ABSTRACT We present an adaptive quantized state feedback tracking methodology for a class of uncertain multiple-input multiple-output (MIMO) nonlinear block-triangular pure-feedback systems with state quantizers. Uniform quantizers are considered to quantize all measurable state variables for feedback. Compared with the existing tracking approaches of MIMO lower-triangular nonlinear systems, the main contributions of the proposed strategy are developing (1) a quantized-state-feedback-based adaptive tracker in the presence of nonaffine interaction of states and control variables of MIMO systems and (2) an analysis strategy for quantized feedback stability using adaptive compensation terms to derive bounded quantization errors. In addition, the stability of the closed-loop system with quantized state feedback is analyzed based on the Lyapunov stability theorem. Finally, simulation examples, including interconnected inverted pendulums, are presented to validate the effectiveness of the proposed control strategy.

INDEX TERMS Quantized state feedback control, neural networks, state quantization, MIMO nonlinear systems, pure-feedback form.

I. INTRODUCTION
In the field of nonlinear control, adaptive recursive control techniques based on backstepping [1], dynamic surface design [2], and command-filtered backstepping design [3], [4] have been regarded as powerful tools for dealing with unmatched and uncertain nonlinearities. Adaptive control and filter designs using neural-network function approximators have been actively studied for systems with unknown nonlinearities (see [5]–[8] and references therein). To deal with more complex nonlinear systems, these techniques have been extended to multiple-input multiple-output (MIMO) nonlinear systems that include nonlinearities with couplings among system states and inputs. In [9], an adaptive fuzzy output feedback controller was designed for MIMO strict-feedback systems with unknown dead-zone inputs. In [10], an adaptive fuzzy tracking approach for MIMO nonlinear switched strict-feedback systems was studied. Adaptive neural control problems of MIMO pure-feedback nonlinear systems were addressed in [11] and [12]. In [13] and [14], fuzzy adaptive control approaches were developed for uncertain nonlinear multivariable systems. Moreover, the problems of output constraints [15] and event-triggered control [16] have been addressed for adaptive neural control designs of MIMO nonlinear systems. Contrary to these control designs using continuous feedback, industrial control systems based on digital networks require the transmission of quantized signals with finite values owing to band-limited communication channels [17]. Linear systems [18]–[20] and nonlinear control systems [21], [22] have been considered for quantized control. Several adaptive recursive control strategies have been investigated for uncertain lower-triangular single-input single-output nonlinear systems with quantized input signals [23]–[28]. Furthermore, these quantized control approaches have been adopted to address several control problems of input-quantized MIMO nonlinear systems. In [29], a tracking control problem using an observer was investigated for MIMO time-delay nonlinear systems in pure-feedback form. In [30], a prescribed performance control was proposed for interconnected MIMO nonlinear systems.
An adaptive neural control problem of switched MIMO nonlinear systems with quantized dead-zone input was addressed in [31]. In [32], an adaptive input-quantized control approach was proposed for MIMO nonlinear systems with underactuated faults and time-varying output constraints. However, these successful quantized control approaches [23]–[32] are only feasible in the presence of input quantization. In network-based control systems, the quantization of measured state variables must be considered for feedback control design because the controller and MIMO systems are connected by band-limited network channels. To the best of our knowledge, quantized state feedback control design of uncertain MIMO pure-feedback nonlinear systems has not been investigated yet.

On the other hand, quantized-state-feedback-based recursive control design problems in the presence of state quantizers have been recently addressed for nonlinear systems with parametric uncertainties [33], [34]. Neural-network-based quantized feedback control designs were developed for strict-feedback nonlinear systems with time delays [35]. Furthermore, a distributed control strategy was presented for multi-agent nonlinear systems in strict-feedback form [36]. However, these approaches fail to provide a quantized state feedback control solution for MIMO nonlinear systems with coupling of state and control variables in pure-feedback form.

A primary difficulty in addressing this problem is to deal with unknown control coefficient matrices resulting from unknown nonaffine nonlinearities via quantized feedback information of states of all subsystems coupled in nonaffine nonlinear form. Owing to unknown control coefficient matrices induced from unknown nonaffine nonlinearities, the quantized-state-based neural network adaptive control strategies reported in [35], [36] cannot be applied to ensure boundedness of close-loop quantization errors for the stability analysis of the closed-loop system. Therefore, it is important to establish quantized-state-based adaptive compensation strategies for tuning neural network approximators to guarantee that close-loop quantization errors are bounded in the presence of unknown control coefficient matrices.

To address this difficulty, we propose an adaptive quantized state feedback control methodology for uncertain MIMO nonlinear pure-feedback systems with state quantizers and external disturbances. All measurable state variables for feedback are quantized via state quantizers. An adaptive tracking scheme using quantized states is constructed in the presence of nonaffine nonlinear vectors and unknown bounds of gain matrices derived using the mean value theorem. In the proposed scheme, adaptive neural compensation terms using quantized state feedback are introduced to analyze quantization errors between unquantized and quantized signals in a closed-loop system. In addition, we analyze the boundedness of estimated parameters and quantization errors by establishing technical lemmas. Finally, the stability of the proposed control system is proved using the Lyapunov stability theorem. The main contributions of this study are as follows:

(i) Contrary to previous results [23]–[32] in which the input quantization problems were only considered in quantized control for MIMO lower-triangular nonlinear systems, this study addresses the state quantization problem for uncertain MIMO nonlinear pure-feedback systems. A neural-network-based quantized state feedback control strategy is developed to ensure the boundedness of quantization errors in the presence of unknown pure-feedback nonlinearities. In addition, adaptive function approximation terms and adaptive tuning laws using quantized states are constructed to compensate for unknown nonaffine nonlinearities and quantization errors.

(ii) In contrast to previous recursive tracker designs using quantized state feedback [33]–[36], this paper firstly deals with nonaffine nonlinearities interacting state variables and inputs in uncertain MIMO nonlinear systems. Moreover, a design difficulty caused by unknown gain matrices derived from the mean value theorem is resolved by introducing new adaptive approximation terms using quantized state feedback, contrary to [33]–[36]. The closed-loop stability based on quantized state feedback is investigated by analyzing the quantization errors.

The rest of the paper is organized as follows. The neural-network-based quantized state feedback tracking problem of MIMO nonlinear pure-feedback systems with state quantizers is described in Section II. The proposed adaptive quantized control design and stability analysis are discussed in Section III. Section IV presents simulation results including a practical example. Finally, we draw our conclusions in Section V.

II. PROBLEM FORMULATION

Consider the following uncertain MIMO block-triangular pure-feedback nonlinear system with external disturbances:

\[
\dot{x}_i = f_i(\bar{x}_i, x_{i+1}) + d_i(t), \quad i = 1, \ldots, n - 1
\]

\[
\dot{x}_n = f_n(\bar{x}_n, u) + d_n(t)
\]

\[
y = x_1
\]

where \(x_i = [x_{i,1}, \ldots, x_{i,m}]^\top \in \mathbb{R}^m\) and \(\bar{x}_i = [x_{i,1}^T, \ldots, x_{i,m}^T]^\top \in \mathbb{R}^{mn}, i = 1, \ldots, n\), are the state vectors, \(y = [y_1, \ldots, y_m]^\top \in \mathbb{R}^m\) is the system output vector, \(u = [u_1, \ldots, u_m]^\top \in \mathbb{R}^m\) is the control input vector, \(f_i(\bar{x}_i, x_{i+1}) = [f_{i,1}(\bar{x}_i, x_{i+1,1}), \ldots, f_{i,m}(\bar{x}_i, x_{i+1,m})]^\top \in \mathbb{R}^m, i = 1, \ldots, n-1\), and \(f_n(\bar{x}_n, u) = [f_{n,1}(\bar{x}_n, u_1), \ldots, f_{n,m}(\bar{x}_n, u_m)]^\top \in \mathbb{R}^m\) are the unknown \(C^1\) nonaffine nonlinear function vectors, and \(d_i(t) \in \mathbb{R}^m, i = 1, \ldots, n\), is the external time-varying disturbance vector.

