A GENERALIZATION OF SIMS CONJECTURE FOR FINITE PRIMITIVE GROUPS AND TWO POINT STABILIZERS IN PRIMITIVE GROUPS

PABLO SPIGA

Abstract. In this paper we propose a refinement of Sims conjecture concerning the cardinality of the point stabilizers in finite primitive groups and we make some progress towards this refinement.

In this process, when dealing with primitive groups of diagonal type, we construct a finite primitive group $G$ on a set $\Omega$ and two distinct points $\alpha, \beta \in \Omega$ with $G_{\alpha \beta} \leq G_\alpha$ and $G_{\alpha \beta} \neq 1$, where $G_\alpha$ is the stabilizer of $\alpha$ in $G$ and $G_{\alpha \beta}$ is the stabilizer of $\alpha$ and $\beta$ in $G$. In particular, this example gives an answer to a question raised independently by Peter Cameron in [3] and by Alexander Fomin in the Kourovka Notebook [14, Question 9.69].

1. Introduction

Let $G$ be a finite primitive group acting on a set $\Omega$ and let $\alpha \in \Omega$. The subdegrees of $G$ are the lengths of the orbits of the point stabilizer $G_\alpha := \{g \in G \mid \alpha^g = \alpha\}$ on $\Omega$.

Given a subdegree $d$ of $G$, there is no bound on the degree $|\Omega|$ of $G$, as a function of $d$ only. For example, for any prime $p$, the dihedral group of order $2p$ has a faithful primitive permutation representation of degree $p$ with subdegree $d = 2$. Despite this, if a finite primitive group $G$ has a small subdegree, then the structure of $G_\alpha$ is rather restricted, see for instance [15, 20, 23] and the much more recent results in [7, 12]. Following the investigations on the cases $d = 3$ and $d = 4$, Charles Sims [20] was lead to conjecture the following.

Theorem 1.1 (Sims conjecture). There is a function $f : \mathbb{N} \to \mathbb{N}$ such that, if $G$ is a finite primitive group with a suborbit of length $d > 1$, then the stabilizers have order at most $f(d)$.

This theorem was proved by Cameron, Praeger, Saxl and Seitz [5] using the O’Nan-Scott Theorem and the recently (at the time) announced classification of finite simple groups. The CFSGs spurred a new vitality in the old subject of finite permutation groups and this result was one of the first major applications of the CFSGs, see also [4].

In this paper we propose a strengthening of Sims conjecture that in our opinion captures the structure of point stabilizers of primitive groups to a finer degree. As well as Sims conjecture, our conjecture can be phrased in purely group-theoretic terminology. While as well as Sims conjecture, our conjecture can be phrased in purely group-theoretic terminology, but it is better understood borrowing some terminology from graph theory.

Let $G$ be a finite primitive group acting on a set $\Omega$ and let $\alpha$ and $\beta$ be two elements of $\Omega$. The orbital graph $\Gamma$ determined by the ordered pair $(\alpha, \beta)$, is the directed graph with vertex set $\Omega$ and with arc set $(\alpha, \beta)^G := \{(\alpha^g, \beta^g) \mid g \in G\}$. Clearly, $G$ is a group of automorphisms of $\Gamma$ acting primitively on its vertex set and $\Gamma$ is undirected if and only if the orbital $(\alpha, \beta)^G$ is self-paired, that is, $(\alpha, \beta)^G = (\beta, \alpha)^G$. We denote by $\Gamma^+(\gamma) := \{\delta \in \Omega \mid (\delta, \gamma) \in (\alpha, \beta)^G\}$ the out-neighborhood and by $\Gamma^-(\gamma) := \{\delta \in \Omega \mid (\gamma, \delta) \in (\alpha, \beta)^G\}$ the in-neighborhood, respectively, of the vertex $\gamma$ of $\Gamma$. As $\Omega$ is finite, it follows that the out-valency and the in-valency of $\Gamma$ are equal, that is, $|\Gamma^+(\gamma)| = |\Gamma^-(\gamma)|$ for every $\gamma \in \Omega$. Moreover, if we denote by $d$ this valency, then $d$ equals the cardinality of the suborbit $\beta^{G_\alpha} = \Gamma^+(\alpha)$. In particular, $d$ is a subdegree of $G$.

