DIVISIBILITY OF BINOMIAL COEFFICIENTS AND GENERATION OF ALTERNATING GROUPS

JOHN SHARESHIAN AND RUSS WOODROOFE

ABSTRACT. We examine an elementary problem on prime divisibility of binomial coefficients. Our problem is motivated by several related questions on alternating groups.

1. INTRODUCTION

We will discuss several closely related problems. The first is an elementary problem concerning divisibility of binomial coefficients by primes. Consider the following condition that a positive integer \( n \) might satisfy:

1. There exist primes \( p \) and \( r \) such that if \( 1 \leq k \leq n - 1 \), then the binomial coefficient \( \binom{n}{k} \) is divisible by at least one of \( p \) or \( r \).

Question 1.1. Does Condition (1) hold for all positive integers \( n \)?

We were led to ask Question 1.1 by a problem on the alternating groups. Indeed, we consider several related group-theoretic conditions on a positive integer \( n \):

2. There exist primes \( p \) and \( r \) such that if \( H < A_n \) is a proper subgroup, then the index \( [A_n : H] \) is divisible by at least one of \( p \) or \( r \).

2' There exist primes \( p \) and \( r \) such that if \( P \) is a Sylow \( p \)-subgroup and \( R \) a Sylow \( r \)-subgroup of \( A_n \), then \( \langle P, R \rangle = A_n \).

3. There exist a prime \( p \) and a conjugacy class \( D \) in \( A_n \) consisting of elements of prime power order, such that if \( P \) is a Sylow \( p \)-subgroup of \( A_n \) and \( d \in D \), then \( \langle P, d \rangle = A_n \).

4. There exist conjugacy classes \( C \) and \( D \) in \( A_n \), both consisting of elements of prime power order, such that if \( (c, d) \in C \times D \), then \( \langle c, d \rangle = A_n \).

5. There exist conjugacy classes \( C \) and \( D \) in \( A_n \), both consisting of elements of prime order, such that if \( (c, d) \in C \times D \), then \( \langle c, d \rangle = A_n \).

If we wish to specify one or both of the primes, then we may say that \( n \) satisfies Condition (1) with \( p \), or that \( n \) satisfies Condition (1) with \( p \) and \( r \). We’ll use similar language for the other conditions.

The first author was supported in part by NSF Grants DMS-0902142 and DMS-1202337.
Conditions (2) and (2') are equivalent, and each condition in the above list implies the previous condition. That is, for any positive integer $n$ the following chain of implications holds, where the primes $p$ and $r$ may be held fixed.

\[(1.1) \quad (5) \implies (4) \implies (3) \implies (2') \iff (2) \implies (1)\]

See also Proposition 1.3 below.

All implications in (1.1) are completely trivial or immediate from the definition of a Sylow subgroup, with the exception of the implication (2) $\implies$ (1). This implication follows since $A_n$ has subgroups of index $\binom{n}{k}$ for each $0 \leq k \leq n$. (The stabilizer in $A_n$ of a $k$-subset of $[n]$ is such a subgroup.)

There are infinitely many positive integers $n$ that do not satisfy Condition (5). However, the set of such integers is rather sparse, and likely very sparse. See Proposition 1.6 and Theorem 1.5 below. We are not aware of any integer $n$ for which Conditions (1)–(4) fail to hold. In addition to Question 1.1 we will consider the following.

**Questions 1.2–1.4.** Do Conditions (2)–(4) hold for all positive integers $n$?

1.1. **Motivations and related questions.** Question 1.1 fits into a line of inquiry going back to [13] on the distribution of binomial coefficients that are divisible by a given prime. The remaining conditions and questions arose from our work and that of others on generation of finite simple groups. Recall that the Classification of Finite Simple Groups tells us that every simple group is isomorphic to one of the following: an alternating group $A_n$ with $n \geq 5$, a cyclic group of prime order, a group of Lie type, or one of twenty six sporadic groups. Conditions analogous to Conditions (2)–(5) are known or conjectured for sporadic and Lie type groups.

We ourselves became interested in these problems via Question 1.2. In [18], we define a group $G$ to be universally $(p, r)$-generated if $G = \langle P, R \rangle$ for any Sylow $p$-subgroup $P$ and Sylow $r$-subgroup $R$. (Compare with Condition (2')!) We say $G$ is universally $(2, *)$-generated if there is some prime $p$ such that $G$ is universally $(2, p)$-generated. We showed the following.

**Theorem 1.2** (Shareshian and Woodroofe [18]). If $G$ is a finite simple group that is abelian, of Lie type, or sporadic, then $G$ is universally $(2, *)$-generated.

We used Theorem 1.2 along with fixed-point theorems of Smith [19] and of Oliver [16], to show that the order complex of the coset poset of any finite group is non-contractible.

In light of Theorem 1.2 it is natural to ask whether $A_n$ is universally $(2, *)$-generated for every $n$—that is, whether every $n$ satisfies Condition (2) with 2. This is not the case. The first failure of universal $(2, *)$-generation is at $n = 7$. It may be easier to understand the second failure, at 15, since $n = 15$ does not
even satisfy Condition (1) with 2. Question 1.2 naturally suggests itself. We will further discuss the case \( p = 2 \) below in Section 1.3.

