Solvatochromic Dyes as Empirical Indicators of Solvent Polarity

Christian Reichardt*

As every chemist knows, solvents can have a strong influence on reaction rates, on the position of chemical equilibria, and on the position of spectral absorption bands [1]. E.g., the S1 solvolysis of 2-chloro-2-methylpropane is ca. 1011 times faster in water than in the less polar solvent benzene. Chemists have usually attempted to understand solvent effects in terms of the polarity of the solvent. But what does solvent polarity mean? The simplicity of idealized electrostatic solvation models has led to the use of the relative permittivity (εr) and of the permanent dipole moment (μ) – or functions thereof – as solvent polarity parameters. This approach often failed because the intermolecular forces between solute and solvent molecules are much more complicated: in addition to the nonspecific coulombic, directional, inductive, and dispersion interactions, there exist also specific interactions such as hydrogen bonding, electron-pair donor (EPD)/electron-pair acceptor (EPA), and solvophobic interactions. Hence, from a more practical point of view, it seems to be more favourable to include in the term ‘solvent polarity’ the overall solvation capability for i) educts and products (→ chemical equilibria), ii) reactants and activated complexes (→ reaction rates), and iii) molecules in the ground and excited state (→ light absorption), which in turn depends on the action of all possible, nonspecific and specific, intermolecular interactions between solute and solvent molecules – excluding such interactions leading to definite chemical alterations of the solute molecules [2].

Obviously, solvent polarity such defined cannot be described quantitatively by means of single physical parameters such as permittivity or dipole moment. Other indices of solvent polarity are sought. Therefore, empirical parameters of solvent polarity have been introduced [1]. A common approach is to assume that some particular equilibrium, reaction rate, or spectral absorption is a suitable model for other solvent-dependent processes. If one carefully selects an appropriate, sufficiently solvent-sensitive reference process, an empirical measure of solvent polarity can be derived from it, which is believed to provide a more comprehensive measure of the overall solvation capability of the solvents than do their individual physical data.

The first suggestion that solvatochromic dyes should be used as indicators of solvent polarity was made by Brookler et al. in 1951 [3], but Kosower in 1958 [4] was the first to set up an empirical solvent scale, using the intermolecular charge-transfer absorption of negatively solvatochromic 1-ethyl-4-methoxycarbonylpyridinium iodide as a reference process. Kosower’s Z-scale, although widely used, has some practical limitations. Therefore, in 1963, another solvent polarity scale, the so-called Et(30)-scale, has been introduced [5–7]. The negatively solvatochromic pyridinium N-phenoxide betaine dye 1 (see the Scheme) exhibits one of the largest solvatochromic effects ever observed: its long-wavelength intramolecular charge-transfer (CT) absorption band is shifted by 9730 cm⁻¹ (357 nm) on going from water (λ = 453 nm) to diphenyl ether (λ = 810 nm). Solutions of 1 are red-coloured in methanol, violet in ethanol, blue in isoamyl alcohol, green in acetone, and yellow in anisole, thus comprising the whole visible region and allowing even a visual estimation of the solvent polarity.

In order to avoid the dimension kcal/mol, the use of normalized ET(30)-values has been recommended recently [6]. They are defined according to Eqn. 1, using water and tetramethylsilane (TMS) as extreme reference solvents.

\[
\frac{\text{ET(solute)} - \text{ET(TMS)}}{\text{ET(water)} - \text{ET(TMS)}} = 30.7
\]

\[
\text{ET(water)} - \text{ET(TMS)} = 32.4
\]

Hence, the ET(30)-scale ranges from 0.0 for TMS, the least polar solvent, to 1.0 for water, the most polar solvent.

Since betaine 1 is only sparingly soluble in water and insoluble in aliphatic hydrocarbons, the more lipophilic penta(tert-butyl)-substituted dye 2 [6] as well as the more hydrophilic methanesulfonyl-substituted dye 3 [9] have been used as secondary standard betaine dyes. That way, at present ET(30)-values are known for more than 300 organic solvents and numerous binary solvent mixtures [1,7].
In addition to its negative solvatochromism, pyridinium N-phenoxide betaine dyes such as 1 exhibit also the phenomenon of thermo-solvatochromism, piezo-solvatochromism, and halochromism [1]. That is, the position of the long-wavelength CT-absorption band of dissolved 1 depends on the solution temperature [13], on external pressure [14], and on the addition of salts (electrolytes; ionophores) [9][15]. Attempts at the discovery of so-called chiro-solvatochromism by means of the chiral (S,S)-configured betaine dye 5, dissolved in pairs of homochiral, enantiomeric solvents have failed so far [16].