Given two vertices $\alpha$ and $\beta$ as above, we write $G_{\alpha \beta} := G_\alpha \cap G_\beta$. Moreover, we denote with

$$G^{+1}_\alpha := \bigcap_{\delta \in \Gamma^{+}(\alpha)} G_{\alpha \delta} \quad \text{and} \quad G^{-1}_\beta := \bigcap_{\delta \in \Gamma^{-}(\beta)} G_{\delta \beta},$$

the kernel of the action of $G_\alpha$ on $\Gamma^+(\alpha)$ and of $G_\beta$ on $\Gamma^-(\beta)$, respectively. Observe that the notation $G^{+1}_\alpha$ and $G^{-1}_\beta$ is slightly misleading because it does not show the dependency of this subgroup of $G$ from the graph $\Gamma$, however for not making the notation too cumbersome to use we prefer not to attach the label “$\Gamma$” in the notation for $G^{+1}_\alpha$ and $G^{-1}_\beta$.

Furthermore, we denote by $G^{+\alpha}_\alpha \cong G_\alpha/G^{1+}_\alpha$ and by $G^{-\beta}_\beta \cong G_\beta/G^{-1}_\beta$, the permutation group induced by $G_\beta$ on $\Gamma^+(\alpha)$ and on $\Gamma^-(\beta)$, respectively. The groups $G^{+\alpha}_\alpha$ and $G^{-\beta}_\beta$ are (not necessarily isomorphic) permutation groups of degree $d$ and they are sometimes refereed to as the local groups, see [16, 17] where this terminology is particularly suited.

Using the notation that we have established above, Sims conjecture claims that, when $d > 1$, the cardinality of $G_{\alpha \beta}$ is bounded above by a function of the valency $d$ of the orbital graph $\Gamma$. In other words, the order of the vertex stabilizer $G_{\alpha \beta}$

2000 Mathematics Subject Classification. Primary 20B25; Secondary 05E18.

Key words and phrases. arc-transitive graph, primitive group, Sims Conjecture, subdegree.
is bounded above by a function of the local group $G_{\alpha}^{\Gamma^+(\alpha)}$. (Actually, the order of the vertex stabilizer is bounded above simply by a function of the degree of the local group.) Broadly speaking, we wish to make a step further and we wonder whether, besides some families that can be explicitly classified, the order of the arc stabilizer $G_{\alpha\beta}$ is bounded above by a function of the order of the point stabilizer $G_{\alpha}^{\Gamma^+(\alpha)}$ of the local group $G_{\alpha}^{\Gamma^+(\alpha)}$. More precisely, we propose the following conjecture:

**Conjecture 1.2.** There exists a function $g : \mathbb{N} \to \mathbb{N}$ such that, if $G$ is a finite primitive group with a suborbit $\beta^{G_\alpha}$ of length $d > 1$, then either

(i): $G_{\alpha\beta}$ has order at most $g(|G_{\alpha\beta} : G_{\alpha}^{[1]}|)$, or

(ii): $G$ is in a well-described and well-determined list of exceptions.

It is quite unfortunate, that we cannot omit alternative (ii) in Conjecture 1.2. Examples in this direction are intricate to construct and we give an example later in this paper, see Example 2.2. A positive solution to Conjecture 1.2 can be seen as a strengthening of Sims conjecture, this is easy to see but we postpone the proof to Section 2.1. However, a positive answer to Conjecture 1.2 is a stronger result than Sims conjecture: we refer the reader to Example 2.2 to see this and to capture the idea behind our question. In this paper, we give some evidence towards the veracity of Conjecture 1.2.

A particularly interesting case for our conjecture is when $G_{\alpha\beta} \nsubseteq G_\alpha$. In this case, $G_{\alpha}^{[1]} = G_{\alpha\beta}$, that is, the local group $G_{\alpha}^{\Gamma^+(\alpha)}$ is regular. In this case, it was asked by Peter Cameron [5] whether $G_{\alpha\beta} = 1$, that is, whether the whole vertex stabilizer $G_{\alpha\beta}$ acts regularly on the out-neighborhood $\Gamma^+(\alpha)$. This question was also proposed by Fomin in the Kourovka Notebook [14, Question 9.69]. Remarkable evidence towards the veracity of the question of Cameron and Fomin is given by Konygin [8, 9, 10, 11]; however, to the best of our knowledge this question is still open. To some extent, Conjecture 1.2 can be seen as a generalization of the question of Cameron and Fomin, allowing $G_{\alpha\beta} \nsubseteq G_\alpha$, but relaxing the conclusion when $G_{\alpha\beta} \subseteq G_\alpha$. By investigating Conjecture 1.2 for primitive groups of diagonal type, we construct a finite primitive group with $G_{\alpha\beta} \subseteq G_\alpha$ and $G_{\alpha\beta} \neq 1$, thus giving an answer in the negative to the question of Cameron and Fomin. We present this example in Section 5.

## 2. Basic results

### 2.1. Relations between Sims conjecture and Conjecture 1.2

**Lemma 2.1.** Suppose that Conjecture 1.2 holds true. Then, any group satisfying part (i) of Conjecture 1.2 satisfies Sims conjecture.

