \pm 4 \pm 9)^0 \) (\( B^\pm \to D^{(*)0} K^{\pm} \)), where the solution closest to the SM average has been quoted. All results are reported in Table \ref{tab:results}.

Figure \ref{fig:contours} shows the \((x_\pm, y_\pm)\) contours for \( B \to D^0 K \) as measured by Belle (top-left) and BaBar (bottom-left), the projections of confidence regions onto the \((\gamma, r_B)\) and \((\gamma, \delta_B)\) plane obtained by Belle, and the confidence-level as a function of \( r_B \) and \( \gamma \) found by BaBar. The combined \( B \to D^{(*)0} K^{(*)} \) measurements of BaBar and Belle correspond to 3.0\( \sigma \) and 3.5\( \sigma \) evidence of \( CP \) violation, respectively.

It is interesting to ask why the statistical error measured by Belle is about twice smaller than what BaBar finds, despite the fact that the experimental observables \( x_\pm, y_\pm \) have similar uncertainties. The error on \( \gamma \) scales roughly as \( 1/r_B \). Since Belle measurements have central values of \( r_B \) between 1.5 and 3.5 times larger than BaBar values, though consistent within the errors, the result-

\[ \text{Table 2: Summary of } R_{ADS} \text{ and } A_{ADS} \text{ measurements, and limits on } r_B. \]

The uncertainty of Belle is smaller. The concept is illustrated in Fig. 4a. Fluctuations of the $\gamma$ error
due to the “1/r$B$” effect are expected to decrease as the relative uncertainty on r$B$ will become smaller.

At present the Dalitz method has the best sensitivity to $\gamma$. However, the uncertainty associated to
the Dalitz model of the D final state is already the dominant contribution to the systematic error
and it may be difficult to reduce it greatly in the future. To bypass this limit a model-independent
analysis is required [23]. At the price of a small loss of statistical power [29], the method is free of
model-dependent assumptions on the D decay and therefore it is a promising approach to follow at
LHCb and at the next generation B-factories. It requires the use of entangled $\Psi(3770) \to D\bar{D}$
decays at tau-charm factories such as CLEO-c, BES-III or next generation Super Flavor factories [5]. It has been recently shown that using 818 pb$^{-1}$ of CLEO-c data an error on $\gamma$ of $\sim 2^\circ$ associated
to the knowledge of the relative strong phase difference of $D^0 \to K^0_S \pi^+ \pi^-$ and $\bar{D}^0 \to K^0_S \pi^+ \pi^-$
can be obtained [50].

BaBar has applied the Dalitz method also to flavor-tagged $B^0 \to D^0 K^{(*)}$ decays, with $K^{(*)} \to K^+ \pi^-$ and $D^0 \to K^0_S \pi^+ \pi^-$. On a dataset of 371 million $B\bar{B}$ pairs $39 \pm 9$ signal candidates have been selected. Using the $D^0$ Dalitz plot model obtained in the charged $B$ analysis and imposing
an external measurement of $r_B$, a loose constraint on $\gamma$ was set [51]. Self tagging $B^0 \to D^0 K^{(*)}$

Table 4: Measurement of $\gamma$, $\delta_B$ and $r_B$ in $B^- \to D^{(*)}K^{(*)}$ decays reconstructed by BaBar and Belle.

| Parameter       | BaBar         | Belle          |

decays and time-dependent measurements of $B^0 \rightarrow D K^0$ decays are expected to be powerful tools to measure $\gamma$ at LHCb and at the next generation $B$-factories, where their production will be abundant and the large interference ($r_B \sim 0.4$) can be fully exploited.

**Figure 3:** Top row: Belle; bottom row: BaBar. 1σ and 2σ contours in the $(x, y)$ plane of $B^{\pm} \rightarrow D^{0} K^{\pm}$ (top-left); projections of confidence regions for the $B \rightarrow DK$ mode onto the $(r_B, \gamma)$ plane (top-center) and onto the $(\delta_B, \gamma)$ plane (top-right); 1- and 2-standard-deviation regions in the $(x, y)$ plane of $B^{\pm} \rightarrow D^{0} K^{\pm}$ (bottom-left); 1-CL as a function of $r_B$ (bottom-center) and $\gamma$ (bottom-right) for $B \rightarrow D^0 K, D^*0 K$ and $D^*0 K^*$.

### 3. Note on the cartesian coordinates

The output of the GLW and ADS methods can be expressed in terms of the same cartesian coordinates $x_{\pm} = r_B \cos(\delta_B \pm \gamma)$ and $y_{\pm} = \sin(\delta_B \pm \gamma)$ measured with the Dalitz method. This alternative way to quote the results can be useful when different methods are compared or combined. In this section we will derive the alternative parameterization and will discuss some of the advantages with respect to the classic observables.