Surprisingly, the pyridinium N-thiophenoxide betaine dye 4 exhibits practically the same sensitivity to HBD (protic) solvents as 1, in spite of the fact that sulfur is known to act as worse H-bond acceptor than oxygen [10].

The empirical solvent polarity parameter $E_T(30)$ has found manifold applications some of which are compiled in the Figure. The application of the $E_T(30)$-values to chemical reactivity [11] and analytical chemistry [12] has been reviewed.

A decrease in the temperature of solutions of 1 leads to a hypsochromic shift of its CT-absorption band. This new kind of thermochromism, called thermo-solvatochromism, is obviously caused by increased solvent-mediated stabilization of the dipolar ground state of 1 relative to its less dipolar excited state. In other words, the lower the temperature, the higher the $E_T(30)$-value of the solvent, and the higher its solvation capability. That is, solvent polarity is temperature-dependent [13].

With increasing external pressure (up to 10 kbar), again a hypsochromic shift in the solution spectra of 1 is observed [14]. This
piezo-solvatochromism obviously results from the pressure-supported differential solvation of the dipolar ground state of I. The higher the external pressure, the higher the $E_T(30)$-value of the solvent, and the higher its solvation capability. That is, solvent polarity is pressure-dependent. This pressure-dependence of the solvation capability of organic solvents should not be neglected in modern high-pressure chemistry!

The addition of salts to solutions of I in organic solvents causes hypsochromic shifts of its solvatochromic CT-absorption band. E.g., the addition of KI, NaI, LiI, BaI$_2$, Ca(SCN)$_2$, and Mg(ClO$_4$)$_2$ to solutions of I in acetonitrile leads to a differential hypsochromic band shift with this ionophore order, i.e. with increasing charge density of the cation [15]. The hypsochromic shifts are concentration-dependent, they increase with increasing salt concentration. Obviously, loose ion-pair formation between the phenoxide oxygen atom and the metal cation increases the ionization energy of the electron-donor moiety of I, whereas the electron-acceptor part of I remains unchanged. As result, the intramolecular CT-absorption band of I is hypsochromically shifted.

Are aqueous electrolyte solutions more polar than pure water? Addition of salts (up to 1M salt) to aqueous solutions of the more water-soluble betaine dye 3 leads in all cases to hypsochromic band shifts which correspond to an increase of the $E_T(30)$-values by ca. 1-4 kcal/mol. Thus, aqueous salt solutions are indeed more polar than water [9]. Unfortunately, $E_T(30)$-values for higher concentrated aqueous salt solutions (> 1M) are not available because the betaine dye 3 is salted out.

The salt-dependent solution spectra of I and 3 constitute a new type of genuine halochromism, in contrast to the trivial halochromism first found by Baeyer and Villiger [17]. Examples of this trivial halochromism are acid/base reactions in solution in which a colourless educt forms a coloured product during a chemical reaction, e.g. (CaH$_3$)$\text{C}_{\text{OH}}$ (colourless) $+\text{H}_2\text{O} \rightarrow (\text{CaH}_2\text{)}\text{C}^+ +2\text{H}_2\text{O}$. The genuine halochromism of I and 3, however, is produced without any chemical alteration of the halochromic dyes! We have recently proposed to speak of negative (positive) genuine halochromism then only when the UV/VIS-absorption band of a dissolved compound is hypsochromically (bathochromically) shifted on addition of an added electrolyte, and when this band shift is not accompanied by a chemical alteration of the chromophore [9][18].

A particular cation-selective genuine halochromism has been observed in solutions of the new crown-ether-substituted betaine dyes 6 [18]. E.g., addition of $10^{-2}$ M potassium iodide to a $10^{-3}$ M solution of 6 ($n = 1$) in acetonitrile gives rise to a colour change from violet ($\lambda = 583$ nm) to dark-red ($\lambda = 529$ nm; $\Delta \lambda = 54$ nm). Again, an ion-pair formation between alkali metal cation and phenoxide part, supported by the crown-ether ring, is responsible for this rather large halochromic shift of the intramolecular CT band of 6. Since this negative halochromism depends on the radius of the cation of the added salt as well as on the size of the crown-ether ring, the new betaine dyes 6 represent a new class of cation-selective chromoionophores possibly useful as cation indicators.