We found that similar conditions had been examined earlier. Dolfi, Guralnick, Herzog and Praeger first ask Question 1.4 in [5, Section 6]. These authors conjecture that the analogue of Condition (5) holds for all but finitely many simple groups of Lie type, but point out that the corresponding statement for alternating groups occasionally fails.

Condition (3) interpolates naturally between Conditions (2) and (4). Although they do not ask Question 1.3, Damian and Lucchini show in [2] that an analogue of Condition (3) holds for many sporadic simple groups and groups of Lie type. Indeed, they show that many simple groups are generated by a Sylow 2-subgroup \( P \) together with any element of a certain conjugacy class consisting of elements of prime order.

1.2. Results for arbitrary primes. Our first result adds an additional implication to the list in (1.1).

Theorem 1.3. Let \( p \) and \( r \) be primes. If the positive integer \( n \) is not a prime power, then Conditions (1) and (2) are equivalent for \( n \) with \( p \) and \( r \).

The case where \( n \) is a prime power is not difficult.

Proposition 1.4. If \( n \) is a power of the prime \( p \), then

(A) \( n \) satisfies Condition (3) with a Sylow 2-subgroup unless \( n = 7 \), and

(B) \( n \) satisfies Condition (4) with \( p \).

In particular, it follows from Theorem 1.3 and Proposition 1.4 that Questions 1.1 and 1.2 are equivalent. We remark that the requirement that \( n \neq 7 \) in Proposition 1.4 (A) is necessary, as \( n = 7 \) satisfies Condition (1), but not Condition (2), with the prime 2.

While Questions 1.1, 1.3 are still open, we have amassed a large collection of integers for which the answers are “yes”. The asymptotic density [15] of a set \( S \) of positive integers is defined to be

\[
\liminf_{M \to \infty} \frac{|S \cap [M]|}{M}.
\]

Dolfi, Guralnick, Herzog and Praeger remark in [5] that Condition (5) appears likely to hold with asymptotic density 1. We show the following.

Theorem 1.5. Let \( \alpha \) be the asymptotic density of the set of positive integers \( n \) that satisfy Condition (5), and let \( \rho \) denote the Dickman-de Bruijn function (see for example [9]). We have

(A) \( \alpha \geq 1 - \rho(20) > 1 - 10^{-28} \), and

(B) if either the Riemann hypothesis or the Cramér Conjecture holds, then \( \alpha = 1 \).
The authors also claim in [5] that Condition (5) fails for infinitely many values of \(n\), and that the smallest \(n\) for which Condition (5) fails is 210. We will see that the first claim is true, but the second is not.

**Proposition 1.6.** For any \(a \geq 3\), the integer \(n = 2^a\) fails to satisfy Condition (5).

Theorem 1.5 suggests a positive answer to Questions 1.1–1.4 for all but a vanishingly sparse set of large integers. We have also examined many small integers with the aid of a computer, verifying the following.

**Proposition 1.7.** Every \(n \leq 1,000,000,000\) satisfies Condition (2).

The key tool in the proofs of both Theorem 1.5 and Proposition 1.7 is the following sieve lemma.

**Lemma 1.8 (Sieve Lemma).** Let \(n \geq 9\) be an integer. Let \(p\) and \(r\) be primes, and let \(a\) and \(b\) be positive integers.

(A) If \(n\) is not a prime power, \(p^a\) divides \(n\), and \(r^b < n < r^b + p^a\), then \(n\) satisfies Condition (2) with \(p\) and \(r\).

(B) If \(p\) divides \(n\) and \(r + 2 < n < r + p\), then \(n\) satisfies Condition (5) with \(p\) and \(r\).

Theorem 1.5 follows from combining Lemma 1.8 with known results on prime gaps and smooth numbers. We also use Lemma 1.8 to do much of the work in verifying Proposition 1.7.

For those integers not handled by Lemma 1.8 (A), Theorem 1.3 tells us that it suffices to check divisibility of binomial coefficients. In particular, we can avoid making any computations in large alternating groups. We do not know how to avoid such computations for Condition (4). The slow speed of these computations is the main obstacle to a computational verification of Condition (4) for those values of \(n\) not addressed by Lemma 1.8.

1.3. **Results for \(p = 2\).** We return now to the case where one of the primes in Condition (2) is 2. Theorem 1.2 suggests this case as being particularly worthy of attention, and Proposition 1.4 gives infinitely many values of \(n\) for which Condition (2) holds with 2.

However, there are also infinitely many positive integers \(n\) that do not even satisfy Condition (1) with 2. By a theorem of Kummer (see Lemma 3.1 below), if \(n = 2^a - 1\) for some positive integer \(a\), then \(\binom{n}{k}\) is odd for all \(1 \leq k \leq n - 1\). By the same theorem, there is no prime dividing every nontrivial \(\binom{n}{k}\) unless \(n\) is a prime power. There are infinitely many \(n\) of the form \(2^a - 1\) that are not prime powers.

Using techniques similar to those for Proposition 1.7, we computationally verify the following.
**Proposition 1.9.** About 86.7% of the positive integers \( n \leq 1,000,000 \) satisfy Condition (2) with 2.