**Proof.** Let $g$ be the function arising from a positive solution of Conjecture 1.2. We define a function $g' : \mathbb{N} \to \mathbb{N}$ by setting

$$g'(d) := \max \{|g(H_\delta)| : H \text{ transitive on } \{1, \ldots, d\}, \delta \in \{1, \ldots, d\}\}.$$

Now, let $G$ be a finite primitive group satisfying part (i) of Conjecture 1.2. Let $\beta^{G_\alpha}$ be a suborbit of $G$ of cardinality $d > 1$ and let $\Gamma$ be the corresponding orbital graph. Set $H := G_{\alpha\beta}^{\Gamma^+(\alpha)}$ and observe that $H$ is a transitive permutation group on $\Gamma^+(\alpha)$ of degree $d$. The stabiliser of a point in $H$ is $G_{\alpha\beta}^{\Gamma^+(\alpha)}$. Since $G$ satisfies Conjecture 1.2 (i), we have

$$|G_{\alpha\beta}| \leq g(|G_{\alpha\beta}^{\Gamma^+(\alpha)}|) \leq g'(d).$$

Now, $|G_\alpha| = |G_\alpha : G_{\alpha\beta}| |G_{\alpha\beta}| = d |G_{\alpha\beta}| \leq dg'(d)$. Therefore, Sims conjecture holds for $G$ by taking $f(d) := dg'(d)$. □

**Example 2.2.** It is interesting to consider finite primitive groups having a suborbit $\beta^{G_\alpha}$ of odd cardinality $d$ with $G_\alpha$ acting as a dihedral group on $\beta^{G_\alpha}$. In this case, $|G_\alpha : G_{\alpha\beta}| = d$ and $|G_{\alpha\beta} : G_{\alpha}^{[1]}| = 2$. It follows from the main result in [19] (and also from the work of Verret on $p$-subregular actions [21, 22]), that $|G_{\alpha\beta}|$ divides 16. In particular, $|G_{\alpha\beta}| \leq 16$. Observe that this upper bound on $|G_{\alpha\beta}|$ does not depend on $d$.

In particular, in this example, Sims conjecture requires bounding $|G_\alpha|$ as a function of $d$. However, Conjecture 1.2 is more demanding: since $|G_{\alpha\beta} : G_{\alpha}^{[1]}| = 2$ is a constant, Conjecture 1.2 demands either regarding $G$ is an exception or bounding $|G_{\alpha\beta}|$ from above with an absolute constant. Luckily, in this case, $G$ is not an exception, because from [21, 22], $|G_{\alpha\beta}| \leq 16$.

**Lemma 2.1** shows that, if Conjecture 1.2 holds true, then it might be possible proving Sims conjecture by checking (possibly with a direct case-by-case inspection) the groups falling in part (ii).

### 2.2. The O’Nan-Scott theorem and our investigation

The modern key for analyzing a finite primitive permutation group $G$ is to study the socle $N$ of $G$, that is, the subgroup generated by the minimal normal subgroups of $G$. The socle of an arbitrary finite group is isomorphic to the non-trivial direct product of simple groups; moreover, for finite primitive groups these simple groups are pairwise isomorphic. The O’Nan-Scott theorem describes in details the embedding of $N$ in $G$ and collects some useful information about the action of $N$. In [13, Theorem] five types of primitive groups are defined (depending on the group- and action-structure of the socle), namely HA (Affine), AS (Almost Simple), SD (Simple Diagonal), PA (Product Action) and TW (Twisted Wreath), and it is shown that every primitive group belongs to exactly
one of these types. We remark that in [18] this subdivision into types is refined, namely the PA type in [18] is partitioned
in four parts, which are called HS (Holomorphic simple), HC (Holomorphic compound), CD (Compound Diagonal) and
PA. For what follows, we find it convenient to use this subdivision into eight types of the finite primitive primitive groups.

In this paper we investigate Conjecture [2] using the O’Nan-Scott theorem.

3. Primitive groups of HA, TW, HS and HC type

Proposition 3.1. Let $G$ be a transitive group on $Ω$ containing a normal regular subgroup, let $Γ$ be a connected digraph
with vertex set $Ω$ and left invariant by the action of $G$. Then $G^+[1] = 1$, for every $α ∈ Ω$. In particular, Conjecture [2](i)
holds true when $G$ has O’Nan-Scott type HA, TW, HS and HC and the function $g$ can be taken so that $g(n) := 1$, for
every $n ∈ N$.