I thank all my coworkers listed in the references. This work was supported by the Deutsche Forschungsgemeinschaft, Bonn, and the Fonds der Chemischen Industrie, Frankfurt (Main).

Synopsis

Nomenclature and terminology of graphite intercalation compounds

Covalent graphite compounds, i.e. graphite fluoride and graphite oxide, should be distinguished from graphite intercalation compounds in which layers of the intercalated substance are inserted between planar carbon sheets of the graphite structure with concomitant charge transfer. Particular to graphite intercalation compounds is their tendency to form periodically stacked high-stage compounds in which only a fraction of the interlayer spaces of the graphite host lattice is filled with intercalated layers. The stage number is defined by the ratio of the total number of interlayer spaces to the number of filled interlayer spaces.

Synopsis

Nomenclature and terminology of graphite intercalation
compounds

Covalent graphite compounds, i.e. graphite fluoride and graphite oxide,
should be distinguished from graphite intercalation compounds in which
layers of the intercalated substance are inserted between planar
sheets of the graphite structure with concomitant charge
transfer. Particular to graphite intercalation compounds is their tendency
to form periodically stacked high-stage compounds in which only a
fraction of the interlayer spaces of the graphite host lattice is filled with
intercalated layers. The stage number is defined by the ratio of the total
number of interlayer spaces to the number of filled interlayer spaces.
Donor and acceptor compounds are differentiated by the direction of the electron transfer to or from the carbon layers, respectively. In naming a graphite intercalation compound, the intercalated element or compound precedes the word graphite, whilst the electropositive constituent is written first in the formula. The stage number is added in parentheses to the name or formula. Often, the space between intercalated ions is filled with solvent molecules; in this case the name or formula of the solvent compound is inserted after that of the electropositive constituent, otherwise it is added after that of the intercalated species. Graphite intercalation compounds are non-stoichiometric; this fact should be taken into account in their formulation. Binary (ternary, etc.) intercalation compounds contain one (two, etc.) chemical species in addition to graphite; free acids and their anions are taken as one chemical species.

In bi-intercalation compounds two different chemical species are inserted in separate interlayer spaces. Rules for structural notation follow those used in the description of polypeptides of metal dichalcogenides. Suggestions are presented for the symbols to be used for interlayer spacings, thicknesses of intercalated layers, etc.

Comments on the document are welcome and should be sent by 31 August 1992 to: Dr. H.P. Boehm, Institute for Anorganic Chemistry der Universität, Meierstrasse 1, D-München 2.

Nomenclature for chromatography

The Commission on Analytical Nomenclature of IUPAC has been active for a long time in establishing nomenclatures for chromatography. After proposing suitable nomenclatures for gas chromatography and ion exchange the Commission developed a unified nomenclature for chromatography.

Parallel to these activities other standardization bodies and scientists have also dealt with nomenclatures on gas chromatography, liquid chromatography, exclusion chromatography, and planar chromatography.

The original activities of the IUPAC Commission on Analytical Nomenclature aimed to create a unified nomenclature applicable to all forms of chromatography took place over 10 years ago. Since that time the chromatography techniques advanced significantly. Based on this development it was decided to prepare a new, up-to-date universal chromatography nomenclature, which also considers the recommendations incorporated in the various other nomenclatures developed since the original work of IUPAC.

The present nomenclature was prepared for the Commission by Dr. L.S. Ettre. It considers all the previous nomenclatures referenced above as well as the three publications dealing with these nomenclatures.

The present nomenclature deals with all chromatographic terms and definitions used in the major chromatographic techniques such as gas, liquid, and supercritical-fluid chromatography, column and planar chromatography, partition, adsorption, ion-exchange and exclusion chromatography. However, it does not include terms related to the results calculated from chromatography data such as e.g. the various molecular weight terms computed from the primary data obtained by exclusion chromatography.

Comments on the document are welcome and should be sent by 30 June 1992 to: Prof. C.A. Cramers, Eindhoven University of Technologv, Lab. Instrumental Analysis, Dept. of Chemistry, NL-5600 MB Eindhoven, The Netherlands.