1.4. **Organization.** We begin in Section 2 by giving necessary background on maximal subgroups of alternating groups. In Section 3 we state the well-known theorem of Kummer on prime divisibility of binomial coefficients, and prove a analogue on prime divisibility of the number of equipartitions of a set. We use these results in Section 4 to prove Theorem 1.3, Propositions 1.4 and 1.6, and Lemma 1.8. We also verify that Condition (4) holds for all small alternating groups. We apply Lemma 1.8 to prove Theorem 1.5 in Section 5. We describe our computational verification of Propositions 1.7 and 1.9 in Section 6.

**Acknowledgements**

We thank Andrew Granville and Bob Guralnick for their thoughtful remarks. A comment by Ben Green led to a significant improvement in the bound given in Theorem 1.5 (A).

2. **Preliminaries**

In this section we discuss necessary background on alternating and symmetric groups. Readers familiar with basic facts about permutation groups can safely skip this section.

In order to show that the index of every subgroup of the alternating group \( A_n \) is divisible by either \( p \) or \( r \), it suffices to show the same for every maximal subgroup. The maximal subgroups of \( A_n \) are well-understood, as we now review. Additional background can be found in [4], see also [14].

We say that a subgroup \( H \leq A_n \) is transitive or primitive if the action of \( H \) on \( [n] \) satisfies the same property. That is, \( H \) is transitive if for every \( i, j \in [n] \), there is some \( \sigma \in H \) such that \( i \cdot \sigma = j \). A transitive subgroup \( H \) is imprimitive if there is a proper partition \( \pi \) of \( [n] \) into sets of size greater than one, such that the parts of \( \pi \) are permuted by the action of \( H \). If \( H \) is transitive and not imprimitive, then it is primitive. Clearly, every subgroup is either intransitive, imprimitive, or primitive. We examine maximal subgroups of \( A_n \) according to this trichotomy.

An intransitive subgroup \( H \) is maximal in the (sub)poset of intransitive subgroups of \( A_n \) if and only if \( H \) is the stabilizer in \( A_n \) of some nonempty proper subset \( X \subset [n] \). As \( A_n \) sits naturally in \( S_n \), it is illuminating to also consider the stabilizer \( H^+ \) in \( S_n \) of \( X \). Then \( H = H^+ \cap A_n \). It is clear that \( H^+ \cong S_{|X|} \times S_{n-|X|} \). If \( |X| = k \), then it follows either from this isomorphism or the Orbit-Stabilizer Theorem that

\[
[A_n : H] = [S_n : H^+] = \frac{n!}{k! \cdot (n-k)!} = \binom{n}{k}.
\]
Every imprimitive subgroup of $A_n$ stabilizes a partition of $[n]$. It follows easily that a subgroup $H$ is maximal in the (sub)poset of imprimitive subgroups of $A_n$ if and only if $H$ is the stabilizer of a partition of $[n]$ into $n/d$ parts of size $d$ for some nontrivial proper divisor $d$ of $n$. As in the intransitive case, we also consider the stabilizer $H^+$ of the same partition in the action by $S_n$. Then $H^+$ is isomorphic to the wreath product $S_d \wr S_{n/d}$. Since $H = H^+ \cap A_n$ (and $H^+ \not\leq A_n$), we see that

$$[A_n : H] = [S_n : H^+] = \frac{n!}{(d!)^{n/d} \cdot (n/d)!}.$$  

By either the Orbit-Stabilizer Theorem or an elementary counting argument, $[A_n : H]$ counts the number of partitions of $[n]$ into $n/d$ equal-sized parts.

The index of a primitive proper subgroup of $A_n$ is typically divisible by every prime smaller than $n$. See Theorem 4.1 and the discussion following for a precise statement.

3. **Kummer’s Theorem and an Analogue**

3.1. **Kummer’s Theorem.** We make considerable use of the following result of Kummer [13]. The most useful case of the lemma for us will be that where $a = 1$. See also [8] for an overview of related results.

**Lemma 3.1** (Kummer’s Theorem [13, pp115–116]). Let $k$ and $n$ be integers with $0 \leq k \leq n$. If $a$ is a positive integer, then $p^a$ divides $\binom{n}{k}$ if and only if at least $a$ carries are needed when adding $k$ and $n - k$ in base $p$.

3.2. **An Analogue for the Number of Equipartitions.** Lemma 3.1 completely describes the prime divisibility of indices of intransitive maximal subgroups of $A_n$. Lemma 3.2 below provides a weaker but similarly useful characterization regarding indices of imprimitive subgroups. Throughout this section, if $d$ is a nontrivial proper divisor of the positive integer $n$, then we will write $I_{n,d}$ for the number of equipartitions of $n$ into parts of size $d$. Thus,

$$I_{n,d} = \frac{n!}{(d!)^{n/d} \cdot (n/d)!}.$$  

**Lemma 3.2.** Let $n$ be a positive integer, $d$ be a nontrivial proper divisor of $n$, and $p$ be a prime. Then $p$ divides $I_{n,d}$ if and only if

1. at least one carry is necessary when adding $n/d$ copies of $d$ in base $p$,
   and
2. $d$ is not a power of $p$.  