By applying the mean value theorem to the nonaffine functions \(f_{i,j}(\bar{x}_i, x_{i+1,j})\) and \(f_{n,j}(\bar{x}_n, u_j)\), \(j = 1, \ldots, m\), we obtain [11]

\[
f_{i,j}(\bar{x}_i, x_{i+1,j}) = f_{i,j}(\bar{x}_i, 0) + \frac{\partial f_{i,j}}{\partial x_{i+1,j}}(x_{i+1,j} - 0) (x_{i+1,j} = \xi_{i,j})
\]

\[
f_{n,j}(\bar{x}_n, u_j) = f_{n,j}(\bar{x}_n, 0)
\]
where $\kappa_{i,j} \in (0, x_{i,j+1})$ and $\kappa_{n,j} \in (0, u_j)$.

Then, $f_i(\tilde{x}_i, x_{i+1})$ and $f_n(\tilde{x}_n, u)$ can be rewritten as

$$f_i(\tilde{x}_i, x_{i+1}) = f_i(\tilde{x}_i) + G_i x_{i+1}, \quad i = 1, \ldots, n - 1$$

$$f_n(\tilde{x}_n, u) = f_n(\tilde{x}_n) + G_n u + d_n(t)$$

Then, assuming $\beta_{i,n}(\tilde{x}_i, \tilde{x}_n) = \tilde{f}_n(\tilde{x}_n) = [f_{n1}(\tilde{x}_n), \ldots, f_{nm}(\tilde{x}_n)]^T$, $f_n(\tilde{x}_n) = [f_{n1}(\tilde{x}_n, 0), \ldots, f_{nm}(\tilde{x}_n, 0)]^T$, $G_i(\tilde{x}_i, \tilde{x}_n) = \tilde{f}_i(\tilde{x}_i, x_{i+1}) / \kappa_{i,n}, \kappa_{i,j}, \kappa_{n,j}$, with $\kappa_i = [\kappa_{i1}, \ldots, \kappa_{i,m}]^T$, and $G_n(\tilde{x}_n, \kappa_n) = \tilde{f}_n(\tilde{x}_n, u) / \partial u_{x_n}$ with $\kappa_n = [\kappa_{n1}, \ldots, \kappa_{n,m}]^T$. Here, $G_i$ and $G_n$ are unknown gain matrices.

Using (4) and (5), the uncertain MIMO nonlinear system (1) becomes

$$\dot{x}_i = f_i(\tilde{x}_i) + G_i x_{i+1} + d_i(t), \quad i = 1, \ldots, n - 1$$

$$\dot{x}_n = f_n(\tilde{x}_n) + G_n u + d_n(t)$$

$$y = x_1.$$  

Assumption 1: [37] The matrix $G_i(\cdot)$, $i = 1, \ldots, n$ satisfies $0 < g_{i,m} \leq |\lambda(G_i)| \leq g_{i,m}$ where $g_{i,m} > 0$, and $g_{i,m} > 0$. $G_i(\cdot)$ is eigenvalue operator.

In this study, a network-based control problem using quantized state feedback is considered for system (1). In the network-based control problem, the system (1) and the controller are assumed to be connected through a network with a limited bandwidth. Thus, the measured state feedback information is transmitted to the controller after state quantization. For state quantization, the uniform quantizer is selected as follows:

$$Q(x_{i,j}) = \begin{cases} 
Z_{\mu}, & Z_{\mu} - \frac{\rho}{2} \leq x_{i,j} < Z_{\mu} + \frac{\rho}{2} \\
0, & -\frac{\rho}{2} \leq x_{i,j} < \frac{\rho}{2} \\
-Z_{\mu}, & -Z_{\mu} - \frac{\rho}{2} < x_{i,j} < -Z_{\mu} + \frac{\rho}{2}
\end{cases}$$

where $i = 1, \ldots, n$, and $j = 1, \ldots, m$. $\mu \in \mathbb{Z}^+$, $\rho$ is the quantization level, $Z_1 = 0$, and $Z_{n+1} = Z_{\mu} + \rho$. We use the definition $x_{i,j}^q \triangleq Q(x_{i,j})$ for notation simplicity. Then, using the property of the uniform quantizer, the state quantization error $\mu_{x_{i,j}} \triangleq x_{i,j} - x_{i,j}^q$ and its vector $\mu_{x_{i,j}} \triangleq x_{i,j} - x_{i,j}^q$ satisfy $|\mu_{x_{i,j}}| \leq \rho$ and $||\mu_{x,1}|| \leq \rho \sqrt{m}$, respectively [18] where $x_{i,j}^q = [x_{i,1}^q, \ldots, x_{i,m}^q]^T$.

Remark 1: Owing to the uniformity of the quantization levels and simple structure, uniform quantizers facilitate the analysis of the quantization effect. Therefore, they are frequently utilized in analog-to-digital signal conversion [18]. For this reason, we use uniform quantizers (7) to quantize all measurable states for feedback. However, hysteresis-uniform or logarithmic-uniform quantizers can also be applied to the proposed approach.

Assumption 2: [33] The quantized state vector $x_i^q = [x_{i,1}^q, \ldots, x_{i,m}^q]^T \in \mathbb{R}^m$, $i = 1, \ldots, n$, is available for feedback, rather than the unquantized state vector $x_i$.

Assumption 3: [2] The desired signal vector $y_d \in \mathbb{R}^m$ and its time derivatives $\dot{y}_d$ and $\ddot{y}_d$ are bounded.

**Assumption 4:** The time-varying external disturbance vector $d_i$, $i = 1, \ldots, n$, satisfies $\|d_i\| \leq \bar{d}_i$ with an unknown constant $\bar{d}_i > 0$.

**Lemma 1** [39]: For a Hurwitz matrix $A \in \mathbb{R}^{m \times m}$ and a symmetric positive definite matrix $S \in \mathbb{R}^{m \times m}$, the inequality $\|e^t\| \leq a_1 e^{-b_1 t}$ is ensured where $a_1 = \sqrt{\lambda_{\max}(S)/\lambda_{\min}(S)}$, $b_1 = 1/\lambda_{\max}(S)$, and $\lambda_{\min}(S)$ and $\lambda_{\max}(S)$ are the maximum and minimum eigenvalues of $S$, respectively.

**Problem 1:** The control objective is to design a neural-network-based adaptive quantized state feedback control law $u$ for uncertain MIMO pure-feedback nonlinear systems (1) with state quantizers (7) so that the output vector $y(t)$ tracks the desired trajectory $x_d(t)$, while all the closed-loop signals are bounded.

**Remark 2:** The validity of Assumptions 1–4 is explained as follows:

(i) The matrix $G_i(\cdot)$ plays the role of the coefficient matrix for the virtual and actual control laws in the control design steps. $G_i(\cdot) \neq 0$ should be assumed for controllability, which leads to $0 < g_{i,m} \leq |\lambda(G_i)| \leq g_{i,m}$ by Assumption 1. This implies that $G_i(\cdot)$ is strictly either positive or negative definite. Without loss of generality, it is assumed that $G_i(\cdot) > 0$. Thus, Assumption 1 is reasonable.

(ii) Assumption 2 means that the state quantization problem is considered in this study. Thus, quantized state variables are available for feedback control design. This assumption is given for the problem formulation.

(iii) Assumption 3 implies that the desired signal and its two first derivatives are bounded. This assumption is reasonable for the recursive tracking control design objective.

