Abstract. Under the conditions of the south-western part of the Central Black-soil region in the grain-and-plant crop rotation on the black-soil the typical maximum yield of winter wheat was 5.52 t/ha when using the organic-mineral fertilizer system as part of mineral fertilizers in the dose of N60P60K60 and manure in the dose of 40 t/ha according to the third level of plant protection (seed etching of herbicide fungicide insecticide growth substances) with maximum payback of 1 kg of mineral fertilizers with grain harvest increase – 15.5 kg. Yield increase at the 1st level of plant protection (seed etching) was 1.86 t/ha (68.1%), at the 2nd level of protection (seed etching of herbicide fungicide) – 2.55 t/ha (93.4%) and at the 3rd level of protection – 2.79 t/ha (102.2%). The highest increase from pesticides was 0.69 and 0.93 t/ha (15.0 and 20.3%), respectively. The use of such a fertilizer system is justified, in which the energy coefficient was 1.03 and 1.05. The design of an organic fertilizer system using manure does not meet the requirements of bioenergy efficiency at all levels of plant protection (Kee = 0.79-0.87).

1 Introduction

Relevance. At present, with the growing economic and environmental problems of the modern state of agriculture of our country, there is a need for large-scale improvement of winter wheat cultivation technologies, as its potential is not fully realized [1, 2, 10, 14]. In this regard, the production of high grain yields is mainly ensured by an optimal combination of plant protection agents [13, 8, 3], the use of mineral [7, 11, 15] and organic fertilizers [9], as well as the use of an organic-mineral fertilizer system [5, 6]. Agricultural enterprises are offered biological and biological technologies using all types of organic fertilizers in combination with a system of protection of culture [12, 5, 4]. However, data from previous studies need to be refined in a given soil-climate zone.

The research aimed at agroecological justification of winter wheat cultivation technologies based on a combination of fertilizer systems and plant protection levels in the south-western part of the CBR.

The research has addressed the following challenges:
1. To study the regularity of the effect of fertilization systems on the dynamics of the content of movable forms of food elements in black-soil typical;
2. Determine the effect of fertilizer systems on the clogging of winter wheat crops depending on plant protection levels;
3. To establish the nature of the influence of the complex of agricultural techniques on the yield and quality of winter wheat grain;
4. Carry out an analysis of the bioenergy efficiency of fertilizers depending on the levels of plant protection.

The scientific novelty is that for the first time in the Central Black-soil region, a comprehensive assessment of the different intensity of winter wheat cultivation technologies based on a combination of fertilization and plant protection systems has been carried out in a long-term stationary experience. The influence of various technologies of winter wheat cultivation on nutritional regime, crop clogging, grain yield and quality, crop structure is shown.

The practical significance of the work is that the results of the carried out studies can be used in the development of technologies for the cultivation of winter wheat, in which, on the basis of a combination of the most important agricultural techniques - fertilization and plant protection systems - are combined into a single whole principles of increasing the productivity of rations, environmental protection and resource saving.

Growing winter wheat according to these technologies allows, on the basis of constant monitoring of the content of food elements in the soil and control of energy consumption per unit of production, to increase soil fertility, increase the yield of winter wheat grain and increase its quality.

2 Meteorological conditions of the study period

According to the amount of atmospheric precipitation, the territory of the experimental field of FSBSU "Belgorod FASC RAS", where the research was carried out, belongs to the zone of moderate moisturization. The average annual rainfall recorded by the Race weather station was 553 mm as of 2019. On average, precipitation fell by 57.2 mm or 10.3% of the average summer values in two agricultural years.

The largest number fell in 2017/2018 agricultural year: the excess was 301.8 mm or 54.6% of the average multi-year values, and during the spring-summer vegetation period - April-July - 166.2 mm or 75.5%. The most rainy was July, when 3.6 monthly rates (247.4 mm) fell.