Proof. It is straightforward to show by elementary arguments that

\[
I_{n,d} = \frac{1}{(n/d)!} \cdot \prod_{j=1}^{n/d} \binom{jd}{d} = \prod_{j=1}^{n/d} \frac{1}{j} \binom{jd}{d} = \prod_{j=1}^{n/d} \binom{jd - 1}{d - 1}.
\]

Our strategy is to use Lemma 3.1 to examine divisibility of the terms in these products.

Case 1. \(n/d < p\)

In this case \(p\) does not divide \((n/d)!\), and the first condition of the hypothesis implies the second. From (3.1) we thus see that \(p\) divides \(I_{n,d}\) if and only if \(p\) divides \(j(d)\) for some \(1 \leq j \leq n/d\). The claim for this case then follows from Lemma 3.1.

Case 2. \(n/d \geq p\)

In this case a carry is always necessary when adding \(n/d\) copies of \(d\), so we need only consider the second condition of the hypothesis.

If the base \(p\) expansion of \(d\) has at least 2 nonzero places, then there are at least 2 carries when adding \(d\) to \(pd - d\), as the base \(p\) expansion of \(pd\) is obtained by shifting that of \(d\) to the left by one place. It follows that \(p^2\) divides \(\binom{pd}{d}\), hence that \(p\) divides \(\binom{pd - 1}{d - 1} = \frac{1}{p} \binom{pd}{d}\). By (3.1), \(p\) divides \(I_{n,d}\).

Otherwise, we have \(d = kp^a\) for some \(1 \leq k < p\). Then the base \(p\) expansion of \((jd - 1) - (d - 1) = (j - 1)kp^a\) vanishes below the \(a\)th place. Also, the base \(p\) expansion of \(d - 1\) is \((k - 1)p^a + \sum_{i=0}^{a-1} (p - 1)p^i\). As the latter vanishes above the \(a\)th place, this place is the only possible location for a carry in adding \(d - 1\) and \(jd - 1\). If \(k = 1\), then the \(a\)th place of \(d - 1\) is 0, so no carry occurs and for no \(j\) does \(p\) divide \(\binom{j(d - 1)}{d - 1}\). If \(k > 1\), then a carry occurs at the \(a\)th place for values of \(j\) such that \((j - 1) \cdot k \equiv p - 1 \mod p\). (Such a \(j < n/d\) exists since \(\mathbb{Z}/p\mathbb{Z}\) is a field.)

\[\square\]

Corollary 3.3. Let \(n\) and \(b\) be positive integers and \(r\) be a prime, such that \(n/2 < r^b \leq n\). If \(d\) is a nontrivial proper divisor of \(n\) which is not a power of \(r\), then \(r\) divides \(I_{n,d}\).

Proof. Since \(r^b > n/2\), there is a 1 in the \(b\)th place of the base \(r\) expansion of \(n\). On the other hand, \(d \leq n/2\). Hence, the base \(r\) expansion of \(d\) has a 0 in the \(b\)th place. It follows that there is at least one carry when we sum \(n/d\) copies of \(d\). Lemma 3.2 then gives that \(r\) divides \(I_{n,d}\) unless \(d\) is a power of \(r\).

\[\square\]

One can indeed extract from (3.1) the highest power of \(p\) dividing \(I_{n,d}\), but we will not need to do so.
4. Proofs of the Sieve Lemma and other tools

In this section we prove several results that we will use as tools in the sections that follow, including Theorem 1.3, Lemma 1.8 and Propositions 1.4 and 1.6.

4.1. Proof of Theorem 1.3. Suppose \( n \) satisfies Condition (2) with \( p \) and \( r \). As described in Section 2, the maximal intransitive subgroups of \( A_n \) are stabilizers of \( k \)-subsets of \([n]\), and have index \( \binom{n}{k} \) in \( A_n \). Hence, \( n \) also satisfies Condition (1) with \( p \) and \( r \). See the discussion following (1.1).

Thus, in order to prove Theorem 1.3, it suffices to show that if \( n \) satisfies Condition (1) with \( p \) and \( r \), then the index of every primitive or imprimitive maximal subgroup is divisible by at least one of \( p \) or \( r \).

For the primitive case, we use the following version of a classic theorem of permutation group theory due to Jordan.

Theorem 4.1. (Jordan \[12\], see also \[4, Section 3.3\]) Let \( n \geq 9 \), and let \( H \) be a primitive subgroup of \( A_n \).

(1) If \( p \leq n - 3 \) is a prime, and \( H \) contains a \( p \)-cycle, then \( H = A_n \).

(2) If \( H \) contains the product of two transpositions, then \( H = A_n \).

The next lemma follows quickly.

Lemma 4.2. Let \( p \) be a prime. If \( n \geq 9 \) and \( p \leq n - 3 \), then \( p \) divides the index of every primitive proper subgroup of \( A_n \).