European Federation for Medicinal Chemistry

Announcement

The European Federation for Medicinal Chemistry (EFMC) announces the W.T. Nauta Award for Pharma-cochemistry. The prize will honour the memory of Prof. Dr. Wijbe Nauta, whose activities have been very important for the advancement of medicinal chemistry in general and for the development of international organization structures for this discipline. The W.T. Nauta Award will acknowledge results of research in the field of medicinal chemistry obtained by a scientist from one of the countries of the EFMC sphere or research that has been carried out in one of these countries; the Award may also be used to acknowledge any other activities which have contributed to the advancement of medicinal chemistry and/or to the cooperation between countries in this field.

Comments on the document are welcome and should be sent by 30 June 1992 to: Prof. C.A. Cramers, Eindhoven University of Technology, Lab. Instrumental Analysis, Dept. of Chemistry, NL-5600 MB Eindhoven, The Netherlands.

Ehrungen

Die Gesellschaft Deutscher Chemiker verlieh in ihrer Festungssitzung anlässlich der 23. GDCh-Hauptversammlung in München am 9. September 1991 Herrn Professor Dr. Wolfgang Oppusser, Département de Chimie Organique, Université de Genève, die Otto-Wallach-Plakette in Anerkennung seiner Pionierleistungen auf dem Gebiet innovativer Synthesemethoden.
Donor and acceptor compounds are differentiated by the direction of the electron transfer to or from the carbon layers, respectively. In naming a graphitic intercalation compound, the intercalated element or compound precedes the word graphite, whilst the electropositive constituent is written first in the formula. The stage number is added in parentheses to the name or formula. Often, the space between intercalated ions is filled with solvent molecules; in this case the name or formula of the solvent compound is inserted after that of the electropositive constituent, otherwise it is added after that of the intercalated species. Graphite intercalation compounds are non-stoichiometric; this fact should be taken into account in their formulation. Binary (ternary, etc.) intercalation compounds contain one (two, etc.) chemical species in addition to graphite; free acids and their anions are taken as one chemical species.

In bi-intercalation compounds two different chemical species are inserted in separate interlayer spaces. Rules for structural notation follow those used in the description of polyanions of metal dichalcogenides. Suggestions are presented for the symbols to be used for interlayer spacings, thicknesses of intercalated layers, etc.

Comments on the document are welcome and should be sent by 31 August 1992 to: Dr. H.P. Boehm, Institute für Anorganische Chemie der Universität, Meiersstraße 1, D–München 2.

The present nomenclature was prepared for the Commission by Dr. L.S. Ettre. It considers all the previous nomenclatures referenced above as well as the three publications dealing with these nomenclatures.

The present nomenclature deals with all chromatographic terms and definitions used in the major chromatographic techniques such as gas, liquid, and supercritical-fluid chromatography, column and planar chromatography, partition, adsorption, ion-exchange and exclusion chromatography. However, it does not include terms related to the results calculated from chromatography data such as e.g. the various molecular weight terms computed from the primary data obtained by exclusion chromatography.

The European Federation for Medicinal Chemistry (EFMC) announces the W.T. Nauta Award for Pharmacochemistry.

The prize will honour the memory of Prof. Dr. Wijbe Nauta, whose activities have been very important for the advancement of medicinal chemistry in general and for the development of international organization structures for this discipline.

The W.T. Nauta Award will acknowledge results of research in the field of medicinal chemistry obtained by a scientist from one of the countries of the EFMC sphere or research that has been carried out in one of these countries; the Award may also be used to acknowledge any other activities which have contributed to the advancement of medicinal chemistry and/or to the cooperation between countries in this field.

The scientist whose work and/or activities complies with the description given above may qualify for the Award.

The Award will be given for the first time in 1992 and subsequently every second year. The selection of the recipient is the responsibility of the Management Committee of the EFMC which will nominate a special jury for this purpose. The recipient will receive a diploma and Dfl. 15,000.