In the 2018/2019 agricultural year, there was a precipitation deficit of 147.4 mm or 27.7%. In the period April-July the deficit was less - 40.7 mm or 18.5%. The most arid was June, when 12.5 mm of precipitation or 19.8% of the norm fell.

The average daily air temperature during the study years exceeded the average multi-year values by 3.6° C. The excess in the 2017/2018 agricultural year was 3.5° C, and in the 2018/2019 agricultural year 3.8° C. At April-July average multi-year values of 15.0° C, the air temperature was higher by 3.8 and 3.7° C, respectively. The largest increase was in May 2018 (5.8° C) and June 2019 (6.6° C).

The hydrothermal coefficient (HTC according to Selyaninov) was 1.69 and 0.79 respectively over the years, with an average of 1.03.
3 Methodology of research

Comprehensive studies on the studied topic were carried out on the experimental field of FSBSU "Belgorodsky FASC RAS" in a long-term field stationary experience in grain-based 5-Polish crop rotation with such rotation: black steam, winter wheat, sugar beet, barley, corn per grain.

The soil of the test site is the black-soil of a typical heavy carbon granulometric composition with humus content of 4.5-5.0%, sum of absorbed bases 37-40 mg-eq./100 g of soil, hydrolytic acidity of soil 1.6-1.8 mg-eq./100 g of soil, pH$_{KCl}$ 5.8-5.9 and content of movable phosphorus and exchange potassium (according to Chirikov), respectively, 55-60 and 105-125 mg/kg of soil.

The experience is laid down in 3-fold repetition by the method of split divisions. The effect and interaction of various combinations of two factors of technological techniques, including the 4 fertilizer system and the 3 plant protection system were studied. Ploughing to a depth of 20-22 cm was used as the main soil treatment method.

Experience diagram with fertilizers:
1) control (without fertilizers);
2) N$_{60}$P$_{60}$K$_{60}$;
3) manure 40 t/ha - background;
4) background + N$_{60}$P$_{60}$K$_{60}$.

The plant protection system had 3 levels:
1) seed etching (Dospeh 3, KS - 0.50 l/t Tabu, FRS - 0.50 l/t seeds);
2) the same as 1 herbicides (in the cutting phase) Asterix, SE - 0.60 l/ha fungicide (in the piping phase) Alcor Super, CE - 0.50 l/ha.
3) same as 2 Clonrin insecticide, CE - 0.20 l/ha Nowil, RE - 0.03 l/ha.

Mineral fertilizers (an azofoska 16:16:16) brought on allotments manually, the semi-errerotting manure of cattle - a navozorazbrasyvatel, means of protection of plants - the OP-2000 sprayer.

The winter wheat variety Synthetic, zoned in the region, was sown.

The methodological basis of the studies carried out was a field experiment. The research was guided by generally accepted methods, according to which the following observations and calculations were carried out:

- Agrometeorological indicators were recorded on the weather bridge located on the territory of the experimental field of FSBSU "Belgorod FASC RAS" in accordance with the "Manual for agrometeorological posts";
- during vegetation of a winter wheat determined content in the soil of nitrate nitrogen (Russian Standard 26488-85), mobile phosphorus and exchange potassium on Chirikova (Russian Standard 26204-91), soil samples selected during shoots and during harvesting of a winter wheat in layers of earth 0-10, 10-20, 20-30 cm;
- Taking into account the clogging of winter wheat crops was carried out in two terms by quantitative-weight method according to the method of VISR (1990). The first count is before treatment with herbicide, the second count is 30 days after treatment;
- In the phase of complete ripeness of winter wheat, snoop samples were taken to determine the structure of the crop (height of plants, total number of stems, number of productive stems, weight of grain from one colos);
- The harvest was carried out with the help of Sampo-500 combine by method of continuous harvesting of the recorded area of the lessons of experience;
- The resulting yield was calculated by 100% purity and 14% humidity.