Proof. If \( p \) is odd, then every Sylow \( p \)-subgroup of \( A_n \) contains a \( p \)-cycle. Similarly, every Sylow 2-subgroup of \( A_n \) contains an element that is the product of two transpositions. In either case, Theorem 4.1 gives that no primitive proper subgroup of \( A_n \) contains any Sylow \( p \)-subgroup of \( A_n \). \( \square \)

Since Lemma 4.2 only applies when \( n \geq 9 \), we pause to handle the situation when \( n < 9 \). The only integer less than 9 that is not a prime power is 6, and the equivalence of Conditions (1) and (2) for \( n = 6 \) is obtained by direct inspection (see Table 1 below).

Now assume as above that \( n \geq 9 \) satisfies Condition (1) with \( p \) and \( r \). Since \( n \) is not a prime power, we see from Lemma 3.1 that \( p \) and \( r \) must be distinct, hence one must be smaller than \( n - 2 \). As \( n \geq 9 \), it follows from Lemma 4.2 that the index of every primitive proper subgroup is divisible by at least one of \( p \) or \( r \), as desired.

We now handle the imprimitive case, using Lemma 3.2. Let \( d \) be a divisor of \( n \). We notice that if \( p \) divides \( \binom{n}{d} \), then adding \( n - d \) and \( d \) in base \( p \) requires a carry (by Lemma 3.1). It follows immediately from Lemma 3.2 that the index of an imprimitive maximal subgroup is divisible by either \( p \) or \( r \), except possibly if \( d \) is a power of \( p \) or \( r \).
Suppose that $d$ is a power of $p$, and that $p^a$ is the highest power of $p$ dividing $n$. Then Lemma 3.1 shows that $\binom{n}{p}$ is not divisible by $p$, hence it is divisible by $r$. Adding $n/p^a$ copies of $p^a$ in base $r$ therefore requires a carry. Since $d \leq p^a$, adding $n/d$ copies of $d$ in base $r$ will also require a carry. Therefore, \( \frac{n!}{(d)!^{\lfloor n/d \rfloor} \cdot (n/d)!} \) is divisible by $r$, as desired. The case where $d$ is a power of $r$ is handled similarly.

4.2. Proof of Lemma 1.8 (A). Kummer’s Theorem (Lemma 3.1) gives us the following.

**Lemma 4.3.** Let $n$ be a positive integer, and let $p$ and $r$ be distinct primes. If there are positive integers $a$ and $b$ such that $p^a | n$ and $r^b < n < p^a + r^b$, then for $0 < k < n$ at least one of $p, r$ divides $\binom{n}{k}$.

**Proof.** Notice that since $p^a > n - r^b$, either $k < p^a$ or else $k > n - r^b$. We assume without loss of generality that $k \leq n/2$.

Let $k = \sum k_ip^i$ and $n = \sum n_ip^i$ respectively be the base $p$ expansions of $k$ and $n$. As $p^a | n$, therefore $n_i = 0$ for $i < a$. When $k < p^a$, then $k_j = 0$ for all $j \geq a$. Since $k \neq 0$, there is a carry when adding $k$ and $n - k$ in base $p$. It follows from Lemma 3.1 that $p | \binom{n}{k}$.

When $k > n - r^b$, we notice that $k \leq n/2 < r^b$, and therefore both $k$ and $n - k$ are between $n - r^b$ and $r^b$. In particular, the $b$th place of the base $r$ expansion of both $k$ and $n - k$ has a 0. Since $n/2 < r^b < n$, the $b$th place of the base $r$ expansion of $n$ has a 1. It follows that there is a carry when adding $k$ and $n - k$, hence by Lemma 3.1 that $r | \binom{n}{k}$. \( \square \)

Lemma 1.8 (A) follows from Lemma 4.3 and Theorem 1.3

4.3. Proof of Lemma 1.8 (B). Let $x \in A_n$ have cycle type $p^{n/p}$, that is, let $x$ be the product of $n/p$ pairwise disjoint $p$-cycles. (Since $p \neq 2$, a $p$-cycle is an even permutation.) Let $y \in A_n$ be an $r$-cycle. We take $C$ to be the conjugacy class containing $x$, and $D$ to be the conjugacy class containing $y$. Since we chose $(x, y)$ arbitrarily from $C \times D$, it is enough to show $(x, y) = A_n$, that is, that $(x, y)$ is not contained in a maximal subgroup of any of the three types discussed in Section 2.

Since $r < n - 2$, it is immediate from Theorem 4.1 that $(y)$ is contained in no maximal primitive subgroup.

If $p$ is a proper divisor of $n$, we see that $p \leq n/2$ and hence that $r > n - p \geq n/2$. It is then immediate by Corollary 3.3 that $(y)$ is contained in no imprimitive maximal subgroup. Otherwise, if $n = p$, then $A_n$ has no imprimitive maximal subgroups.

It remains to show that $(x, y)$ is transitive in the natural action on $[n]$. Since $y$ acts transitively on an $r$-set $Y \subseteq [n]$, it suffices to show that every $i \in [n]$
can be moved into $Y$ by $x$. But $i$ is permuted in a $p$-cycle by $x$, and since $r + p > n$, some element of this $p$-cycle must be in $Y$, as desired.