(iv) Assumption 4 indicates that external disturbances may not grow arbitrarily large. This is common in existing control results.

**Remark 3:** For Problem 1, it is necessary to design a control law and adaptive tuning laws using quantized states in the presence of unknown nonaffine nonlinearities in MIMO form while ensuring the boundedness of quantization errors between the original and quantized signals. Furthermore, although quantized signals are used as inputs for neural network approximators, the boundedness of quantization errors and the closed-loop stability of the proposed neural-network-based control system should be proved. However, the existing adaptive control designs [23]–[32] dealing with input quantization of MIMO nonlinear systems use continuous state feedback information without state quantization. Thus, owing to the presence of quantized state feedback signals, Problem 1 cannot be addressed by the solutions proposed in [23]–[32].

**III. NEURAL-NETWORK-BASED ADAPTIVE QUANTIZED STATE FEEDBACK CONTROL**

**A. RADIAL BASIS FUNCTION NEURAL NETWORKS**

Unknown continuous nonlinear function vectors $N_i(v_i) \in \mathbb{R}^m$, $i = 1, \ldots, n$, can be approximated via radial basis function neural networks (RBFNNs) [40] in the compact set...
\( \Psi_i \subseteq \mathbb{R}^h \) as follows:
\[
N_i(v_i) = \theta_i^T B_i(v_i) + \phi_i(v_i), \tag{8}
\]
where \( v_i \in \Psi_i \) is the input vector of the RBFNN, \( \theta_i = \text{diag}[\theta_{i,1}, \ldots, \theta_{i,m}] \in \mathbb{R}^{m \times m} \) is the ideal weighting matrix, \( \phi_i = [\phi_{i,j}, \ldots, \phi_{i,M}]^T \in \mathbb{R}^{m} \) is the number of neurons, \( \phi_i \in \mathbb{R}^m \), \( i = 1, \ldots, n \) represents an approximation reconstruction error such that \( \|\phi_i\| \leq \tilde{\phi}_i \) with an unknown constant \( \tilde{\phi}_i > 0 \), \( B_i = [B_{i,1}, \ldots, B_{i,m}]^T \in \mathbb{R}^{m \times m} \) is the Gaussian function vector. Using the inherent property of Gaussian basis functions, it is ensured that \( \|B_i\| \leq \tilde{B} \) with a constant \( \tilde{B} > 0 \) [41], [42].

**Assumption 5**: [41] \( \theta_i \) and \( \phi_i \) are bounded as \( \|\theta_i\| \leq \tilde{\theta}_i \) and \( \|\phi_i\| \leq \tilde{\phi}_i \), respectively, where \( \tilde{\theta}_i > 0 \) and \( \tilde{\phi}_i > 0 \) are constants.

\section*{B. ADAPTIVE CONTROL DESIGN USING QUANTIZED STATE FEEDBACK}

The quantized state variables cannot be utilized directly in a Lyapunov-based systematic design because they are discontinuous. Thus, our design strategy is based on (i) designing the intermediate control signals using the quantized state variables in **Step 1**, (ii) expressing the actual adaptive control input vector \( u \) using quantized state feedback in **Step 2**, and (iii) analyzing the quantization errors between quantized and quantized signals to ensure the stability of the closed-loop system in the stability analysis part (see Section III-C).

**Step 1**: For the systematic control design of intermediate control signals, the command-filtered backstepping technique using second-order low-pass filters is employed. The error surfaces are expressed as follows:
\[
\begin{align*}
    z_i &= x_i - x_d \\
    z_{i+1} &= x_{i+1} - \alpha_i \tilde{z}_i \\
    \tilde{\alpha}_i &= \alpha_i - \alpha_i,
\end{align*}
\tag{9}
\]
where \( i = 1, \ldots, n - 1 \), \( z_i = [z_{i,1}, \ldots, z_{i,m}]^T \in \mathbb{R}^m \) and \( z_{i+1} = [z_{i+1,1}, \ldots, z_{i+1,m}]^T \in \mathbb{R}^m \) are error surfaces, \( \alpha_i = [\alpha_{i,1}, \ldots, \alpha_{i,m}]^T \in \mathbb{R}^m \) are intermediate control laws, and \( \alpha_i = [\alpha_{i,1}, \ldots, \alpha_{i,m}]^T \in \mathbb{R}^m \) are their corresponding filtered signals provided by the following second-order low-pass filters:
\[
\begin{align*}
    \alpha_{i,f} &= \beta_i \\
    \beta_i &= -2\xi_{i,f} \beta_i - \omega_i^T \omega_i (\alpha_{i,f} - \alpha_i),
\end{align*}
\tag{10}
\]
with \( \alpha_i(0) = \alpha_i(0), \beta_i(0) = 0 \), and the filter constant matrices \( \xi_{i,f} = \text{diag}[\xi_{i,1}, \ldots, \xi_{i,m}] \) and \( \omega_i = \text{diag}[\omega_{i,1}, \ldots, \omega_{i,m}] \). Here, \( \xi_{i,j} > 0 \) and \( \omega_{i,j} > 0, j = 1, \ldots, m \), denote the damping ratio and natural frequency, respectively. The intermediate control laws \( \alpha_i \) are established as follows.

(i) The time derivative of \( z_i \) along (6) is given by
\[
\dot{z}_i = f_1 + G_i x_2 + d_1 - \tilde{x}_d,
\tag{11}
\]

Let us consider the Lyapunov function \( V_1 \) as follows:
\[
V_1 = \frac{1}{2g_{11}^m} z_i^T z_i.
\tag{12}
\]
Differentiating \( V_1 \) with respect to time yields
\[
\dot{V}_1 \leq z_i^T \left( N_1 + \frac{g_{11}^m}{g_{11}^m} x_2 + \frac{d_1}{g_{11}^m} \right),
\tag{13}
\]
where \( N_1(v_i) = \langle f_1 - \tilde{x}_d \rangle / g_{11}^m, \ v_i \rangle = [x_i^T, \tilde{x}_d^T]^T \). Using (8), the unknown function \( N_1 \) is approximated by \( N_i(v_i) = \theta_i^T B_i(v_i) + \phi_i(v_i) \). Then, (13) becomes
\[
\dot{V}_1 \leq z_i^T \left( \theta_i^T B_i + \phi_i + \frac{G_i}{g_{11}^m} x_2 + \frac{d_1}{g_{11}^m} \right).
\tag{14}

From Assumptions 1 and 5, it holds that
\[
\begin{align*}
    z_i^T \theta_i^T B_i &\leq \frac{g_{11}^m}{g_{11}^m} z_i^T z_i + \frac{g_{11}^m}{4g_{11}^m} \|B_i\|^2 \|\theta_i\|^2 \\
    &\leq \frac{1}{g_{11}^m} z_i^T G_i z_i + \frac{g_{11}^m}{g_{11}^m} \|B_i\|^2 W_1,
\end{align*}
\tag{15}
\]
where \( W_1 = (g_{11}^m/4g_{11}^m)^{1/2} \). Then, (13) becomes
\[
\dot{V}_1 \leq \frac{1}{g_{11}^m} z_i^T G_i (z_i + z_2 + \tilde{\alpha}_i + \alpha_i) + z_i^T \left( \phi_i + \frac{d_1}{g_{11}^m} \right) + \frac{g_{11}^m}{g_{11}^m} \|B_i\|^2 W_1.
\tag{16}
\]
The intermediate signal \( \alpha_1 \) is designed as follows
\[
\alpha_1 = -\left( \zeta_1 + 1 \right) z_1 - \frac{\|B_i\|^2 \tilde{W}_1}{(z_1 z_1 + \tilde{\epsilon})} - \tilde{\delta}_1 \tanh \left( \frac{z_1}{\epsilon_1} \right),
\tag{17}
\]
where \( \zeta_1 \) is a design parameter, \( \tanh(z_1/\epsilon_1) = [\tanh(z_1/\epsilon_1), \ldots, \tanh(z_1/\epsilon_1)]^T \in \mathbb{R}^m \); \( \epsilon_{i,j} > 0, j = 1, \ldots, m \), are design parameters, \( \tilde{\epsilon} \) is a design parameter satisfying \( \tilde{\epsilon} \geq 1/4 \), and \( \tilde{W}_1 \) is the estimate of \( W_1 \), and \( \tilde{\delta}_1 \) is the estimate of an unknown constant \( \delta_1 > 0 \), which is defined subsequently.