From each repetition of the test, grain samples were taken to determine humidity (Russian Standard 13586.5), percentage of weed impurity (Russian Standard 30483-97),
mass of 1000 grains (Russian Standard 10842-89), nature of grain (Russian Standard 10840-64);
- Statistical processing of the obtained data was carried out by dispersion analysis using computer programs (NIRSM MAIN, Microsoft Office Excel 2010).

4 Discussion of the received results. Impact of fertilizers and plant protection on the content of. In soil of movable forms of food elements

Analysis of nitrate content during seeding showed that the most significant increase in soil layers 0-10 and 10-20 cm was observed when mineral fertilizers were applied under winter wheat in the dose of N60P60K60, as well as the combination of N60P60K60 with manure in the dose of 40 t/ha (table 1).

Table 1. Effect of fertilizers on nitrate nitrogen, mobile phosphorus and exchange potassium content in soil under winter wheat, mg/kg soil (average for plant protection levels, 2018-2019).

| Fertilizer element | Layers Soils, Cm | Without Fertilizers | N60P60K60 | Manure 40 t/ha - background | Background + N60P60K60 |

|                    | 10-20            | 51.2                | 106.0     | 57.0                        | 106.3                   |
|                    | 20-30            | 44.7                | 95.0      | 52.7                        | 96.3                    |
|                    | 0-30             | 50.9                | 105.2     | 57.3                        | 106.8                   |
| LED05              |                  |                     |           |                             |                         |
In the layer 20-30 cm variation of nitrate content depending on fertilizers is less significant. Only 40 t/ha of manure resulted in the lowest increase in manure content.

By the harvest period there was a decrease in nitrate content in the soil, and the most noticeable - in the layer 0-10 cm when growing winter wheat with mineral fertilizers (- 6.85 mg/kg of soil) and their combination with manure (- 6.61 mg/kg).

Patterns of the effect of fertilizers on the content of this food element in the soil, noted for the period of seedlings, were also evident during the harvest period. A characteristic feature for both terms of determination is a marked decrease in content with depth of the soil horizon.

The maximum nitrate content noted in the studies - 12.68 mg/kg - is well below the level MPC in soil by NO$_3$ - 130 mg/kg (Hygienic Standards GN 2.1.7.2041-06, No. CAS 14797-55-8) and cannot pose a danger to plants, animals and humans.

Changes in mobile phosphate content in soil are more significant than variations in nitrate content. Thus, the increase in phosphate content when using mineral fertilizers in the dose of N$_{60}$P$_{60}$K$_{60}$ and the combination of N$_{60}$P$_{60}$K$_{60}$ with manure in the dose of 40 t/ha was 0-10 cm in the soil layer for the period of winter wheat seeding 61.0 and 61.6 mg/kg (97.3-98.2%), respectively, and nitrate content 2.40 and 3.43 mg/kg (26.0 and 37.1%).

The decrease in phosphate content in this soil layer in absolute values (- 9.0 and - 6.6 mg/kg) is equivalent to the decrease in nitrate content (- 6.85 and - 6.61 mg/kg), but in relative values is less significant (7.3% and 5.3%) than the decrease in nitrate content (58.8 and 52.1%).

The use of 40 t/ha of manure alone contributed to the lowest increase in phosphate content in the soil.

The patterns associated with changes in the content of metabolic potassium influenced by fertilizers are similar to those noted for phosphates and to a lesser extent for nitrates. The maximum increase in its content was marked by the use of the organic-mineral fertilizer system when it amounted to 30.0 mg/kg (27.7%) in the upper 0-10 cm soil layer for the period of culture seeding.

In the mineral system growth is slightly lower - 18.0 mg/kg (16.6%), and the smallest - in the organic system - 4.4 mg/kg (4.1%), which is unreliable (LED$_{05}$ = 10.4 mg/kg).

The intensity of the decrease in the content of exchange potassium during the "seedling - harvesting" period is even lower than that of phosphates and it was observed only in soil without fertilizers - by 6.0 mg/kg (16.7%) and in the case of manure - by 6.7 mg/kg (14.9%). Moreover, these changes are unreliable, which indicate a tendency to decrease potassium content during the period of active plant vegetation.