Proof. Let $α ∈ Ω$. Let $N$ be a regular normal subgroup of $G$ and let $H := G_α$. Then, $G$ is the semidirect product of $N$ by
$H$ (that is, $G = N G_α$, $N ∩ G_α = 1$ and $N = N × H$) and the action of $G$ on $Ω$ is permutation equivalent to the “affine”
action of $G$ on $N$, where $N$ acts on $N$ by right multiplication and where $H$ acts on $N$ by conjugation. In the rest of
the proof, we use this identification. In particular, under this equivalence, $α ∈ Ω$ corresponds to $1 ∈ N$. For each $β ∈ Γ^+(α)$, we
let $n_β$ be the element of $N$ corresponding to $β$, that is, $α^{n_β} = β$.

Then $G_α = C_H(n_β)$ and

\[
G^{+[1]}_α = \bigcap_{β ∈ Γ^+(α)} G_α β = \bigcup_{β ∈ Γ^+(α)} C_H(n_β) = C_H(⟨n_β | β ∈ Γ^+(α)⟩).
\]

Since $Γ$ is connected, we deduce $N = ⟨n_β | β ∈ Γ^+(α)⟩$. Hence $G^{+[1]}_α = C_H(N) = 1$. In other words, $G_α$ acts faithfully on
$Γ^+(α)$.

When $G$ has O’Nan-Scott type HA, TW, HS and HC, the proof follows by the fact that $G$ contains a normal regular
subgroup and by the fact that the non-trivial orbital graphs of $G$ are connected.

4. Primitive groups of SD type

We start by recalling the structure of the finite primitive groups of SD type. This will also allow us to set up the
notation for this section.

Let $ℓ ≥ 1$ and let $T$ be a non-abelian simple group. Consider the group $N = T^ℓ+1$ and $D = \{t_ℓ, t_ℓ \, t \in N | t \in T\}$, a
diagonal subgroup of $N$. Set $Ω := N/D$, the set of right cosets of $D$ in $N$. Then $|Ω| = |T|$. Moreover we may identify
each element $ω ∈ Ω$ with an element of $T$ as follows: the right coset $ω = D(α_0, α_1, . . . , α_ℓ)$ contains a unique element
whose first coordinate is $1$, namely, the element $(1, α_0^{-1} α_1, . . . , α_0^{-1} α_ℓ)$. We choose this distinguished coset representative.

Now the element $ϕ$ of Aut($T$) acts on $Ω$ by

\[
D(1, α_1, . . . , α_ℓ)^ϕ = D(1, α_1^ϕ, . . . , α_ℓ^ϕ).
\]

Note that this action is well-defined because $D$ is Aut($T$)-invariant. Next, the element $(t_0, . . . , t_ℓ)$ of $N$ acts on $Ω$ by

\[
D(1, α_1, . . . , α_ℓ)^{(t_0, . . . , t_ℓ)} = D(t_0 α_1 t_1, . . . , t_ℓ α_ℓ) = D(1, t_0^{-1} α_1 t_1, . . . , t_0^{-1} α_ℓ t_ℓ).
\]

Observe that the action induced by $(t_0, . . . , t_ℓ) ∈ N$ on $Ω$ is the same as the action induced by the inner automorphism
corresponding to the conjugation by $t$. Finally, the element $σ$ in Sym($\{0, . . . , ℓ\}$) acts on $Ω$ simply by permuting the
coordinates. Note that this action is well-defined because $D$ is Sym($ℓ + 1$)-invariant.

The set of all permutations we described generates a group $W$ isomorphic to

\[
T^ℓ+1 \cdot (\text{Out}(T) × \text{Sym}(ℓ+1)).
\]

A subgroup $G$ of $W$ containing the socle $N$ of $W$ is primitive if either $ℓ = 2$ or $G$ acts primitively by conjugation on the
$ℓ + 1$ simple direct factors of $N$, see [10, Theorem 4.5A]. The group $G$ is said to be primitive of SD type, when the second
case occurs, that is, $N ≤ G ≤ W$ and $G$ acts primitively by conjugation on the $ℓ + 1$ simple direct factors of $N$.

Write

\[
M = \{(t_0, t_1, . . . , t_ℓ) ∈ N | t_0 = 1\}.
\]

Clearly, $M$ is a normal subgroup of $N$ acting regularly on $Ω$. Since the stabilizer in $W$ of the point $D(1, . . . , 1)$ is
Sym($ℓ + 1$) × Aut($T$), we obtain

\[
W = (\text{Sym}(ℓ + 1) × \text{Aut}(T)) M.
\]

Moreover, every element $x ∈ W$ can be written uniquely as $x = σϕm$, with $σ ∈ \text{Sym}(ℓ + 1)$, $ϕ ∈ \text{Aut}(T)$ and $m ∈ M$.