Substituting (17) into (16) gives
\[
\dot{V}_1 \leq -\frac{1}{g_{11}^m} z_i^T G_i z_i + \frac{1}{g_{11}^m} z_i^T G_i (z_2 + \tilde{\alpha}_i) - \frac{z_i^T G_i(z_j + \tilde{\alpha}_i)}{g_{11}^m (z_i z_i + \tilde{\epsilon})} \|B_i\|^2 (W_1 + \tilde{W}_1)
\frac{g_{11}^m}{g_{11}^m} z_i^T G_i (z_1 + \tilde{\epsilon}) \|B_i\|^2 W_1 + \frac{g_{11}^m}{g_{11}^m} \|B_i\|^2 W_1 \right) + \frac{1}{g_{11}^m} z_i^T G_i \tilde{\delta}_1 + \tilde{\delta}_1 \tanh \left( \frac{z_1}{\epsilon_1} \right),
\tag{18}
\]
where \( \tilde{\delta}_1 = \delta_1 - \delta_1 \) and \( \tilde{W}_1 = W_1 - W_1 \) are the estimation errors.

Then, using \( -z_i^T G_i z_i \leq -g_{11}^m z_i^T z_i \), we have
\[
\begin{align*}
    -\frac{z_i^T G_i(z_j + \tilde{\alpha}_i)}{g_{11}^m (z_i z_i + \tilde{\epsilon})} \|B_i\|^2 W_1 + \frac{g_{11}^m}{g_{11}^m} \|B_i\|^2 W_1 = -\frac{z_i^T G_i z_i}{g_{11}^m (z_i z_i + \tilde{\epsilon})} \|B_i\|^2 W_1 + \frac{g_{11}^m}{g_{11}^m} \|B_i\|^2 W_1
\end{align*}
\]
Let us design the intermediate signal $\alpha_i$ as
\[
\alpha_i = -(\zeta_i + 1)z_i - \frac{\|B_i\|^2 \tilde{W}_i}{\zeta_i z_i + \bar{\epsilon}} - \delta_i \tanh \left( \frac{z_i}{\epsilon_i} \right)
\]  
Substituting (26) into (25) and using the inequality as in (19) yields
\[
\dot{V}_i \leq -\frac{1}{g_{lm}} \zeta_i z_i^T G_i z_i + \frac{1}{g_{lm}} z_i^T G_i (z_i + \bar{\alpha}_i) \\
- \frac{1}{g_{l(i-1)m}} z_i^T G_{i-1} z_i + \frac{g_{lm}}{g_{lm}} \|B_i\|^2 \tilde{W}_i \\
- \frac{z_i^T G_i z_i}{g_{(i-1)m}(z_i z_i + \bar{\epsilon}) \|B_i\|^2 \tilde{W}_i} + \frac{d_i}{g_{lm}} \phi_i
\]
where $\tilde{\delta}_i = \delta_i - \delta_i$ and $\tilde{W}_i = \tilde{W}_i - W_i$ are the estimation errors. (iii) The time derivative of $z_n$ along (6) is given by
\[
\dot{z}_n = f_n + G_n u - \bar{\alpha}_{n-1, f} + d_n.
\]
Consider the Lyapunov function $V_n = (1/(2g_{nm}))z_n^T z_n$. Differentiating $V_n$ with respect to time yields
\[
\dot{V}_n = \frac{1}{g_{nm}} z_n^T (f_n + G_n u - \beta_{n-1} + d_n).
\]
Adding and subtracting $z_{n-1}^T G_{n-1} z_{n-1}/g_{(n-1)m}$, (29) becomes
\[
\dot{V}_n = z_n^T \left( N_n + G_n u + \frac{d_n}{g_{nm}} \right) - \frac{1}{g_{(n-1)m}} z_{n-1}^T G_{n-1} z_n
\]
where $N_n(v_n) = (f_n - \beta_{n-1})/g_{nm} + G_n^T z_{n-1}/g_{(n-1)m}$; $v_n = [x_n^T, z_{n-1}^T, \beta_{n-1}^T]^T$. Using (8), the unknown function $N_n$ is approximated as $N_n(v_n) = \theta_n^T B_n(v_n) + \phi_n(v_n)$. Then, similar to (15), it holds that
\[
z_n^T \theta_n^T B_n \leq \frac{1}{g_{nm}} z_n^T G_n z_n + \frac{g_{nm}}{g_{nm}} \|B_n\|^2 W_n
\]
where $W_n = (g_{nm}^2 / 4g_{nm}^2) \bar{	heta}_n^2$. Using (30), (31) becomes
\[
\dot{V}_n = \frac{1}{g_{nm}} z_n^T G_n (\mu_n + z_n + \nu + z_n^T (\phi_n + \frac{d_n}{g_{nm}}))
\]
\[
- \frac{1}{g_{(n-1)m}} z_{n-1}^T G_{n-1} z_n + \frac{g_{nm}}{g_{nm}} \|B_n\|^2 W_n.
\]
Let us design the intermediate signal as
\[
\nu = - (\zeta_n + 1)z_n - \frac{\|B_n\|^2 \tilde{W}_n}{(z_n z_n + \bar{\epsilon})} - \delta_n \tanh \left( \frac{z_n}{\epsilon_n} \right)
\]  
where $\zeta_n$ is a design parameter, $\tanh(z_n/\epsilon_n) = [\tanh(z_n/\epsilon_{n,1}), \ldots, \tanh(z_n/\epsilon_{n,m})]^T \in \mathbb{R}^m$; $\epsilon_{n,j} > 0$, $j = 1, \ldots, m$, are design parameters, and $\tilde{W}_n$ and $\tilde{\delta}_n$ are estimates of $W_n$ and an unknown constant $\delta_n > 0$ to be defined later, respectively.
where \(\hat{\delta}_n = \hat{\delta}_n - \delta_n\) and \(\hat{W}_n = \hat{W}_n - W_n\) are the estimation errors.

**Step 2:** In this step, we present a quantized-state-based control law \(u\) based on the structures of the error surfaces and the internal signals designed in Step 1. Owing to the recursive design property of a quantized-state-based control law, all error surfaces and internal signals designed in Step 1 are redefined using quantized states.

The error surfaces using state quantization are defined as

\[
\begin{align*}
\zeta_1^* &= x_1^q - x_d \\
\zeta_{i+1}^* &= x_{i+1}^q - \alpha_{i,f}^* \end{align*}
\]

where \(i = 1, \ldots, n - 1\), and \(\alpha_{i,f}^*\) are the command-filtered signals of the virtual control laws \(\alpha_i^*\) using quantized states expressed as

\[
\begin{align*}
\dot{\alpha}_{i,f}^* &= \beta_i^*, \\
\dot{\beta}_i^* &= -2\xi_i \bar{w}_i \beta_i^* - \bar{w}_i \bar{w}_i (\alpha_{i,f}^* - \alpha_i^*)
\end{align*}
\]

with \(\alpha_{i,f}^*(0) = \alpha_i^*(0)\) and \(\beta_i^*(0) = 0\).

