Trends in total hospital financial performance under the prospective payment system

by Charles R. Fisher

In this article, the author examines trends in determinants of total hospital facility revenues, expenses, and net profits during the period 1977-89. Measures of change in transaction prices are developed, which enable an analysis of trends in real hospital outputs and total factor productivity. The main source of hospital spending growth in excess of the gross national product is identified as growth in hospital employee compensation.

Introduction

In order to focus on the overall performance of hospitals under the prospective payment system (PPS), I chose to study those hospitals that were under PPS since the inception of that program in October 1983. Thus, data for hospitals in States that had their own cost-control programs during some portion of the PPS period (Maryland, Massachusetts, New Jersey, and New York) are excluded from the study because their specific payment systems could confound the numbers.

Two basic data sources are used for this analysis:
• American Hospital Association (AHA) annual surveys for 1977 through 1989 as reported in the annual publication Hospital Statistics (American Hospital Association, 1977-89).
• Medicare Cost Reports for report years 1985-89. Data and analysis based on Medicare Cost Reports are shown in the Technical note.

This article first examines the “average” hospital’s financial performance and total hospital activity in the context of the general economy, using AHA data for report years 1977-89. The study period was divided into four periods:
• From 1977 through 1979, the effective period of the industry’s Voluntary Effort (VE) cost-containment program.
• From 1979 through 1983, the pre-PPS period when VE was no longer effective.
• From 1983 through 1985, the initial period of PPS.
• From 1986 through 1989, the later period of PPS.

Each of the four periods displays unique aspects of trends in hospital expenditures.

Key determinants of financial performance are examined:
• A measure of hospital output transaction prices that enables an estimate of hospital real output trends.
• Expense trends as a function of outputs, total factor productivity rates, and input resource prices.
• Net profit and net revenue trends.
• Trends in nominal and real expenditures and in transaction prices for the hospital industry compared with nominal and real output and prices in the general economy.

The same trend analysis is then applied to Medicare Cost Reports for report years 1985-89.

Key findings of this article are:
• Hospital spending grew less than economywide spending (gross national product, or GNP) in the initial PSS period but resumed historical excess growth in the later PPS period.
• Rising hospital input prices, particularly hospital worker compensation increases in excess of general economy compensation changes, are a primary source for hospital spending rates in excess of general economy spending.
• Hospital inpatient outputs, which declined in the initial PPS period, resumed historical growth patterns in the later PPS period.
• Rapid growth in outpatient outputs characterized the entire PPS period.
• Hospital net profit rates, although declining in the recent PPS period following unprecedented high rates in the initial PPS period, were higher at the end of the study period than at the beginning of the study period.

Trends in revenues and profits

From 1977 through 1989, the average PPS hospital’s net revenues quadrupled, reaching nearly $32 million by 1989 (Table 1). Most of these revenues, about 93 percent, were derived from revenues provided by patients or their third-party payers (government or private health insurers) for patient care goods and services provided by the hospital. The remainder represents revenues received by hospitals from sources other than patient care, for example, investments and proceeds from parking lots, gift shops, etc.

During the period 1977-89, the average hospital’s net profits fluctuated from a low of $258,000 in 1977 to a high of $1.6 million in 1985, the last full year of PPS implementation. Overall, from 1977 through 1989, the average hospital’s net profits increased fivefold, ending with nearly $1.3 million in profits in 1989.

Net profits as a percent of net revenues increased 25 percent during the period, rising from 3.2 percent in 1977 to more than 6 percent in the initial PPS period.
Table 1
Per hospital gross patient revenues, net patient and non-patient revenues, expenses, and net profits: Fiscal years 1977-89

| Fiscal year | Gross patient revenues | Net revenues | Number of hospitals | Number of hospitals |
|-------------|------------------------|--------------|--------------------|--------------------|
|             | Total                  | Inpatient    | Outpatient         | Total              | Non-patient | Expenses | Net profits | Net revenues | 1989 $44,301 $34,901 $9,400 | $31,972 $29,896 $2,177 $30,704 $1,298 4.0 4,968 |
| 1989        | 38,077                 | 30,375       | 7,702              | 28,896             | 26,761       | 2,105    | 27,732      | 1,134        | 3.9 5,043 |
| 1988        | 32,935                 | 26,706       | 6,229              | 26,026             | 24,178       | 1,848    | 24,793      | 1,233        | 4.7 5,104 |
| 1987        | 29,102                 | 24,012       | 5,090              | 24,053             | 22,175       | 1,878    | 22,545      | 1,508        | 6.3 5,166 |
| 1986        | 25,286                 | 22,116       | 4,170              | 22,322             | 20,693       | 1,429    | 20,864      | 1,269        | 7.3 5,210 |
| 1985        | 24,990                 | 21,519       | 3,470              | 21,773             | 19,455       | 1,274    | 19,282      | 1,274        | 6.1 5,232 |
| 1984        | 23,193                 | 20,243       | 2,950              | 19,431             | 18,075       | 1,256    | 18,805      | 1,250        | 5.0 5,250 |

and subsequently stabilizing at about 4 percent in the late 1980s. During the same time, the number of community hospitals declined steadily from 5,308 to 4,968.