Theorem 4.1. Let $G$ be a primitive group on $Ω$ of SD type, let $α$ and $β$ be two distinct elements from $Ω$ and consider the
action of $G$ on the orbital graph determined by $(α, β)$. Then one of the following holds

- $G^{+[1]}_α = 1$,
- $|G^{+[1]}_α| = ℓ + 1$, $G^{+[1]}_α ≤ \text{Sym}(ℓ + 1)$ and $G^{+[1]}_α$ acts regularly on $\{1, . . . , ℓ + 1\}$. Moreover, let $(t_0, t_1, . . . , t_ℓ) ∈ N$
with $t_0 = 1$ and $β = D(t_0 t_1, . . . , t_ℓ)$. The mapping $G^{+[1]}_α → T$ defined by $σ → t_0σ^{-1}$ is a group homomorphism.
Proof. We use the notation that we have established above. Without loss of generality we may assume that
\[ \alpha = D(1, 1, \ldots, 1). \]

Write
\[ \beta := D(1, t_1, \ldots, t_\ell), \]
for some \( t_1, \ldots, t_\ell \in T \). We set \( t_0 := 1 \), in particular, \( \beta = D(t_0, t_1, \ldots, t_\ell) \). This notation will make the last part of our proof easier to follow.

Let \( \varphi \in G_\alpha^+[1] \cap \text{Aut}(T) \). For each \( t \in T \), we let \( \iota_t \in \text{Aut}(T) \leq W_\alpha \) denote the permutation on \( \Omega \) induced by the conjugation via \( t \). Observe that \( t_\ell \in G \cap W_\alpha = G_\alpha \), for every \( t \in T \), because \( T^{\ell+1} = N \leq G \). As \( \varphi \in G_\alpha^+[1] \) and \( \iota_t \in G_\alpha \), we deduce that \( \varphi \) fixes \( \beta^{\iota_t} \), for every \( t \in T \). This means that
\[
D(1, t_1^{\iota_t}, \ldots, t_\ell^{\iota_t}) = \beta^{\iota_t} = \beta^{\varphi} = D(1, t_1^{\iota_t}, \ldots, t_\ell^{\iota_t}) = D(1, t_1^{\varphi}, \ldots, t_\ell^{\varphi}),
\]
for every \( t \in T \). Since \( \beta \neq \alpha \), there exists \( i \in \{1, \ldots, \ell\} \) with \( t_i \neq 1 \). Now, (1) gives \( t_i^{\iota_t} = t_i^{\varphi} \), for every \( t \in T \). Therefore
\[
\varphi \in \bigcap_{t \in T} C_{\text{Aut}(T)}(t_i^{\iota_t}) = C_{\text{Aut}(T)}((t_i^{\iota_t} \mid t \in T)) = C_{\text{Aut}(T)}(T) = 1.
\]
This shows that
\[
G_\alpha^+[1] \cap \text{Aut}(T) = 1.
\]

Now, \( G_\alpha^+[1] \) is a normal subgroup of \( G_\alpha \). Since \( G_\alpha \) acts primitively as a group of permutations on the \( \ell + 1 \) simple direct factors of \( T^{\ell+1} \), we obtain that either \( G_\alpha^+[1] \) projects trivially on Sym(\( \ell + 1 \)) or \( G_\alpha^+[1] \) projects to a transitive subgroup of Sym(\( \ell + 1 \)). If \( G_\alpha^+[1] \) projects trivially on Sym(\( \ell + 1 \)), then \( G_\alpha^+[1] \leq \text{Aut}(T) \) and hence \( G_\alpha^+[1] = 1 \) by (2). (In particular, in this case Conjecture 1.2 part (i) holds true). Therefore, for the rest of this proof we assume that
\[ G_\alpha^+[1] \]
projects to a transitive subgroup of Sym(\( \ell + 1 \)).

Observe now that \( \iota(T) = \{ t_i \mid t \in T \} \leq G_\alpha \) (because \( T^{\ell+1} = N \leq G \)) and that \( \iota(T) \trianglelefteq G_\alpha \) (because \( W_\alpha = \text{Aut}(T) \times \text{Sym}(\ell + 1) \)). We deduce that \( G_\alpha \) is a normal subgroup of \( G_\alpha \), and hence \( G_\alpha \trianglelefteq G_\alpha \). Since \( G_\alpha^+[1] \cap \text{Aut}(T) = 1 \), we deduce \( G_\alpha^+[1] \cap \iota(T) = 1 \). This is a transitive subgroup of Sym(\( \ell + 1 \)).