4.4. **Proof of Proposition 4.4.** Direct inspection verifies the proposition for $n \leq 8$. See Table 1 below. We assume henceforth that $n \geq 9$.

We first verify part (B). By the Bertrand-Chebyshev Theorem [15, Theorem 8.7] there is a prime $r$ with $n/2 < r < n - 2$. We let $x$ be any $r$-cycle, and notice that $\langle x \rangle$ is a Sylow $r$-subgroup. Then $r$ divides the index of any imprimitive or primitive maximal subgroup by Corollary 3.3 and Lemma 4.2 respectively.

We now take $y$ to be any $n$-cycle in the case where $n = p^a$ is odd, or the product of any two disjoint $2^{a-1}$-cycles in the case where $n = 2^a$ is even. In the former case, $\langle y \rangle$ is transitive. In the latter case, as $r > 2^{a-1}$, we see that $\langle x, y \rangle$ is transitive. In either case, $\langle x, y \rangle$ is contained in no intransitive maximal subgroup, hence $\langle x, y \rangle = A_n$. Since conjugation fixes cycle type, part (B) follows.

It remains to verify (A). In the case where $n$ is even, it follows from part (B). Otherwise, we take $y$ to be any $n$-cycle. Then $\langle y \rangle$ is transitive, while Lemmas 3.2 and 4.2 give that no imprimitive or primitive maximal subgroup contains a Sylow 2-subgroup. It follows that $\langle y, P \rangle = A_n$ for any Sylow 2-subgroup $P$, completing the proof of part (A).

4.5. **Proof of Proposition 4.6.** Let $C$ and $D$ be as in Condition 5. We will find $(c, d) \in C \times D$ such that $\langle c, d \rangle \neq A_n$.

Since $A_n$ is transitive, if $D$ does not consist of derangements then we may find an element $d$ of $D$ fixing $n$. The same holds for $C$. If $c$ and $d$ both fix $n$, then $\langle c, d \rangle$ is intransitive, hence a proper subgroup of $A_n$. This reduces us to the situation where one conjugacy class (without loss of generality $C$) consists of derangements.

Since $n = 2^a$, derangements of prime order in $A_n$ are fixed-point-free involutions. It is straightforward to verify that the fixed-point-free involutions of $A_n$ form a single conjugacy class. Thus, $C$ consists of all fixed-point-free involutions in $A_n$.

Since a Sylow 2-subgroup of $A_n$ intersects every conjugacy class of involutions nontrivially, we see that $D$ must consist of elements of odd prime order $p$. For any $d \in D$, every orbit of $\langle d \rangle$ is of size 1 or $p$. If $\langle d \rangle$ has more than two orbits, then let $O_1$ and $O_2$ be orbits. Now there is some $c \in C$ such that $O_1 \cup O_2$ is the union of the supports of 2-cycles in the disjoint cycle decomposition of $c$. The subgroup $\langle c, d \rangle$ is thus intransitive.

It remains only to consider the case where $\langle d \rangle$ has exactly two orbits. As $n = 2^a$, so $d$ is a $p$-cycle fixing exactly one point. Now $n = p + 1$, and so by the Sylow Theorems the subgroups of order $p$ in $A_n$ form a single conjugacy
Table 1. Indices of maximal subgroups and generating conjugacy class representatives for $A_n$, $5 \leq n \leq 8$. 

| $n$ | Maximal subgroup indices | Cond. (4) conj. class representatives |
|-----|--------------------------|--------------------------------------|
| 5   | 5, 6, 10                | $(1\ 2\ 3), (1\ 2\ 3\ 4\ 5)$      |
| 6   | 6, 10, 15               | $(1\ 2\ 3\ 4\ 5\ 6), (1\ 2\ 3\ 4\ 5)$ |
| 7   | 7, 15, 21, 35           | $(1\ 2\ 3\ 4\ 5), (1\ 2\ 3\ 4\ 5\ 6\ 7)$ |
| 8   | 8, 15, 28, 35, 56       | $(1\ 2\ 3\ 4\ 5\ 6\ 7\ 8), (1\ 2\ 3\ 4\ 5)$ |

4.5. **Very small alternating groups.** As Lemma 1.8 does not apply when $n \leq 8$, we examine small $n$ separately. The solvable alternating groups (where $n < 5$) all trivially satisfy Condition (5). For $5 \leq n \leq 8$, we present the indices of maximal subgroups of $A_n$, together with representatives for generating conjugacy classes as in Condition (4). This list is easy to produce either by GAP [6], or else by hand (using well-known facts about primitive groups of small degree).

For $n = 5$ or 7, these representatives are of prime order, so 5 and 7 satisfy Condition (4). Proposition 1.6 tells us that 8 fails Condition (5), and a similar argument or GAP computation shows that 6 also fails Condition (5).

5. **Asymptotic density**

In this section, we use Part (B) of Lemma 1.8 to prove Theorem 1.5. Lemma 1.8 tells us that $n$ satisfies Condition (5) unless both the largest prime divisor $p$ of $n$ and the largest prime $r$ that is less than $n - 2$ are small relative to $n$. This allows us to apply known and conjectured results about prime gaps, which we combine with known results about numbers without large prime divisors (“smooth numbers”).

We will use the following notation.