Then, we introduce the quantized-state-feedback-based virtual control laws \(\alpha_i^*\) and the adaptive actual control law \(u\) as follows:

\[
\begin{align*}
\alpha_i^* &= -(\xi_i + 1) \zeta_i^* - \frac{\zeta_i^*}{(\zeta_i^*)^T \zeta_i^* + \epsilon} \|B_i^*\|^2 \hat{W}_i - \delta_i \tanh \left( \frac{\zeta_i^*}{\epsilon_i} \right) \\
u &= -(\xi_n + 1) \zeta_n^* - \frac{\zeta_n^*}{(\zeta_n^*)^T \zeta_n^* + \epsilon} \|B_n^*\|^2 \hat{W}_n - \delta_n \tanh \left( \frac{\zeta_n^*}{\epsilon_n} \right) \\
\dot{\hat{W}}_j &= \Gamma_{W,j}(\|\zeta_j^*\|^2 \|B_j^*\|^2 - \sigma_{W,j}\|\zeta_j^*\|^2 \hat{W}_j) \\
\dot{\hat{W}}_k &= \Gamma_{W,k}(\|\zeta_k^*\|^2 \|B_k^*\|^2 - \sigma_{W,k}\|\zeta_k^*\|^2 \hat{W}_k)
\end{align*}
\]

for \(k = 2, \ldots, n - 1\). Here, \(A_j\) are Hurwitz matrices due to \(\xi_{j,i} > 0\) and \(\sigma_{j,i} > 0\), \(l = 1, \ldots, m\). Thus, for any matrix \(Q_j\) with \(Q_j > 0\), \(A_j^T S_j + S_j A_j = -Q_j\) is ensured with a symmetric matrix \(S_j > 0\).

**Lemma 2:** For the adaptive laws \((40)\) and \((41)\), there exist compact sets \(\Psi_{W,i} = \{\hat{W}_i + \Delta \omega_{W,i}\}\) with a constant \(\Omega_{W,i}\) and \(\Psi_{\delta,i} = \{\delta_i \mid \delta_i \leq \Omega_{\delta,i}\}\) with a constant \(\Omega_{\delta,i}\) such that \(\hat{W}_i(t) \in \Psi_{W,i}\) and \(\delta_i(t) \in \Psi_{\delta,i}\) for \(t \geq 0\) provided that \(\hat{W}_i(0) \in \Psi_{W,i}\) and \(\delta_i(0) \in \Psi_{\delta,i}\), respectively, where \(i = 1, \ldots, n\).
Proof: To prove the boundedness of \( \dot{\hat{W}}_i \), consider a Lyapunov function candidate \( V_{W,i} = (1/2\Gamma_{W,i})\hat{W}_i^2 \). Then, from \( ||\theta_i|| \leq \tilde{\theta}_i \), \( ||B_i|| \leq \tilde{B}_i \), and \( ||B_i^*|| \leq \tilde{B}_i \), the time derivative of \( V_{W,i} \) is obtained as

\[
\dot{V}_{W,i} = \|z^*_i\|^2 \hat{W}_i (\|B_i^*\|^2 - \sigma_{W,i} \hat{W}_i) \\
\leq \|z^*_i\|^2 \hat{W}_i (\tilde{B}_i^2 + \sigma_{W,i} \hat{W}_i) - \sigma_{W,i} \hat{W}_i,\quad (43)
\]

where \( w_i = (s^2_{\text{SM}}/4g^2_{\text{SM}}) \). Therefore, it is ensured that \( \dot{V}_{W,i} < 0 \) when \( |\hat{W}_i| > \Omega_{W,i} \) with \( \Omega_{W,i} = \frac{1}{2}(\tilde{B}_i^2 + \sigma_{W,i} \hat{W}_i) / \sigma_{W,i} \). Thus, \( V_{W,i} \) decreases when \( W_i(t) \notin \Psi_{W,i} \), and \( W_i(t) \) remains within \( \Psi_{W,i} \).

Let us show the boundedness of \( \tilde{\delta}_i \) by considering \( V_{\delta,i} = (1/2\Gamma_{\delta,i})\tilde{\delta}_i^2 \). From \( ||\tanh(z^*/\epsilon_i)|| \leq \sqrt{m} \) and \( \tilde{\delta}_i = \delta_i + \tilde{\delta}_i \), it holds that

\[
\dot{V}_{\delta,i} \leq \|\tilde{\delta}_i\|^2 (\sqrt{m} + \sigma_{\delta,i} \delta_i - \sigma_{\delta,i} \tilde{\delta}_i).\quad (44)
\]

Therefore, it is ensured that \( \dot{V}_{\delta,i} < 0 \) when \( |\tilde{\delta}_i| > \Omega_{\delta,i} \) with \( \Omega_{\delta,i} = \sqrt{m} / \sigma_{\delta,i} \). Thus, \( V_{\delta,i} \) decreases when \( \delta_i(t) \notin \Psi_{\delta,i} \), and \( \delta_i(t) \) remains within \( \Psi_{\delta,i} \). If \( \delta_i(0) \notin \Psi_{\delta,i} \) and \( \delta_i(t) \in \Psi_{\delta,i} \) for all \( t \geq 0 \), this completes the proof of this lemma.

Lemma 3: Define the quantization error vectors of the closed-loop signals as

\[
\begin{align*}
\mu_{z,i} &= z_i - z^*_i, \\
\mu_{\alpha,j} &= \alpha_j - \alpha^*_j, \\
\mu_{\alpha,j,f} &= \alpha_{j,f} - \alpha^*_{j,f}, \\
\mu_{\beta,j} &= \beta_j - \beta^*_j
\end{align*}
\]

where \( i = 1, \ldots, n \) and \( j = 1, \ldots, n - 1 \), and consider the quantization errors of the control input \( \mu_u = u - v \). Then, there exist positive constants \( \Delta_{z,i}, \Delta_{\alpha,j}, \Delta_{\beta,j}, \) and \( \Delta_u \) such that \( ||\mu_{z,i}|| \leq \Delta_{z,i}, ||\mu_{\alpha,j}|| \leq \Delta_{\alpha,j}, ||\mu_{\beta,j}|| \leq \Delta_{\beta,j} \), and \( ||\mu_u|| \leq \Delta_u \), respectively, where \( \mu_{\alpha,j} = [\mu_{\alpha,j,f}, \mu_{\beta,j}]^T \).

Proof: We prove this lemma following a recursive approach.

(i) From the property \( ||x_{j,i}|| \leq \rho \sqrt{m} \) and \( z_{\tau,1} = z_1 - z^*_1 \), it holds that

\[
||\mu_{\tau,1}|| = ||x_{\tau,1}|| \leq \rho \sqrt{m} \leq \tilde{\delta}_1. \quad (45)
\]

Lemma 2 leads to \( |\hat{W}_1| \leq \tilde{\Omega}_{W,1} \) and \( |\tilde{\delta}_1| \leq \tilde{\Omega}_{\delta,1} \) where \( \tilde{\Omega}_{W,1} = \max\{|\hat{W}_1(0)|, \Omega_{W,1}\} \) and \( \Omega_{\delta,1} = \max\{|\tilde{\delta}_1(0)|, \Omega_{\delta,1}\} \). From the boundedness of \( W_1 \) and \( \delta_1 \), there exist unknown constants \( \tilde{W}_1 \) and \( \tilde{\delta}_1 \) that satisfy \( |\hat{W}_1| \leq \tilde{W}_1 \) and \( |\tilde{\delta}_1| \leq \tilde{\delta}_1 \). Using (17) and (38), we obtain

\[
\mu_{\alpha,j} = -((\zeta_1 + 1)(z_1 - z^*_1) - \frac{z_1}{\max(z_1, \tilde{\epsilon})} ||B_1||^2 \\
- \frac{z_1^*}{(z_1^* + \tilde{\epsilon})} ||B_1||^2) \tilde{W}_1 \\
- \tilde{\delta}_1 \left( \tanh \left( \frac{z_1}{\epsilon_1} \right) - \tanh \left( \frac{z_1}{\epsilon_1} \right) \right). \quad (46)
\]