From the definitions in Sec. 2.1 we can write $\Gamma(B^{-} \rightarrow D^{0}_{CP+} K^{-})/\Gamma(B^{-} \rightarrow D^{0} K^{-}) = 1 + x^2 + y^2 \pm 2x_-$, from which it follows

\[
\frac{1}{4} \left( \frac{\Gamma(B^{-} \rightarrow D^{0}_{CP+} K^{-})}{\Gamma(B^{-} \rightarrow D^{0} K^{-})} - \frac{\Gamma(B^{-} \rightarrow D^{0}_{CP-} K^{-})}{\Gamma(B^{-} \rightarrow D^{0} K^{-})} \right) = x_-, \tag{3.1}
\]

\[
\frac{1}{2} \left( \frac{\Gamma(B^{-} \rightarrow D^{0}_{CP+} K^{-})}{\Gamma(B^{-} \rightarrow D^{0} K^{-})} + \frac{\Gamma(B^{-} \rightarrow D^{0}_{CP-} K^{-})}{\Gamma(B^{-} \rightarrow D^{0} K^{-})} \right) - 1 = x^2 + y^2. \tag{3.2}
\]
Measurement of the CKM angle $\gamma$ using $B \rightarrow DK$ decays

Matteo Rama

Figure 4: a): Geometric definition of $\gamma$ in the $(x_{\pm}, y_{\pm})$ plane and pictorial description of how its uncertainty changes as a function of $r_B$. Circles represent $x_{\pm}, y_{\pm}$ error regions for $B^+$ (▲) and $B^-$ (▼) and the dashed lines delimit the range of variation of $2\gamma$. b,c,d): 1- and 2-standard deviation regions in the $(x_{\pm}, y_{\pm})$ plane using the GLW (b), ADS (c) and Dalitz (d) methods, on a dataset of $1ab^{-1}$. The assumptions used are discussed in the text.

The same relations hold for $x_+$ and $x^2_+ + y^2_+$ after replacing $B^-$ with $B^+$. Equation 3.1 has been used by BaBar to measure $x_+$ with the GLW analysis$^3$, whose results are reported in Table 3. It is interesting that the measurements of $x_+$ performed with the GLW and Dalitz methods have about the same uncertainty on datasets with similar size. The constraint given by Eq. 3.2 is much looser because of the quadratic dependence on $x, y$ and the fact that $r_B \ll 1$. Therefore, the GLW method measures $x_+$ quite precisely but not $y_+$, and this is the reason why it can hardly constrain $\gamma$ when it is considered alone. When combined with the Dalitz method, however, the overall error of $\gamma$ can improve significantly.

$^3$The relation was expressed in terms of $R_{CP\pm}$ and $A_{CP\pm}$. 
Proceeding in a similar way, Eq. 2.7 of the ADS method can be written as

\[
\frac{\Gamma(B^+ \rightarrow [K^\pm \pi^\mp]_{D K^\mp})}{\Gamma(B^+ \rightarrow [K^\mp \pi^\pm]_{D K^\mp})} = (x_+ + r_D \cos \delta_D)^2 + (y_+ - r_D \sin \delta_D)^2,
\]

that represents two circles in the $(x_+, y_+)$ plane centered at $(-r_D \cos \delta_D, r_D \sin \delta_D)$ and with radii $R_+ = \sqrt{\frac{\Gamma(B^+ \rightarrow [K^\pm \pi^\mp]_{D K^\mp})}{\Gamma(B^+ \rightarrow [K^\mp \pi^\pm]_{D K^\mp})}}$. It is not possible to determine $\gamma$ with only the ADS analysis of $B \rightarrow D^0 K$ because the true $x_+, y_+$ points are delocalized over two circles\(^4\). However, the measurement can be combined with the Dalitz and GLW analyses to reduce the overall error of $x_+, y_+$, and therefore the uncertainty of $\gamma$. Figure 4 shows the constraints provided by the GLW, ADS and Dalitz measurements with $B \rightarrow D^0 K$ decays on a dataset of 1ab\(^{-1}\), assuming \{$\gamma, r_B, \delta_B, r_D, \delta_D$\} = \{75\°, 0.1, 110\°, 0.06, 191\°\} in a scenario where the measured observables are centered to their true value. The uncertainty on the values of $r_D$ and $\delta_D$ was neglected when drawing the ADS constraint.

4. Conclusions

Despite the fact that BaBar and Belle have collected almost 1.5 ab\(^{-1}\) of data, a precise measurement of the CKM phase $\gamma$ is not yet available. This is not surprising if one thinks that the typical branching fractions of the involved decays are of the order of $10^{-6}$ or smaller and the interference term is found to be around 10\% in the main decay modes. In fact, the sensitivity reached by the $B$-factories is much better than it was initially foreseen. The decays $B^\pm \rightarrow D^{(*)0} K^{(*)\pm}$ are currently the most sensitive tool. The method where the $D$ meson decays to $K^0_S h^+ h^- (h = \pi, K)$ has the smallest uncertainty, ranging between 15\° and 24\° including systematics. The dominant source of systematic uncertainty currently comes from the Dalitz model of the $D$ final state.

Using a Bayesian statistical procedure and combining BaBar and Belle results of GLW, ADS and Dalitz methods, the UTfit collaboration finds $\gamma = (78 \pm 12)\°$\(^5\), while CKMfitter using a frequentist approach quotes $\gamma = (73^{+22}_{-23})\°$\(^5\). The results are reported in Fig. 3. To reduce the error to a few degrees we have to wait for LHCb ($\sigma_\gamma \approx 2 - 3\°$ with 10 fb\(^{-1}\)\(^5\)) or a Super Flavor factory ($\sigma_\gamma \approx 1\°$ with 75ab\(^{-1}\)).

\(^4\)In the case of $B \rightarrow D^{(*)0} K$ the circles associated to $D^{(*)0}$ and $D^{(*)}\gamma$ are centered at opposite points $(\pm r_D \cos \delta_D, \pm r_D \sin \delta_D)$ because of the effect pointed out in [3]; therefore the resulting constraint in the $(x_+, y_\pm)$ plane is the intersection of two circles and in principle it is possible to determine $\gamma$ up to a discrete ambiguity.

\(^5\)The average is not updated with the most recent BaBar’s $B \rightarrow D^{(*)0} K^{(*)}$ ADS and Belle’s Dalitz measurements.