5 Impact of fertilizers and plant protection on clogging of winter wheat crops

Analysis of the clogging of winter wheat crops revealed that seed etching before sowing (Dospeh 3, KS - 0.50 l/t Tabu, FRS - 0.50 l/t seeds) caused a decrease in clogging within 4.2-16.3% during the period of active spring-summer vegetation (Table 2).

At the same time, the more intense decline in the number of segetal vegetation was provided by fertilizers used to improve the growth and development of culture.
Application of mineral fertilizers in the dose of $N_{60}P_{60}K_{60}$ contributed to maximum reduction of clogging - by 16.3%, their combination with 40 t/ha manure - by 10.0%, application of only 40 t/ha manure - by 7.4%, while in crops without fertilizers it decreased by only 4.2%.

Obviously, seed etching in combination with fertilizers formed high immune properties of winter wheat, and more developed plants showed increased competition against weeds. Fertilizers in mineral, organic and organo-mineral systems provided increase of herbicide application efficiency from 83.9-85.7% at cultivation of winter wheat without fertilizers up to 88.5-92.6% at their use.

Studies have also found that herbicides in combination with fungicides (level 2 protection), as well as insecticides and growth substances (level 3 protection), which were previously used for other crops in crop rotation, formed agrocenosis with significantly fewer segetal plants, as evidenced by their number before herbicide treatment.

The reduction of clogging relative to the variant where only seed etching was carried out was 35.4 and 41.7% in winter wheat crops without fertilizers, respectively, 39.5 and 44.2% in fertilizer mineral system, 29.6 and 33.3% in fertilizer organic system and 34.0 and 46.0% in organic mineral system.

Table 2. Impact of fertilizers and plant protection on the clogging of winter wheat crops (2018-2019).

| Experience options | Quantity of weeds, piece/sq.m | Decrease in contamination |
|--------------------|-------------------------------|---------------------------|
|                    | Before processing | After 30 days | Piece/sq.m | %        |
| without fertilizers| 1\*                      | 48            | 46         | 2        | 4.2     |
|                    | 2                        | 31            | 5          | 26       | 83.9    |
|                    | 3                        | 28            | 4          | 24       | 85.7    |
| $N_{60}P_{60}K_{60}$| 1                        | 43            | 36         | 7        | 16.3    |
|                    | 2                        | 26            | 3          | 23       | 88.5    |

6 Impact of fertilizers and plant protection on winter wheat grain yield

The effectiveness of fertilizers and pesticides on winter wheat was dependent on different weather conditions.
In 2018, grain yields were higher (table 3) than in 2019 (table 4), but increases from mineral fertilizers are lower and from pesticides are higher.

The efficiency of manure in more arid - 2019 - is markedly less. This is due to higher moisture availability in the 2017/2018 agricultural year than in the compared one with roughly the same heat availability.

The payback of mineral fertilizers additional products, therefore, above only in the mineral system of fertilizer in 2019 which made 9.9 kg/kg and was 1.2 kg/kg higher or for 12.1% in comparison with 2018.

Table 3. Impact of fertilizers and plant protection products on winter wheat yield in 2018.

* Note. Plant protection levels: 1 - seed etching; 2 - is the same as 1 + herbicide + fungicides; 3 - same as 2 + insecticides + growth substances.

With the combination of fertilizers with pesticides, due to the different direction of effects from their use depending on weather conditions, the payback of mineral fertilizers changed little.

On average, in 2018-2019, the maximum yield of winter wheat was 5.52 t/ha according to the third level of plant protection, in which the whole complex of chemical agents was used: mineral fertilizers, manure, seed etching, herbicides, fungicides, insecticides, growth substances (table 5). The payback of 1 kg of mineral fertilizers by increasing the harvest here was the largest - 15.5 kg.