Here, \( ||z_1/(z_1^* + \tilde{\epsilon})|| \leq 1 \) is satisfied because of \( \tilde{\epsilon} \geq 1/4 \). Using the inequalities \( ||B_i - B_i^*|| \leq 2\tilde{B}_i \) and
\[\| \tan(\frac{z_i}{\epsilon_i}) - \tan(\frac{z_n}{\epsilon_n}) \| \leq 2\sqrt{m}, \ i = 1, \ldots, n, \]

\[\| \mu_{x,i} \| \leq (\zeta_1 + 1)\Delta_{\chi,1} + 2\tilde{B}_1 \tilde{W}_1 + 2\tilde{\delta}_1 \sqrt{m} \leq \Delta_{\alpha,1}. \]  

(47)

From (10) and (37), the time derivative of the quantization error \( \mu_{x,i} = [\mu_{x,1,i}, \mu_{x,2,i}]^T \) is given by

\[\dot{\mu}_{x,i} = A_1 \mu_{x,i} + H_1 \mu_{x,1} \]  

(48)

where \( A_1 = \begin{bmatrix} 0 & I \\ -\omega_1 & -2\bar{\epsilon}_1 \omega_1 \end{bmatrix} \) and \( H_1 = [0, \omega_1^T \omega_1]^T \).

Thus, the solution of (48) is obtained as

\[\mu_{x,i}(t) = e^{A_1 t} \mu_{x,i}(0) + \int_0^t e^{A_1(t-\tau)} H_1 \mu_{x,1}(\tau) d\tau. \]  

(49)

From \( \| \mu_{x,1} \| \leq \Delta_{\alpha,1} \), we have that for all \( t \geq 0 \),

\[\| \mu_{x,i}(t) \| \leq e^{A_1 t} \| \mu_{x,i}(0) \| + \Delta_{\alpha,1} \| H_1 \| A_1^{-1} \| I - e^{A_1 t} \|. \]  

(50)

From Lemma 1, the inequality \( e^{A_1 t} \| \mu_{x,i}(0) \| \leq a_1 e^{-b_1 t} \) is ensured where \( a_1 > 0 \) and \( b_1 > 0 \) are constants. Thus, (50) is expressed as

\[\| \mu_{x,i}(t) \| \leq a_1 \| \mu_{x,1}(0) \| + \Delta_{\alpha,1} \| H_1 \| A_1^{-1} \| (1 + a_1) \Delta_{\chi,1}. \]  

(51)

It is satisfied that \( \| \mu_{x,1,j} \| \leq \Delta_{\chi,1} \) and \( \| \mu_{x,j} \| \leq \Delta_{\chi,j} \).

(ii) Owing to \( \| \mu_{x,j} \| \leq \rho \sqrt{m}, \mu_{z,j} \) is bounded as

\[\| \mu_{z,j} \| \leq \rho \sqrt{m} + \rho \sqrt{m} \Delta_{\chi,j}. \]

(52)

where \( \Delta_{\chi,j} \equiv (\zeta_j + 1)\Delta_{\chi,j} + 2\tilde{B}_j \tilde{W}_j + 2\tilde{\delta}_j \sqrt{m} \) with positive unknown constants \( \tilde{W}_j \) and \( \tilde{\delta}_j \) satisfying \( |\tilde{W}_j| \leq \tilde{W} \) and \( |\tilde{\delta}_j| \leq \tilde{\delta}_j \), respectively. Similar to (48)–(51), there exists a constant \( \Delta_{\chi,j} \) such that \( \| \mu_{x,j,i} \| \leq \Delta_{\chi,j} \) and \( \| \mu_{x,j} \| \leq \Delta_{\chi,j} \).

(iii) Similar to (52), it is satisfied that

\[\| \mu_{x,n} \| \leq \Delta_{\chi,n} \]

(54)

where \( \Delta_{\chi,n} = \rho \sqrt{m} + \Delta_{\chi,n-1} \). Then, from (33) and (39), we obtain

\[\mu_u = -((\zeta_n + 1)(z_n - z_n^\circ) - (z_n^\circ)^2 - ((z_n^\circ)^2 + z_n^\circ^2 - \epsilon_n^\circ)^2)\tilde{W}_n \]

\[\tilde{\delta}_n \left( \tanh \left( \frac{z_n}{\epsilon_n} \right) - \tanh \left( \frac{z_n^\circ}{\epsilon_n} \right) \right). \]  

(55)

Then, using \( \| z_n/(z_n^\circ + \tilde{\delta}_n^\circ) \| \leq 1 \), \( \mu_u \) is bounded as

\[\| \mu_u \| \leq \Delta_u \]

(56)

where \( \Delta_u \equiv (\zeta_n + 1)\Delta_{\chi,n} + 2\tilde{B}_n \tilde{W}_n + 2\tilde{\delta}_n \sqrt{m} \) with positive unknown constants \( \tilde{W}_n \) and \( \tilde{\delta}_n \) satisfying \( |\tilde{W}_n| \leq \tilde{W} \) and \( |\tilde{\delta}_n| \leq \tilde{\delta}_n \), respectively. This completes the proof. \( \blacksquare \)

Choose the overall Lyapunov function candidate \( V \) as

\[V = \sum_{i=1}^{n} V_i + \sum_{j=1}^{n-1} \chi_j^T S_j \chi_j \]

(57)

where \( S_j > 0 \) is a symmetric matrix.

**Remark 6**: Contrary to the existing neural-network-based adaptive control approaches considering state quantization [34]–[36], this paper deals with the problem of unknown control coefficient function matrices \( G_i \) in the control design procedure. Specifically, the minimal parameter technique is employed to tune the unknown parameters \( W_i \), \( i = 1, \ldots, n \) including the norm of the weights of RBFNNs. The minimal parameter technique is commonly used in the form \( z_i \| B_i \|^2 \hat{W}_i \) in the existing studies for uncertain nonlinear pure-feedback systems [12], [15], [16], [28], [29]. However, this form cannot be directly adopted in our quantized state feedback controller because the boundedness of the quantization errors \( z_i \| B_i \|^2 \hat{W}_i - z_i^\circ \| B_i^\circ \|^2 \hat{W}_i \) cannot be analyzed based on the boundedness of \( \mu_{z,j} \) and \( B_i^\circ \) in Lemma 3. Thus, we introduce adaptive neural compensation terms \( z_i \| B_i \|^2 \hat{W}_i / (z_i^\circ + \tilde{\delta}_i) \) in the proposed tracker (i.e., (38) and (39)) and the inequality \( z_i \| B_i \|^2 \hat{W}_i / (z_i^\circ + \tilde{\delta}_i) \leq \tilde{B}_i \tilde{W}_i \) is employed in the proof of Lemma 3.

**Theorem 1**: Consider an uncertain MIMO pure-feedback nonlinear system (1) with state quantizers (7) where state variables and control inputs are fully interconnected in the block-triangular pure-feedback form. Then, for any initial conditions satisfying \( V(0) \leq \psi \) with a constant \( \psi > 0 \), the neural-network-based quantized adaptive tracking scheme consisting of (38)–(41) ensures uniform ultimate boundedness of all closed-loop signals using quantized feedback and the convergence of the tracking error \( z_1 \) to an arbitrarily small neighborhood of the origin.