- We will denote the $k$th smallest prime number by $p_k$. For example, $p_1 = 2$ and $p_2 = 3$. 

• For a real number \( x > 2 \), we will denote by \( r(x) \) the largest prime that is no larger than \( x \).
• For positive real numbers \( x, y \), we will denote by \( \Psi(x, y) \) the number of positive integers no larger than \( x \) which have no prime factor larger than \( y \).

Our strategy is to show that if \( p \) is the largest prime divisor of \( n \), then asymptotically \( r(n) + p \) is frequently greater than \( n \). We remark that \( r(n) \geq n - 2 \) only on a set of asymptotic density 0, so we may treat the \( r + 2 < n \) condition of Lemma 1.8 (B) as reading \( r \leq n \) for the purpose of asymptotic density arguments.

We will require several tools from number theory, as we will describe below. See [9] for further background on (5.2) and (5.3), and [7] for background and history on (5.4) and (5.5).

5.1. Proof of Theorem 1.5 (A). Jia showed in [11] that, for any \( \epsilon > 0 \), there is a prime on the interval \([n, n + n^{1 - \epsilon/20}]\) for all \( n \) excluding a set of asymptotic density 0. It follows by routine manipulation that

\[
(5.1) \quad n - r(n) < n^{1/20} \quad \text{except on a set of asymptotic density 0.}
\]

See [10, Chapter 9] for further discussion of results of this type.

Dickman showed in [3] that

\[
(5.2) \quad \lim_{x \to \infty} \frac{\Psi(x, x^{1/u})}{x} = \rho(u) \quad \text{for any fixed } u,
\]

where \( \rho \) denotes the so-called Dickman-de Bruijn function, that is, the solution to the differential equation \( u \rho'(u) + \rho(u - 1) = 0 \).

By combining (5.1) and (5.2) with Lemma 1.8 (B), we see that the desired asymptotic density \( \alpha \) satisfies

\[
\alpha \geq 1 - \rho(20),
\]

as desired. Consulting the table of values for \( \rho \) in [9, Table 2], we see that \( \rho(20) \cong 2.462 \cdot 10^{-29} < 10^{-28} \).

5.2. Proof of Theorem 1.5 (B). Rankin showed in [17] that

\[
(5.3) \quad \lim_{x \to \infty} \frac{\Psi(x, \log^b x)}{x} = 0 \quad \text{for any } b > 1.
\]

Taking \( b = 3 \) in (5.3), we see that the set of integers \( n \) with no prime factor larger than \( \log^3 n \) has asymptotic density 0.

The Cramér Conjecture [11 (4)] says that there is a constant \( C \) such that

\[
(5.4) \quad p_{k+1} - p_k \leq C \log^2 p_k \quad \text{for all } k.
\]
In the same paper, Cramér [1, Theorem II] showed the Riemann Hypothesis to imply that

\[
\lim_{x \to \infty} \frac{1}{x} \cdot \sum_{p_k \leq x,\ \ p_{k+1} - p_k \geq \log^a p_k} (p_{k+1} - p_k) = 0.
\]

Thus, if either the Cramér Conjecture or the Riemann Hypothesis holds, then

\[
n - r(n) \leq \log^3 r(n) \leq \log^3 n
\]

except on a set of asymptotic density zero. Theorem 1.5 (B) follows upon combining (5.3) with \( b = 3 \), (5.6), and Lemma 1.8.

6. Computational results

In this section we describe the verification by computer of Proposition 1.7. Our program iterates through the integers, beginning with \( n = 9 \). We factor each integer into primes. If \( n \) is a prime power, then \( n \) satisfies Condition (3) and hence (2) by Proposition 1.4. In this case, we store \( n = r^b \) as the largest prime power known so far in the computation. Otherwise, we find the largest prime power \( p^a \) dividing \( n \). The program then checks whether \( p^a + r^b \) is greater than \( n \), where \( r^b \) is the largest prime power found so far. If so, then \( n \) satisfies Condition (2) with \( p \) and \( r \) by Lemma 1.8. This sieving method succeeds for all but 14,638 of the integers in the interval from 9 to 1,000,000,000. For these remaining integers, the program checks directly which indices of intransitive and imprimitive subgroups are divisible by \( p \) (using Lemmas 3.1 and 3.2), and searches for a prime \( r \) dividing those that are not. This second method works for all but 22 of the remaining 14,638 integers. For these 22 integers we perform a similar search, using divisors of \( n \) other than \( p \). See Table 2 for the results of this search.

Running this program out to \( n = 1,000,000,000 \) on a 2012 MacBook Pro with the GAP computer algebra system [6] takes around 2 weeks. This computation verifies Proposition 1.7.

We approach checking which values of \( n \) satisfy Condition (2) with the prime 2 in a similar fashion. When we apply Lemma 1.8 we look for a pair \( p^a + r^b > n > r^b \) (where \( p^a \mid n \)) as before, but now we require \( 2 \in \{ p, r \} \). This technique gives a positive answer for about 45.7% of the first 1,000,000 integers \( n \geq 9 \). The remaining values of \( n \) require significantly more computation, and as a result we did not examine values of \( n \) beyond 1,000,000.