The productivity increase from joint effect of mineral fertilizers in a dose of N₆₀P₆₀K₆₀ and manure in a dose of 40 t/ha at the 1st level of protection of plants (a treatment of seeds) made 1.86 t/ha (68.1%), at the 2nd level of protection (a treatment a seed herbicides fungicides) - 2.55 t/ha (93.4%) and at the 3rd level of protection (a treatment a seed herbicides fungicides insecticides growth substances) - 2.79 t/ha (102.2%).
A slightly smaller increase in the yield of winter wheat grain was observed at a dose of $N_{60}P_{60}K_{60}$ - 1.68 t/ha (64.5%) at the 1st level of protection, with 2 and 3 levels of increase being 2.28 and 2.47 t/ha (83.5 and 90.5%), respectively.

At the same time the payback of mineral fertilizers considerably increased from the 1st level to the 2nd and 3rd respectively from 9.3 to 12.6 and 13.7 kg/kg (35.5 and 47.3%). The lowest yield increase was provided by manure at a dose of 40 t/ha - 1.09 t/ha (39.9%) at the 1st level of plant protection. At the 2nd and 3rd levels, it increased by 1.53 and 1.74 t/ha (56.0 and 63.7%), respectively.

Table 4. Impact of fertilizers and plant protection products on winter wheat yield in 2019.

|                     | 3                  | 5.11                        | 2.38                        |
| LED05              | 0.24               | -                           | -                           |

* Note. Plant protection levels: 1 - seed etching; 2 - is the same as 1 + herbicide + fungicides; 3 - same as 2 + insecticides + growth substances.

The highest increase from pesticides at the 2nd and 3rd levels of protection in the organic-mineral fertilizer system, respectively, was 0.69 and 0.93 t/ha (15.0 and 20.3%). The mineral fertilizer system contributed to an increase in grain yields from the 2nd and 3rd level of protection with the use of pesticides by 0.60 and 0.79 t/ha (13.6 and 17.9%), respectively, and organic by 0.44 and 0.65 t/ha (11.5 and 17.0%).

Organic-mineral fertilizer system to a greater extent than other systems provided a tendency to increase grain nature (13-16 g/l). Mineral system showed almost the same result (12-15 g/l), and organic - slightly less (10-14 g/l). The dependence of nature on plant protection systems is less pronounced (table 6).

Fertilizer systems have contributed to a reliable increase in the gluten content of winter wheat grains. In terms of increasing content of its fertilizer system, the following descending series is located: organo-mineral (3.8-5.3%), mineral (2.6-3.3%) and organic (2.1-2.5%).

A significant increase depending on plant protection systems (1.5%) was observed in the transition from the 1st level of protection to the 3rd level, that is, the whole complex of...
pesticides used during the spring-summer vegetation of winter wheat was added to seed etching: herbicides, fungicides, insecticides, growth substances.

7 Impact of fertilizers and plant protection for winter wheat grain quality

The most significant increase in raw protein content in grain is due to the use of mineral fertilizer system (2.0%). The organo-mineral system contributed to its growth by 1.4%.

Table 5. Impact of fertilizers and plant protection on the yield of winter wheat, average for 2018-2019.

|                    | 2                 | 5.28 | 2.31 | 77.8 | 2.55 | 93.4 | 0.69 | 15.0 | 14.2 |
|                    | 3                 | 5.52 | 2.43 | 78.6 | 2.79 | 102.2 | 0.93 | 20.3 | 15.5 |
| LED\(_{05}\) | 0.30 | - | - | - | - | - | - |

* Note. Plant protection levels: 1 - seed etching; 2 - is the same as 1 + herbicide + fungicides; 3 - same as 2 + insecticides + growth substances.

The effect of the organic system on the change in crude protein content was not evident.

Protein collection, as an integral indicator of yield and quality of production, proved to be almost equal in the application of mineral fertilizer system - \(N_{60}P_{60}K_{60}\) - 643 kg/ha and organic-mineral system - \(N_{60}P_{60}K_{60}\) in combination with 40 t/ha manure - 646 kg/ha. Growth was 315 and 318 kg/ha (96.0 and 97.0%), respectively.