**Proof**: Substituting (20), (27), (35), and (42) into the time derivative of \( V \) yields

\[\dot{V} \leq -\sum_{i=1}^{n} \frac{1}{g_{IM}} z_i \hat{G}_i z_i - \sum_{j=1}^{n-1} \chi_j^T Q_j \chi_j + 2 \sum_{j=1}^{n} \chi_j^T S_j H P_j + \sum_{j=1}^{n-1} \frac{1}{g_{IM}} z_j \hat{G}_j \hat{\delta}_j \]

\[+ \frac{1}{g_{IM}} z_i \tilde{G}_i \hat{\delta}_i \sum_{i=1}^{n} \frac{1}{g_{IM}} z_i \hat{G}_i \hat{\delta}_i \tanh \left( \frac{z_i}{\epsilon_i} \right) + \frac{1}{g_{IM}} z_i \hat{G}_i \hat{\delta}_i \tanh \left( \frac{z_i}{\epsilon_i} \right) \]

\[+ \frac{1}{g_{IM}} \tilde{B}_i \tilde{W}_i \]

(58)
where

\[ \ddot{\delta}_j = \frac{1}{g_{jm}} \left( g_{jm} \dot{\phi}_j + d_j - \frac{G_z}{z_j^*} B_j^T \bar{W}_j \right) \]

\[ \ddot{\delta}_n = \frac{1}{g_{nm}} \left( g_{nm} \dot{\phi}_n + d_n - \frac{G_z}{z_n^*} B_n^T \bar{W}_n \right) + G_n \mu_n \]

with \( j = 1, \ldots, n - 1 \). From Assumptions 4 and 5, and Lemma 2, there exist positive unknown constants \( \delta_i, \delta_i, \dot{B}_i, \bar{B}_i, \) and \( \Omega_{W,i} \), such that \( \| \dot{\phi}_i \| \leq \delta_i, \| d_i \| \leq \delta_i, \| B_i \| \leq \dot{B}_i \) and \( \| \bar{W}_i \| \leq \Omega_{W,i}, i = 1, \ldots, n \) and \( z_j/(z_j^* + \bar{e}) \) satisfies \( \| z_j^*/(z_j^* + \bar{e}) \| \leq 1 \) for any positive constants \( \bar{e} \geq 1 \). Then, \( \delta_i, i = 1, \ldots, n, \) are defined as

\[ \| \ddot{\delta}_j \| \leq \frac{1}{g_{jm}} \left( g_{jm} \dot{\phi}_j + d_j + g_{jm} \bar{B}_j^T \Omega_{W,j} \sqrt{m} \right) \leq \delta_j \]

\[ \| \ddot{\delta}_n \| \leq \frac{1}{g_{nm}} \left( g_{nm} \dot{\phi}_n + d_n + g_{nm} \bar{B}_n^T \Omega_{W,n} \sqrt{m} + g_{nm} \Delta_n \right) \leq \delta_n \]

where \( j = 1, \ldots, n - 1 \). From (59) and (60), we obtain the following inequality

\[ \frac{g_{jm}}{g_{jm}^T} \delta_j = \frac{1}{8} \frac{g_{jm}}{g_{jm}^T} \delta_j \tanh \left( \frac{z_j}{\varepsilon_i} \right) \]

\[ \leq \frac{g_{jm}}{g_{jm}^T} \delta_j \left( \tanh \left( \frac{z_j}{\varepsilon_i} \right) \right) \]

\[ \sum_{j=1}^{m} \frac{0.2785 \varepsilon_i \delta_i} \]

Using (61), (58) becomes

\[ \dot{V} \leq -\sum_{i=1}^{m} g_{jm} \varepsilon_i z_i \bar{z}_i - \sum_{j=1}^{n-1} q_{jm} \| x_j \|^2 \]

\[ + 2 \sum_{j=1}^{n-1} q_{jm} \| x_j \|^2 \]

\[ - \frac{1}{g_{jm}^T} \delta_j \tanh \left( \frac{z_j}{\varepsilon_i} \right) \]

\[ + \frac{m}{g_{jm}} \sum_{i=1}^{m} \frac{0.2785 \varepsilon_i \delta_i} \]

where \( q_{jm} \) is the minimum eigenvalue of \( Q_j \). Since \( d_j, \bar{W}_i, \) and \( \delta_j \) are bounded, there exist positive functions \( \bar{P}_j \) such that

\[ \| P_i \| (z_i, \bar{a}_i, \bar{x}_i, \bar{W}_i, \Delta_i) \leq \bar{P}_i \]

\[ \| P_k \| (z_k, \bar{a}_k, \bar{x}_k, \bar{W}_k, \Delta_k) \leq \bar{P}_k \]

where \( k = 2, \ldots, n - 1 \). Let us denote the compact sets \( F_j \in \mathbb{R}^{(3h+1)m}, j = 1, \ldots, n - 1 \), and \( F_d \in \mathbb{R}^{nm} \) as

\[ F_j = \left\{ \sum_{j=1}^{n-1} z_j + 2 \sum_{j=1}^{n-1} x_j^T \right\} \mathbb{S}_{n} \left( I \leq 2 \psi \right), \text{and} \ F_d = \left\{ x_d^T x_d + \bar{x}_d^T \bar{x}_d + \bar{x}_d^T \bar{x}_d + \zeta _d \right\} \]
i = 1, \ldots, n - 1, which subsequently increases ζ. Consequently, the compact set \( \Upsilon \) is then reduced.

(iv) Increasing the tuning gains \( \Gamma_{W,i} \) and \( \Gamma_δ, i = 1, \ldots, n \) and fixing \( σ_{W,j} \) and \( σ_δ,j \) as small values help to increase the learning speed of the estimated vectors \( \hat{W}_i \) and parameters \( \hat{δ}_j \).

Remark 8: In [43], a fuzzy adaptive output feedback control approach was presented for MIMO nonlinear systems with full-states prescribed performance in finite-time. In [44], a finite-time adaptive quantized control problem was investigated for stochastic systems in presence of input quantization. The finite-time controllers designed in [43], [44] are based on non-quantized state variables (i.e., continuous state feedback information). To apply the proposed state-quantized design approach to the finite-time control problem, a finite-time control design ensuring bounded quantization errors, as reported in Lemma 3, should be newly developed. Therefore, it will be interesting to address the finite-time control problem based on quantized state feedback of MIMO nonlinear pure-feedback systems in future studies.

IV. SIMULATION RESULTS

To demonstrate the effectiveness of our theoretical tracking strategy in the presence of state quantization, we present two examples including interconnected inverted pendulums. In addition, we compare the tracking performance of the proposed state-quantized controller and the existing tracking controller [11] designed without state quantization.

Example 1: The following MIMO nonlinear system is considered:

\[ \begin{align*}
\dot{x}_1 &= f_1(x_1, x_2) + d_1 \\
\dot{x}_2 &= f_2(x_2, u) + d_2 \\
y_1 &= x_1
\end{align*} \]

where \( x_1 = [x_{1,1}, x_{1,2}]^T, x_2 = [x_{2,1}, x_{2,2}]^T \), and

\[ f_1(x_1, x_2) = \begin{bmatrix}
4 + \sin(x_{1,1}x_{1,2})x_{2,1} + 0.3 \cos(x_{2,1}) \\
2 + \cos(x_{1,1}x_{1,2})x_{2,2} + 0.7 \sin(x_{2,2})
\end{bmatrix} \]
\[
f_2(\dot{x}_2, u) = \left[ x_2, 2e^{-x_1,1}x_1^2, 1 + (2 + x_1^2,2)u_1 + 0.5 \cos(u_1) \right] \\
d_1 = \begin{bmatrix} 0.15 \cos(0.5t) \\ 0.15 \sin(0.5t) \end{bmatrix}, \quad d_2 = \begin{bmatrix} 0.1 \cos(t) \\ 0.1 \sin(t) \end{bmatrix}.
\]