Next we show that \( G_\alpha^+[1] \) is a regular subgroup of Sym(\( \ell + 1 \)). Let \( H := N_G(T_0) \), where \( T_0 \) is the first simple direct factor of the socle \( N \). Now, \( H \) acts transitively on \( \Omega \), because \( N \leq H \), and \( H \) contains the normal regular subgroup \( M = T_1 \times \cdots \times T_\ell \). Therefore, by Proposition 3.1 applied to \( H \), we deduce \( H_\alpha^+[1] = 1 \). As \( |G : H| = |G : N_G(T_0)| = \ell + 1 \) and \( H_\alpha^+[1] = H \cap G_\alpha^+[1] \), we get \( |G_\alpha^+[1]| \leq \ell + 1 \). Since \( G_\alpha^+[1] \) is a transitive subgroup of Sym(\( \ell + 1 \)), \( G_\alpha^+[1] \) is a regular subgroup of Sym(\( \ell + 1 \)) and
\[
\ell + 1 = |G_\alpha^+[1]|.
\]

We need to recall in detail the action of Sym(\( \ell + 1 \)) on \( \Omega \). Given \( \sigma \in \text{Sym}(\ell + 1) \) and \( \omega = D(x_0, x_1, \ldots, x_\ell) \in \Omega \), we have
\[
\omega^\sigma = D(x_0^{\sigma^{-1}}, x_1^{\sigma^{-1}}, \ldots, x_\ell^{\sigma^{-1}}).
\]
The element \( \sigma \) in the right hand side of (3) appears as \( \sigma^{-1} \) to guarantee that this is a right action.

Recall \( \beta = D(1, t_1, \ldots, t_\ell) = D(t_0, t_1, \ldots, t_\ell) \). We now define a mapping
\[
w : G_\alpha^+[1] \longrightarrow T,
\]
\[
\sigma \longmapsto t_{\sigma^{-1}}.
\]
In other words, in the light of (3), \( w(\sigma) \) is the first coordinate of \( (t_0, t_1, \ldots, t_\ell)^\sigma = (t_0^{\sigma^{-1}}, t_1^{\sigma^{-1}}, \ldots, t_\ell^{\sigma^{-1}}) \).

Let \( \sigma, \tau \in G_\alpha^+[1] \). Since \( \tau \) fixes \( \beta \), we have
\[
\beta = \beta^\tau = D(t_0^{\tau}, t_1^{\tau}, \ldots, t_\ell^{\tau})
\]
and since \( \sigma \tau \) fixes \( \beta \), we have also
\[
\beta = \beta^{\sigma \tau} = D(t_0^{\sigma \tau}, t_1^{(\sigma \tau)^{-1}}, \ldots, t_\ell^{(\sigma \tau)^{-1}}).
\]
In other words, the two (\( \ell + 1 \))-tuples \( (t_0^{\sigma}, t_1^{\sigma}, \ldots, t_\ell^{\sigma}) \) and \( (t_0^{\sigma \tau}, t_1^{(\sigma \tau)^{-1}}, \ldots, t_\ell^{(\sigma \tau)^{-1}}) \) differ only by the left multiplication by an element of \( D \). Therefore, there exists \( t \in T \) such that
\[
(t t_0^{\sigma}, t t_1^{\sigma}, \ldots, t t_\ell^{\sigma}) = (t t_0^{\sigma \tau}, t t_1^{(\sigma \tau)^{-1}}, \ldots, t t_\ell^{(\sigma \tau)^{-1}}).
\]
By checking the first coordinates in (4), we obtain
\[
t t_0^{\sigma} = t t_0^{\sigma \tau}.
\]
Moreover, by comparing the coordinate appearing in position 0\textsuperscript{r} on the left-hand side and on the right-hand side of (2), we deduce \( tt_{(0r)^{-1}} = t_{(0r)^{-1}} \), that is, 
\[
t = tt_0 = t_{0r^{-1}}.
\]
Putting these two equations together, we obtain
\[
w(\sigma)w(\tau) = t_{0r^{-1}}t_{0r^{-1}} = t_{(0r)^{-1}} = t_{0(\sigma\tau)^{-1}} = w(\sigma\tau).
\]
This proves that our mapping \( w : G^+_{\alpha[1]} \to T \) is a group homomorphism. \( \square \)

The proof of Proposition 4.1 hints to the fact that in Conjecture 1.2 we do need the alternative (ii). We show that this is indeed the case in the next example.

**Example 4.2.** Let \( p \) be a prime number, let \( k \geq 7 \) be a positive integer and let \( r \) be a primitive prime divisor of \( p^k - 1 \), that is, \( r \) is relatively prime to \( p^i - 1 \) for each \( i \in \{1, \ldots, k - 1\} \). As \( k \geq 7 \), the existence of \( r \) is guaranteed by Zsigmondy’s theorem.