Nominations for the Award are expected no later than March 1, 1992, at the Secretariat of the W.T. Nauta Award, c/o Prof. Dr. R.F. Rekker, Department of Pharmacochemistry, Vrije Universiteit, De Boelelaan 1083, NL–1081 HV Amsterdam, The Netherlands; tel.: 020–548 57 26; fax: 020–546 14 79. The proposals should include a short curriculum vitae with a list of publications and indicate the reasons for which the candidate qualifies for the Award.
Donor and acceptor compounds are differentiated by the direction of the electron transfer to or from the carbon layers, respectively. In naming a graphite intercalation compound, the intercalated element or compound precedes the word graphite, whilst the electronegative constituent is written first in the formula. The stage number is added in parentheses to the name or formula. Often, the space between intercalated ions is filled with solvent molecules; in this case the name or formula of the solvent compound is inserted after that of the electronegative constituent, otherwise it is added after that of the intercalated species. Graphite intercalation compounds are non-stoichiometric; this fact should be taken into account in their formulation. Binary (ternary, etc.) intercalation compounds contain one (two, etc.) chemical species in addition to graphite; free acids and their anions are taken as one chemical species.

In bi-intercalation compounds two different chemical species are inserted in separate interlayer spaces. Rules for structural notation follow those used in the description of polytypes of metal dichalcogenides. Suggestions are presented for the symbols to be used for interlayer spacings, thicknesses of intercalated layers, etc.

Comments on the document are welcome and should be sent by 31 August 1992 to: Dr. H.P. Boehm, Institute für Anorganische Chemie der Universität, Meierstrasse 1, D-München 2.

Nomenclature for chromatography

The Commission on Analytical Nomenclature of IUPAC has been active for a long time in establishing nomenclatures for chromatography. After proposing suitable nomenclatures for gas chromatography and ion exchange the Commission developed a unified nomenclature for chromatography.

Parallel to these activities other standardization bodies and scientists have also dealt with nomenclatures on gas chromatography, liquid chromatography, exclusion chromatography, and planar chromatography.

The original activities of the IUPAC Commission on Analytical Nomenclature aimed to create a unified nomenclature applicable to all forms of chromatography took place over 10 years ago. Since that time the chromatography techniques advanced significantly. Based on this development it was decided to prepare a new, up-to-date universal chromatography nomenclature, which also considers the recommendations incorporated in the various other nomenclatures developed since the original work of IUPAC.

The present nomenclature was prepared for the Commission by Dr. L.S. Ettre. It considers all the previous nomenclatures referenced above as well as the three publications dealing with these nomenclatures.

The present nomenclature deals with all chromatographic terms and definitions used in the major chromatographic techniques such as gas, liquid, and supercritical-fluid chromatography, column and planar chromatography, partition, adsorption, ion-exchange and exclusion chromatography. However, it does not include terms related to the results calculated from chromatography data such as e.g. the various molecular weight terms computed from the primary data obtained by exclusion chromatography.

Comments on the document are welcome and should be sent by 30 June 1992 to: Prof. C.A. Crumers, Eindhoven University of Technology, Lab. Instrumental Analysis, Dept. of Chemistry, NL-5600 MB Eindhoven, The Netherlands.

European Federation for Medicinal Chemistry

Announcement

The European Federation for Medicinal Chemistry (EFMC) announces the W.Th. Nauta Award for Pharma-chemistry.

The prize will honour the memory of Prof. Dr. Wijbe Nauta, whose activities have been very important for the advancement of medicinal chemistry in general and for the development of international organization structures for this discipline.

The W.Th. Nauta Award will acknowledge results of research in the field of medicinal chemistry obtained by a scientist from one of the countries of the EFMC sphere or research that has been carried out in one of these countries; the Award may also be used to acknowledge any other activities which have contributed to the advancement of medicinal chemistry and/or to the cooperation between countries in this field.

Comments on the document are welcome and should be sent by 30 June 1992 to: Prof. C.A. Crumers, Eindhoven University of Technology, Lab. Instrumental Analysis, Dept. of Chemistry, NL-5600 MB Eindhoven, The Netherlands.

In the field of medicinal chemistry (Gewässerschutz, Lärmschutz, Lufthygiene etc.) and projects (Umweltverträglichkeitsprüfungen, betrieblichen Umweltschutz, Abfall, «Ökobilanzen», etc.) are engaged, the NDS-U is mainly an environmental laboratory.

The new Award will be given for the first time in 1992 and every year thereafter. The selection of the recipient is the responsibility of the Management Committee of the EFMC which will nominate a special jury for this purpose. The recipient will receive a diploma and DM 15,000.

Nominations for the Award are expected no later than March 1, 1992, at the Secretariat of the W.Th. Nauta Award, c/o Prof. Dr. R.F. Rekker, Department of Pharmacocchemistry, Vrije Universiteit, De Boelelaan 1083, NL-1081 HV Amsterdam, The Netherlands; tel.: 020-548 57 26; fax: 020-548 14 79. The proposals should include a short curriculum vitae with a list of publications and indicate the reasons for which the candidate qualifies for the Award.