Here, the unknown nonaffine nonlinearities \(f_1\) and \(f_2\) include the interactions of the state variables and control inputs. The desired signal vector is set to \(x_d = [-0.3 \sin(0.5t) + 0.5 \cos(0.25t + \pi/3), 0.3 \sin(0.5t) + 0.5 \cos(0.25t)]^T\). The initial conditions of the state variables are set as \(x_1 = [0, 0]^T\) and \(x_2 = [0, 0]^T\). The quantization level is set to \(\rho = 0.005\). The design parameters of the proposed state-quantized adaptive tracker are chosen to be \(\zeta_1 = 5, \zeta_2 = 7, \Gamma_{W,i} = 3, \Gamma_{d,i} = 1.5, \sigma_{W,i} = 0.01, \sigma_{d,i} = 0.1, \epsilon_{i,1} = \epsilon_{i,2} = 0.08, \delta = 0.25, \xi_{1,1} = \xi_{1,2} = 0.707, \omega_{1,1} = 80, \) and \(\omega_{1,2} = 80\) where \(i = 1, 2\). The control gains and weight tuning parameters of the existing adaptive tracker [11] for MIMO pure-feedback nonlinear systems. Fig. 4 shows the control inputs \(u_1\) and \(u_2\) of the proposed approach. The estimates of \(W_i\) and \(\delta_i, i = 1, 2\) of the proposed approach are depicted in Fig. 5. These results demonstrate that satisfactory tracking performance is achieved by the proposed neural-network-based quantized state feedback tracker while ensuring that all the state variables and tracking errors are bounded.

**Example 2:** In this example, two inverted pendulums interconnected by a spring are taken as an example to verify the effectiveness of the proposed control strategy. The model is expressed as follows [45]:

\[
\begin{align*}
J_1\ddot{\theta}_1 &= m_1gL_p \sin(\theta_1) - 0.5S_iL_p(L_d - S_i) \cos(\theta_1 - \theta_0) + u_1 \\
J_2\ddot{\theta}_2 &= m_2gL_p \sin(\theta_2) - 0.5S_iL_p(L_d - S_i) \cos(\theta_2 - \theta_0) + u_2
\end{align*}
\]

(66)

where \(\theta_1\) and \(\theta_2\) are pendulum angular positions, \(u_1\) and \(u_2\) are control torques, \(m_1 = 1.5\) and \(m_2 = 1.2\) are the masses, \(L_p = 0.4\) m is the pendulum length, \(J_1 = m_1L_p^2\) and \(J_2 = m_2L_p^2\) are the moments of inertia, \(D = 0.3\) m denotes the ground distance between two pendulums, \(S_i = 45\) N/m and \(S_i = 0.5\) m represent the spring constant and spring natural length, respectively, and \(L_d\) is the distance between the connection points, which is expressed as follows

\[
L_d = \sqrt{D^2 + dL_p^2\sin(\theta_1 - \sin(\theta_2) + \frac{L_p^2}{2}(1 - \cos(\theta_2 - \theta_1)))}.
\]

The relative angular position \(\theta_0\) can be defined as

\[
\theta_0 = \tan^{-1}\left(\frac{0.5L_p(\cos(\theta_2 - \cos(\theta_1))}{D + 0.5L_p(\sin(\theta_1 - \sin(\theta_2))}\right).
\]

Let us define the state variables \(x_{1,j} = \theta_j\) and \(x_{2,j} = \dot{\theta}_j\), and assume that the nonaffine nonlinear uncertainties \(\Delta f_{1,j}\) and \(\Delta f_{2,j}\) and the external disturbances \(d_{1,j}\) and \(d_{2,j}, j = 1, 2\) influence the system, as reported in [46]. The dynamics of (66) can then be rewritten as

\[
\dot{x}_{1,1} = f_{1,1}(x_1, x_{2,1}) + d_{1,1}
\]
\[ \dot{x}_1 = f_1(x_1, x_2, u_1) + d_{1,1}, \]
\[ \dot{x}_2 = f_2(x_1, u_1) + d_{2,2}, \]

where \( x_1 = [x_{11}, x_{12}]^T, x_2 = [x_{21}, x_{22}]^T, \sum = [x_1^T, x_2^T]^T, \)

\[ f_1 = x_{21} + \Delta f_1(x_1, x_2), \]
\[ f_2 = J_2^{-1}[m_2 g L_p \sin(x_{11}) - 0.5 S_x L_p \cos(x_{11} - \theta_0) \times (L_d - \delta_1) + u_1 + \Delta f_2(x_2, u_1)] \]
\[ f_2 = J_2^{-1}[m_2 g L_p \sin(x_{12}) - 0.5 S_x L_p \cos(x_{12} - \theta_0) \times (L_0 - \delta_1) + u_2 + \Delta f_2(x_2, u_2)] \]
\[ d_{1,1} = 0.1 \cos(2t), \quad d_{1,2} = 0.1 \sin(2t) \]
\[ d_{2,1} = 0.2 \sin(t), \quad d_{2,2} = 0.2 \cos(t) \]

with \( \Delta f_{1,2} = 0.3 \cos(x_{1,1} x_{1,2}) x_{2,1}, \Delta f_{1,2} = 0.2 \sin(x_{1,1} x_{1,2}) x_{2,2}, \Delta f_{2,1} = J_2^{-1}[(0.2 + 0.1 \cos(x_{1,1} x_{1,2})) \times u_1], \) and \( \Delta f_{2,2} = J_2^{-1}[(0.2 + 0.1 \cos(x_{1,1} x_{1,2})) \times u_2]. \)

The quantization level is set to \( \rho = 0.01. \) The design parameters are chosen as \( \xi = 18, \Gamma_0 = 100, \Gamma_2 = 10, \Gamma_3 = 10, \Gamma_4 = 2, \sigma_{W,i} = 0.1, \sigma_{i,1} = 0.5, \xi_{i,1} = 2, \sigma_{i,2} = 0.1, e = 0.25, \xi_{i,1} = 2, \xi_{i,2} = 0.707, \sigma_{i,1} = 60, \sigma_{i,2} = 80 \) where \( i = 1, 2. \) The control gains and weight tuning parameters of the existing adaptive tracker [11] are set to be identical to those of the proposed tracker.

The tracking results and errors for Example 2 are compared in Figs. 6 and 7. The tracking results of the position angles \( y_1 \) and \( y_2 \) are compared in Fig. 6. Fig. 7 shows a comparison of the tracking errors. Despite the quantization of state feedback signals, the proposed approach has a similar tracking performance to that of the previous adaptive tracker [11]. Fig. 8 illustrates the control inputs \( u_1 \) and \( u_2 \) of the proposed approach. The estimates of \( W_i \) and \( \delta_i, i = 1, 2, \) of the proposed approach are displayed in Fig. 9. From these results, we conclude that the proposed adaptive neural tracker using quantized state feedback is effective in coping with unknown nonaffine nonlinearities of MIMO pure-feedback systems and state quantization.

V. CONCLUSION

We have presented a neural-network-based adaptive quantized state feedback control design and stability analysis strategies for uncertain MIMO block-triangular pure-feedback nonlinear systems with state quantization. The key aspect of the proposed strategy is that adaptive neural compensation terms using quantized states are derived to ensure the boundedness of the quantization errors of the closed-loop signals and to deal with unknown control coefficient functions derived from recursive designs. The adaptive neural tracker and its adaptive laws have been designed via quantized states, and the quantization errors have been compensated by the adaptive laws. By constructing technical lemmas for quantization errors and adaptive parameters, the uniform ultimate boundedness of all signals of the closed-loop system using quantized feedback is proved based on the Lyapunov stability analysis. Finally, the simulation results demonstrate that the proposed theoretical strategy provides effective control with good tracking performance. The neural-network-based quantized feedback tracking problem in the presence of measurement noise or faults will be investigated in future studies.