Manure increased protein collection by 132 kg/ha (40.2%).

8 Impact of fertilizers and plant protection on winter wheat crop structure

Observations have shown that fertilizers have contributed to a significant increase in the number of productive winter wheat stems (table 7). The largest amount of them was in the application of organic-mineral fertilizer system with the 3rd level of protection - 462 piece/sq.m.
With the step-by-step increase in the intensity of protective measures (1, 2, 3 - plant protection levels) in crops without fertilizers, the number of productive stems increased significantly from 331 to 349 and 360 piece/sq.m. A similar pattern was observed as a result of manure application, but at a higher level - from 381 to 398 and 414 piece/sq.m. In mineral and organo-mineral fertiliser systems there is a tendency to increase them at transition from the 1st to the 2nd level of protection. And in the organ-mineral system, in addition, during the transition from the 2nd to the 3rd level of protection there is a significant increase in them.

**Table 6.** Impact of fertilizers and plant protection products on winter wheat grain quality (2018-2019).

* Note. Plant protection levels: 1 - seed etching; 2 - is the same as 1 + herbicide + fungicides; 3 - same as 2 + insecticides + growth substances.

The height of winter wheat plants increased significantly with the application of mineral fertilizers and their combinations with manure. Manure has led to a tendency to increase it. There is also a tendency to increase when herbicides and fungicides are used in the protection system.

A significant increase in the mass of 1000 grains (LED<sub>05</sub> = 1.2 g) caused mineral fertilizers in the dose of N<sub>60</sub>P<sub>60</sub>K<sub>60</sub> using the 3rd level of plant protection (1.29 g), but against it the increase in their mass under the influence of fertilizers (0.71 g) is estimated as a trend. The combined application of mineral fertilizers and manure at a dose of 40 t/ha contributed to a significant increase in the weight of zeroes at the 2nd and 3rd levels of protection (1.44 and 1.48 g, respectively). It has also been found that with each new level of protection in all fertilizer systems there has been a systematic tendency to increase the mass of 1000 grains.
The weight of grains from one wheel increased significantly when fertilizers were applied in mineral, organic and organo-mineral fertiliser systems. It was greatest at the 2nd and 3rd levels of protection using mineral and organo-mineral fertiliser systems - 1.11-1.13 g. At the same time, its increase with increasing intensity of protection means application from the 1st to the 2nd level is characterized as significant, and from the 2nd to the 3rd as a weak trend.

**Table 7.** Impact of fertilizers and plant protection on winter wheat crop structure (2018-2019).

| Experience options | Number Productive stalks, Piece/sq.m | Height Plants, Cm | Weight Is 1000 grains, G | Weight Grains From one Ear, G |

**Note.** Plant protection levels: 1 - seed etching; 2 - is the same as 1 + herbicide + fungicides; 3 - same as 2 + insecticides + growth substances.

**9 Bioenergetic efficiency of fertilizer application**

Bioenergetic efficiency analysis showed that at all levels of protection the use of mineral fertilizers in the dose of N60P60K60 is energetically justified, as the energy included in the crop increase exceeds the energy costs from the use of fertilizers, and the energy coefficient (coefficient energy efficiency, Cₑₑ) exceeds 1.0 (table 8). Accordingly, 1, 2 and 3 levels of protection were 1.80, 1.81 and 1.77, and energy costs per unit grain yield increase were 9161, 8149 and 7931 MJ/t.
Also effective at the 2nd and 3rd levels of plant protection is application of organic-mineral fertiliser system (N\textsubscript{60}P\textsubscript{60}K\textsubscript{60} + manure 40 t/ha), where energy coefficient was equal to 1.03 and 1.05. At the 1st level of protection, it is not effective in terms of bioenergetic analysis because the $C_{ee} < 1$ is 0.92.