Ehrenungen

Die Gesellschaft Deutscher Chemiker verlieh in ihrer Festsession anlässlich der 23. GDCh-Hauptversammlung in München am 9. September 1991 Herrn Professor Dr. Wolfgang Oppolzer, Département de Chimie Organique, Université de Genève, die Otto-Wallach-Plakette in Anerkennung seiner Pionierleistungen auf dem Gebiet innovativer Synthesemethoden.
Donor and acceptor compounds are differentiated by the direction of the electron transfer to or from the carbon layers, respectively. In naming a graphene intercalation compound, the intercalated element or compound precedes the word graphite, whilst the electropositive constituent is written first in the formula. The stage number is added in parentheses to the name or formula. Often, the space between the intercalated ions is filled with solvent molecules; in this case the name or formula of the solvent compound is inserted after that of the electropositive constituent, otherwise it is added after that of the intercalated species. Graphite intercalation compounds are non-stoichiometric; this fact should be taken into account in their formulation. Binary (ternary, etc.) intercalation compounds contain one (two, etc.) chemical species in addition to graphite; free acids and their anions are taken as one chemical species.

In bi-intercalation compounds two different chemical species are inserted in separate interlayer spaces. The European Federation for Medicinal Chemistry (EFMC) announces the W.T. Naata Award for Pharmacochemistry.

The prize will honour the memory of Prof. Dr. Wijbe Naata, whose activities have been very important for the advancement of medicinal chemistry in general and for the development of international organization structures for this discipline.

The W.T. Naata Award will acknowledge results of research in the field of medicinal chemistry obtained by a scientist from one of the countries of the EFMC sphere or research that has been carried out in one of these countries; the Award may also be used to acknowledge any other activities which have contributed to the advancement of medicinal chemistry and/or to the cooperation between countries in this field.

The scientist whose work and/or activities complies with the description given above may qualify for the Award.

The Award will be given for the first time in 1992 and subsequently every second year. The selection of the recipient is the responsibility of the Management Committee of the EFMC which will nominate a special jury for this purpose. The recipient will receive a diploma and Drf. 15,000.

Nominations for the Award are expected no later than March 1, 1992, at the Secretariat of the W.T. Naata Award, c/o Prof. Dr. R.F. Rekker, Department of Pharmacochemistry, Vrije Universiteit, De Boelelaan 1083, NL-1081 HV Amsterdam, The Netherlands; tel.: 020-548 57 26; fax: 020-546 14 79. The proposals should include a short curriculum vitae with a list of publications and indicate the reasons for which the candidate qualifies for the Award.

Ingeneurschule beider Basel (HTL)

Nachdiplomstudium Umweltschutz an der Ingeneurschule beider Basel

Ab Herbst 1992 wird an der Inge-
nieurschule beider Basel, Muttenz, neu ein Nachdiplomstudium Um-
weit (NDS-U) angeboten. Für den Aufbau des NDS-U wurden vom
Technikurisrat Dr. Heinz Leuen-
berger, Solothurn, und Dr. Thomas
Hein, Olten, als hauptamtliche
Dozenten mit je 50% Pausam ge-
wählt.

Das neue Ausbildungszen-
trum wendet sich an Ingenieuri-
nen und Naturwissenschaft/-innen, die in Ämtern, Industriebetrieben und In-
geneieurunternehmen Umwelt-
fragen bearbeiten. Absolvent/-i-
nen des NDS-U sollen fähig sein
- umweltbezogene Anforderun-
gen bereits bei der Planung, Projek-
tierung und Produktion zu be-
rücksichtigen (Prävention)
- bestehende Umweltprobleme zu
erkennen, zu bewerten und die
richtigen Massnahmen interdis-
ziplinär zu veranlassen (Interven-
tion).

Die Gesellschaft Deutscher Chemiker
verleih in ihrer Festszieh
anlässlich der 23. GDCh-Hauptversammlung
in München am 9. September 1991

Herrn Professor Dr.
Wolfgang Oppenier,
Département de Chimie Organique,
Université de Genèv,
die Otto-Wallach-Preishez

in Anerkennung seiner Pionierleistungen auf dem Gebiet innovativer
Synthesenmethoden.