Let \( H := V \times C \) be the affine primitive group of degree \( p^k \), where \( V \) is an elementary abelian \( p \)-group of order \( p^k \) and where \( R \) is a cyclic group of order \( r \). (We use an additive notation for \( V \).) Let \( T \) be a non-abelian simple group containing a cyclic subgroup \( P \) of order \( p \) and with \( C_T(P) = P \) and let
\[
w : V \to P
\]
be an arbitrary surjective homomorphism.

We denote by \( T^V \) the set of all functions from \( V \) to \( T \). Observe that \( T^V \) is a group isomorphic to the Cartesian product of \( [V] = p^k \) copies of \( T \). We denote the elements of \( T^V \) as functions \( f : V \to T \).

We let \( G \) be primitive group of diagonal type
\[
T^V \rtimes H.
\]
Recall that the elements of \( \Omega \) are right cosets of \( D \) in \( T^V \), where \( D \) is the diagonal subgroup of \( T^V \), that is, \( D = \{ f \in T^V \mid f \) is constant \}. Let \( b = (t_v)_{v \in V} \in T^V \) where \( t_v = \omega(-v) \), for every \( v \in V \).

Let \( \alpha := D \), let \( \beta := Db \) and consider the orbital graph determined by \( (\alpha, \beta) \). Let \( v \in V \). Then
\[
b^v(x) = b(x - v) = w(-x + v) = w(-x)w(v) = w(v)w(-x) = w(v)b(x), \quad \forall x \in V.
\]
Thus \( b^v = w(v)b \) and hence \( \beta^v = Db^v = Db = \beta \). This shows \( V \leq G_{\alpha\beta} \). Since \( V \leq G_{\alpha} \), we deduce \( G_{\alpha[1]}^+ \leq V \). Now, from Proposition 4.1, we have \( G_{\alpha[1]}^+ = V \).

Thus \( G_{\alpha} = (T \times R)G_{\alpha[1]}^+ \) and
\[
G_{\alpha\beta} = (G_{\alpha\beta} \cap (T \times R))G_{\alpha[1]}^+.
\]
Let \( \varphi := th \in G_{\alpha\beta} \cap (T \times R) \), with \( t \in T \) and \( h \in R \). Observe that
\[
b^{th}(0) = b((0)^{h^{-1}})t = b(0)t = w(0)t = 1t = 1 = w(0) = b(0).
\]
Since \( Db = \beta = \beta^h = Db^h = Db \), from (3) we get \( b^h = b \).

For every \( v \in \text{Ker}(w) \leq V \), we have
\[
w(-v^{h^{-1}}) = (b(v^{h^{-1}}))t = b^{h}(v) = w(v) = 1.
\]
Therefore, \( w(v^{h^{-1}}) = 1 \). This gives \( \text{Ker}(w^{h^{-1}}) = \text{Ker}(w) \). As \( \dim \text{Ker}(w) = k - 1 \neq 0 \) and as \( R \) is a cyclic group of prime order acting irreducibly on the vector space \( V \), we deduce \( h = 1 \). This shows that \( \varphi = t \in T \).

Now, \( b^t = b \) if and only if \( t \) centralizes all the coordinates of \( b \). In other words, \( t \in C_T(P) = P \). Summing up,
\[
G_{\alpha\beta} = P \times V \) and \( G_{\alpha[1]}^+ = V.
\]
Thus \( |G_{\alpha\beta} : G_{\alpha[1]}^+| = |P| = p \) and \( |G_{\alpha[1]}^+| = p^k \). However, we cannot bound the cardinality of \( G_{\alpha[1]}^+ \) with \( p \) only.

**5. The example for the Cameron and Fomin question**

Our construction is quite elaborate and requires a number of ingredients:
- let \( A \) be a non-abelian simple group,
- let \( T \) be a non-abelian simple group containing a subgroup \( Q \) with \( Q = A \times A \) and with \( C_T(Q) = 1 \),
- let \( H \) be a group containing \( A \) with \( A \) maximal in \( H \), \( A \) core-free in \( H \) and, in the faithful permutation action of
\( H \) on the right cosets of \( A \), there exist two points whose setwise stabilizer is the identity.

We observe that there are groups \( A, T, Q \) and \( H \) satisfying the hypothesis above. For instance, we may take \( A := \text{Alt}(5) \), \( T := \text{Alt}(10) \), \( Q = \text{Alt}(5) \times \text{Alt}(5) \leq T \) and \( H := \text{PSL}_2(p) \) where \( p \) is a prime number with \( p \geq 61 \) and \( p \equiv 1 \) (mod 10).