Application of only manure without herbicides and fungicides does not justify itself, because energy costs from the use of fertilizers are paid for by the energy contained in the crop increase of only 79% ($C_{ee} = 0.79$).

When herbicides and fungicides were used, the energy associated with manure application was not covered by bioenergy in crop gain ($C_{ee} = 0.85$) at 16295 MJ/t grain yield gain energy.

The involvement of herbicides, fungicides, insecticides and growth substances in the plant protection system has also prevented a bioenergetically sound crop increase when $C_{ee} = 0.87$.

Therefore, when designing the fertilization system for the planned crop increase, it is necessary to take into account the value of energy consumption on it, which does not exceed 14437 MJ/t of increase, as if it is exceeded, bioenergetic expediency will not be observed ($C_{ee} < 1$).

Table 8. Bioenergetic efficiency of fertilizer application depending on winter wheat plant protection (2018-2019).

| Experience options                  | Protaction levels | Grain yield increases from fertilizers, T/ha | Energy in increases from fertilizer use, MJ/ha | Energy consumption from fertilizer application, MJ/ha | Power Coefficient, Piece | Energy consumption, MJ/t grain increase |
|-------------------------------------|-------------------|---------------------------------------------|-----------------------------------------------|------------------------------------------------------|--------------------------|----------------------------------------|
| **Without fertilizers**             |                   |                                             |                                               |                                                      |                          |                                        |

10 Conclusion

Studies carried out in long-term field stationary experience have shown that the nutritional regime of blackness typical during vegetation of crops, clogging of crops, productivity of winter wheat, crop structure involved in the experiment, economic and bioenergy indicators are influenced by fertilizers and plant protection means, the statistical reliability of which is determined by the peculiarities of resources, their importance for the studied objects and variability in time and space.

11 Summary

1. The greatest increase in nitrate content in the soil layer of 0-10 cm during sprouting was due to the use of a combination of mineral fertilizers in the dose of N$_{60}$P$_{60}$K$_{60}$ and manure in the dose of 40 t/ha (37.1%) under winter wheat, slightly less - the application of mineral fertilizers in the dose of N$_{60}$P$_{60}$K$_{60}$ (25.9%) and the least - the use of manure only in the dose of 40 t/ha (4.3%). For mobile phosphates, these parameters were 98.2, 97.3 and 3.2%, respectively, and for exchange potassium, 27.7, 16.6 and 4.1%. The maximum nitrate content noted in the studies - 12.68 mg/kg soil - was significantly lower than the level of MPC in the soil by NO$_3$ - 130 mg/kg (Hygienic Standards GN 2.1.7.2041-06, No. CAS 14797-55-8) and cannot pose a danger to plants, animals and humans.

2. Mineral fertilizers in the dose of N$_{60}$P$_{60}$K$_{60}$ contributed to the reduction of clogging of winter wheat crops by 16.3%, their combination with 40 t/ha manure - by 10.0%, application of only 40 t/ha manure - by 7.4%, and in crops without fertilizers it decreased by 4.2%. Herbicide efficacy increased from 83.9-85.7% in fertilizer-free crops to 88.5-92.6% in different fertilizer systems. The follow-up of herbicidal treatments carried out earlier in crop rotation was 29.6-46.0%.

3. The maximum yield of winter wheat was 5.52 t/ha using the organic-mineral fertilizer system according to the third level of plant protection, in which the whole complex of chemical agents was used: mineral fertilizers, manure, seed etching, herbicides, fungicides, insecticides, growth substances with the highest payback of 1 kg of mineral fertilizers with a crop increase of 15.5 kg. The productivity increase from joint effect of mineral fertilizers in a dose of N$_{60}$P$_{60}$K$_{60}$ and manure in a dose of 40 t/ha at the 1st level of protection of plants (a treatment a seed) made 1.86 t/ha (68.1%), at the 2nd level of protection (a treatment a seed herbicides fungicides) - 2.55 t/ha (93.4%) and at the 3rd level of protection (a treatment of seeds herbicides fungicides insecticides growth substances) - 2.79 t/ha (102.2%). The highest increase from pesticides at the 2nd and 3rd levels of protection in the organic-mineral fertilizer system, respectively, was 0.69 and 0.93 t/ha (15.0 and 20.3%).