Running the program to check Condition (2) with the prime 2 out to \( n = 1,000,000 \) takes around a day on a 2012 MacBook Pro. This computation verifies Proposition 1.9. More precisely, 867,247 of the integers between 9 and 1,000,000 satisfy Condition (2) with 2. The histogram in Figure 6.1 shows
| $n$                  | $p^n$ | Cond. (2) prime pairs |
|---------------------|-------|-----------------------|
| 31,416 = $3^3 \cdot 7 \cdot 11 \cdot 17$ | 17$^1$ | (2, 7853) |
| 46,800 = $2^4 \cdot 3^2 \cdot 5^2 \cdot 13$ | 5$^2$ | (2, 149) |
| 195,624 = $3^3 \cdot 7 \cdot 11 \cdot 13 \cdot 19$ | 19$^1$ | (2, 3) |
| 5,504,490 = $2 \cdot 3^3 \cdot 5 \cdot 19 \cdot 29 \cdot 37$ | 37$^1$ | (2, 276251) |
| 7,458,780 = $2^2 \cdot 3 \cdot 5 \cdot 7^2 \cdot 43 \cdot 59$ | 59$^1$ | (2, 5) |
| 9,968,112 = $2^4 \cdot 3^2 \cdot 7 \cdot 11 \cdot 29 \cdot 31$ | 31$^1$ | (2, 3) |
| 12,387,600 = $2^4 \cdot 3^3 \cdot 5^2 \cdot 31 \cdot 37$ | 37$^1$ | (2, 3) |
| 105,666,600 = $2^3 \cdot 3 \cdot 5^2 \cdot 13 \cdot 19 \cdot 23 \cdot 31$ | 31$^1$ | (2, 5) |
| 115,690,848 = $2^5 \cdot 3 \cdot 7 \cdot 13 \cdot 17 \cdot 19 \cdot 41$ | 41$^1$ | (2, 3) |
| 130,559,352 = $2^3 \cdot 3 \cdot 7 \cdot 11 \cdot 31 \cdot 43 \cdot 53$ | 53$^1$ | (2, 3) |
| 146,187,444 = $2^2 \cdot 3 \cdot 13 \cdot 19 \cdot 31 \cdot 37 \cdot 43$ | 43$^1$ | (2, 31) |
| 225,613,050 = $2 \cdot 3 \cdot 5^2 \cdot 13 \cdot 37 \cdot 53 \cdot 59$ | 59$^1$ | (2, 3) |
| 275,172,996 = $2^2 \cdot 3 \cdot 7 \cdot 29 \cdot 37 \cdot 43 \cdot 71$ | 71$^1$ | (2, 3) |
| 282,429,840 = $2^4 \cdot 3 \cdot 5 \cdot 7 \cdot 11 \cdot 17 \cdot 29 \cdot 31$ | 31$^1$ | (2, 29) |
| 300,688,752 = $2^4 \cdot 3 \cdot 7 \cdot 13 \cdot 23 \cdot 41 \cdot 73$ | 73$^1$ | (2, 11) |
| 539,509,620 = $2^2 \cdot 3 \cdot 5 \cdot 13 \cdot 17 \cdot 23 \cdot 29 \cdot 61$ | 61$^1$ | (2, 1201) |
| 653,426,796 = $2^2 \cdot 3 \cdot 11 \cdot 19 \cdot 43 \cdot 73 \cdot 83$ | 83$^1$ | (2, 3) |
| 696,595,536 = $2^4 \cdot 3^2 \cdot 7 \cdot 13 \cdot 17 \cdot 53 \cdot 59$ | 59$^1$ | (2, 3) |
| 784,474,592 = $2^5 \cdot 11 \cdot 29 \cdot 31 \cdot 37 \cdot 67$ | 67$^1$ | (2, 29) |
| 798,772,578 = $2 \cdot 3 \cdot 19 \cdot 29 \cdot 41 \cdot 71 \cdot 83$ | 83$^1$ | (2, 563) |
| 815,224,800 = $2^5 \cdot 3 \cdot 5^2 \cdot 13 \cdot 17 \cdot 29 \cdot 53$ | 53$^1$ | (2, 87013) |
| 851,716,320 = $2^5 \cdot 3 \cdot 5 \cdot 7 \cdot 13 \cdot 17 \cdot 31 \cdot 37$ | 37$^1$ | (2, 31) |

Table 2. The values of $n \leq 1,000,000,000$ together with their maximal prime power divisors $p^n$, such that $n$ does not satisfy Condition (2) with $p$. Each such $n$ satisfies Condition (2) with either 2 or 3.

the density of those $n$ which do not satisfy Condition (2) with 2. We remark that this histogram appears to show that the failing values are concentrated towards the values of $n$ slightly preceding integers that are divisible by a high power of 2.

Source code and output for all computer programs discussed in this section is available through the arXiv as ancillary files. They are also currently available from the second author’s web page. A list of the values of $n \leq 1,000,000$ such that $n$ does not satisfy Condition (2) with the prime 2 can be found in the same places.
Figure 6.1. A histogram showing the density of integers that do not meet Condition (2) with the prime 2.