Clearly, \( A \) and \( T \) are non-abelian simple and \( C_T(Q) = 1 \). Moreover, using the hypothesis on \( p \), \( A \) is a maximal subgroup in the Aschbacher class \( S \) of \( T \), see for instance [1] Table 8.2. Using the fact that \( p > 19 \), we see from [2] Table 1 that the base size of \( T \) in the action on the right cosets of \( A \) is 2. Actually, from the arguments in [2], it follows that whenever \( p \geq 61 \), there exist two points whose setwise stabilizer is the identity.
Let \( V := A^{[H:A]} \) and let \( L := V \rtimes H \) be a primitive group of TW type with regular socle \( V \) and with point stabilizer \( H \). The fact that \( L \) is primitive in its action on \( V \) follows from [6, Lemma 4.7A].

As in Example 4.2 we denote by \( TV \) the set of all functions from \( V \) to \( T \). We let \( G \) be primitive group of diagonal type \( T^V \rtimes L \).

The elements of \( \Omega \) are right cosets of \( D \) in \( T^V \), where \( D \) is the diagonal subgroup of \( T^V \), that is, \( D = \{ f \in T^V \mid f \) is constant\}. Relabelling the elements in the domain \( \{1, \ldots, |H : A|\} \), we may suppose that \( 1, 2 \) is a base for the action of \( H \) and the setwise stabilizer of \( \{1, 2\} \) in \( H \) is the identity. We define the group homomorphism

\[
w : V = A^{[H:A]} \longrightarrow Q \leq T,
\]

\[
(a_1, a_2, \ldots, a_{|H:A|}) \longrightarrow (a_1, a_2).
\]

Let \( b \in T^V \) with \( b(v) = \omega(v^{-1}) \), for every \( v \in V \). Let \( \alpha := D \), let \( \beta := Db \) and consider the orbital graph determined by \((\alpha, \beta)\). Let \( v \in V \). Then

\[
b^v(x) = b(xv^{-1}) = w((xv^{-1})^{-1}) = w(v^{-1}) = w(v)w(x^{-1}) = w(v)b(x), \quad \forall x \in V.
\]

Thus \( b^v = w(v)b \) and hence \( \beta^v = Db^v = Db = \beta \). This shows \( V \leq G_{\alpha\beta} \). Since \( V \leq G_{\alpha} \), we deduce \( G_{\alpha}^{[1]} \leq V \). Now, from Proposition 4.1 we have \( G_{\alpha}^{[1]} = V \).

Thus \( G_{\alpha} = T \times L = T \times HV = T \times H G_{\alpha}^{[1]} = (T \times H) G_{\alpha}^{[1]} \) and

\[
G_{\alpha\beta} = (G_{\alpha\beta} \cap (T \times H)) G_{\alpha}^{[1]}.
\]

Let \( \varphi := th \in G_{\alpha\beta} \cap (T \times H) \), with \( t \in T \) and \( h \in H \). Observe that

\[
b^{th}(1) = b(1^{h^{-1}})^t = b(1)^t = (1, 1)^t = (1, 1) = w(1) = b(1).
\]

Since \( Db = \beta = \beta^{th} = Db^{th} = Db \), from [7] we get \( b^{th} = b \).

For every \( v = (1, 1, a_3, \ldots, a_{|H:A|}) \in \text{Ker}(w) \leq A^{[H:A]} = V \), we have

\[
w((v^{-1})^{h^{-1}})^t = (b(v^{-1}))^t = b^{th}(v) = b(v) = w(v^{-1}) = (1, 1).
\]

Therefore, \( w((v^{-1})^{h^{-1}}) = (1, 1) \), for every \( v = (1, 1, a_3, \ldots, a_{|H:A|}) \in \text{Ker}(w) \leq A^{[H:A]} = V \). This gives that \( h \) fixes setwise \( \{1, 2\} \) and hence \( h = 1 \), by our assumption on the permutation action of \( H \) on the right cosets of \( A \). This shows that \( \varphi = t \in T \). Now, \( b^t = b \) if and only if, for every \( v = (a_1, a_2, \ldots, a_{|H:A|}) \in V \), we have \( b^t(v) = b(v) \), that is, \( (b(v))^t = b(v) \). This yields

\[
(a_1^{-1}, a_2^{-1})^t = (w(v^{-1}))^t = (b(v))^t = b(v) = w(v^{-1}) = (a_1^{-1}, a_2^{-1}).
\]

Since this holds for each \( (a_1, a_2) \in A \times A = Q \leq L \), we deduce \( t \in C_T(Q) = 1 \). This shows that \( \varphi = 1 \).

As \( \varphi \) was an arbitrary element in \( G_{\alpha\beta} \cap (T \times H) \), we get \( G_{\alpha\beta} \cap (T \times H) = 1 \) and hence \( G_{\alpha\beta} = G_{\alpha}^{[1]} \) from [8]. Therefore \( G_{\alpha\beta} \leq G_{\alpha} \).