4. Organic-mineral fertilizer system to a greater extent than other systems provided a tendency to increase grain nature (13-16 g/l).

5. According to the increase of gluten content in the grain of the fertilizer system, the following descending row is located: organic-mineral (3.8-5.3%), mineral (2.6-3.3%) and organic (2.1-2.5%).

6. The most significant increase in raw protein content in grain is due to the use of mineral fertilizer system (2.0%).

7. The largest number of productive stems of winter wheat was observed in the application of organic-mineral fertilizer system with the 3rd level of protection - 462 piece/sq.m.
8. The height of winter wheat plants increased significantly with the application of mineral fertilizers and their combinations with manure.

9. A significant increase in the mass of 1000 grains \( \text{LED}_{05} = 1.20 \) g caused mineral fertilizers in the dose of \( \text{N}_60\text{P}_60\text{K}_60 \) using the 3rd level of plant protection \( 1.29 \) g. The combined application of mineral fertilizers and manure at a dose of 40 t/ha contributed to a significant increase in the weight of zeroes at the 2nd and 3rd levels of protection \( 1.44 \) and \( 1.48 \) g, respectively.

10. The largest mass of zeroes from one wheel was at the 2nd and 3rd levels of protection using mineral and organo-mineral fertilizer systems - 1.11-1.13 g. At the same time, its increase with increasing intensity of protection means application from the 1st to the 2nd level is characterized as significant, and from the 2nd to the 3rd as a weak trend.

11. The use of mineral fertilizers in the dose of \( \text{N}_60\text{P}_60\text{K}_60 \) is bioenergetically justified, as the energy involved in the crop increase exceeds the energy costs from the use of fertilizers, and the energy coefficient (coefficient energy efficiency, \( C_{ee} \)) exceeded 1.0 and amounted to 1.80, 1.81 and 1.77, respectively, 1, 2 and 3 levels of protection at energy consumption per unit of grain yield increase 9161, 8149 and 7931 MJ/t.

At the 2nd and 3rd levels of plant protection, the use of an organic mineral fertilizer system \( \text{N}_60\text{P}_60\text{K}_60 \) manure of 40 t/ha) is justified, where the energy coefficient was 1.03 and 1.05. Even the use of herbicides, fungicides, insecticides and growth substances in the plant protection system did not produce a bioenergetically sound crop increase from manure when \( C_{ee} = 0.87 \). When designing a fertilizer system for the planned crop increase, it is necessary to take into account the energy consumption not exceeding 14437 MJ/t of the increase, as if it is exceeded, bioenergetic expediency will not be observed \( (C_{ee} < 1) \).

12. The research carried out make it possible to make following offers to production

1. In the south-west of the CBR, under conditions of unstable moisturization on black-soil typical for the purpose of preservation and increase of soil fertility and obtaining high yields of winter wheat with good quality indicators, it is necessary to design an organic-mineral fertilizer system in cultivation technology, including mineral fertilizers at a dose of \( \text{N}_60\text{P}_60\text{K}_60 \) and manure at a dose of 40 t/ha.

2. The fertilizer system for the planned crop increase should be oriented to a value of energy consumption not exceeding 14437 MJ per 1 t of the increase due to bioenergy feasibility.

3. The design of an organic fertilizer system using manure only does not seem appropriate because it does not meet the requirements of bioenergy efficiency at all levels of plant protection \( (C_{ee} = 0.79-0.87) \).

4. The norm of winter wheat seeds sowing is established on the basis of the calculation of production stems number 440-460 piece/sq.m. by the harvest period, which ensure optimal conditions of productivity formation in agroecosin.