Net revenues and expenses, while decelerating rapidly in the initial period of PPS following rapid growth in pre-PPS periods, began to accelerate again in the later PPS period (Table 1). Net revenues, which had been increasing at double-digit rates prior to PPS, dropped to single-digit increases from 1984 through 1987, but subsequently resumed double-digit growth in 1988.

Outputs and output prices

Hospital outputs are defined here as any good or service appearing on a hospital bill in the form of a billable charge. Specific outputs do not have to be detailed but must be measurable by being included in an aggregate charge. I define a charge for an output as the output "list price" and the cash value of an output as the output "transaction price." The output transaction price represents the list price after discounts are applied.

Two output transaction prices are estimated: a patient care transaction output price, which represents

Health Care Financing Review/Spring 1992/Volune 13, Number 3
net patient revenues divided by patient care outputs, and a total output transaction price, which represents total net revenues divided by patient care outputs. (Total net revenues are the sum of net patient revenues and non-patient revenues derived from sources other than patient care.)

The method to derive patient care output transaction prices is described in the “Data sources and limitations” section of this article. The results of the method are shown in Table 2.

Patient care transaction prices increased at double-digit rates in the pre-PPS period and at near double-digit rates in the initial PPS period (Table 2). After 1983, however, third-party insurers, particularly Medicare, sharply limited increases in the transaction prices they were willing to pay hospitals. In this later PPS period, transaction price increases decelerated. Starting in 1988, however, patient care transaction price changes, although well below pre-PPS period rates, began once again to accelerate.

Changes in patient care real outputs are derived by dividing changes in net patient revenues by changes in patient care transaction prices. Patient care real outputs per hospital, which had been increasing substantially in the immediate pre-PPS period over the prior VE period, decreased nearly 2 percent annually in the initial 2 years of PPS (Table 2). Beginning in 1986, however, real outputs per hospital sharply accelerated and continued to increase at rapid rates thereafter. By 1989, real outputs were increasing at about the same rate as the average annual pre-PPS rate, about 4.6 percent annually (Table 2).

I converted rates of change in real outputs per hospital in Table 2 into constant dollar levels in Table 3, where fiscal year (FY) 1987 was arbitrarily chosen as a base year for the constant-dollar values. I distributed

the total hospital constant-dollar values to the inpatient facility and outpatient facility sectors by dividing inpatient gross revenues and outpatient gross revenues, respectively, by the total Consumer Price Index (CPI) hospital component and by the total CPI hospital component less the CPI hospital room component. This procedure is equivalent to the derivation of transaction prices shown in the “Data sources and limitations” section of this article, because a change in gross patient revenues deflated by a change in list prices provides a measure of growth in total real outputs. Because gross patient revenues for inpatient care represent the product of real inpatient outputs and list prices for real inpatient outputs, gross inpatient revenues deflated by list prices for real inpatient outputs provide a measure of inpatient real outputs. Real outpatient facility outputs were derived similarly.

I found that real outputs of outpatient facilities declined rapidly in the initial period of PPS (about 3 percent annually in 1984 and 1985), as real outputs of outpatient facilities increased sharply (at double-digit rates after 1984). This was particularly true in 1985, when new Medicare payment policies were implemented that encouraged outpatient surgery as an alternative to inpatient surgery (Table 3).

As inpatient admission rates and average lengths of stay began to stabilize, after declining rapidly in the initial PPS period (Table 4), inpatient real outputs resumed their historical rates of increase in the later PPS period (Table 5). Outputs per hospital day, which had been accelerating continuously since a low point observed in 1979 (the effective period of the VE program), decelerated in 1984, when PPS was introduced. Subsequently, outputs per patient day appeared to accelerate through 1986 and then tended to rise more slowly thereafter (Table 5).

### Table 2: Trends in patient care hospital output prices and outputs: Fiscal years 1977-89

| Fiscal Year | CPI for hospitals (list price proxy) | Ratio of gross to net patient revenues | Percent change in output transaction price | Patient care net revenue per hospital | Patient care real output per hospital |
|-------------|-------------------------------------|---------------------------------------|-------------------------------------------|--------------------------------------|--------------------------------------|
| 1989        | 156.1                               | 1.462                                 | 4.9                                       | 6.1                                  | 11.0                                 |
| 1988        | 140.3                               | 1.423                                 | 4.5                                       | 3.8                                  | 10.7                                 |
| 1987        | 132.9                               | 1.362                                 | 4.7                                       | 2.1                                  | 8.0                                  |

| Period | Average annual percent change |
|--------|-------------------------------|
| 1977-89 | 3.7                          |
| 1988-89 | 3.7                          |
| 1989-93 | 3.7                          |
| 1990-95 | 3.7                          |
| 1996-97 | 3.7                          |

1987 base year.
2Real output equals nominal output divided by the Consumer Price Index (CPI) for hospitals.

NOTE: Data for Maryland, Massachusetts, New Jersey, and New York were excluded.

SOURCES: CPI data from (U.S. Department of Labor, Bureau of Labor Statistics, 1977-89); hospital revenue data from (American Hospital Association, 1977-89).

Total output transaction prices, as contrasted with patient care output transaction prices, are defined as total net revenues divided by patient care outputs. Total output transaction prices recognize that hospitals receive revenues from sources other than patients or their third-party payers. Total output transaction price changes are derived by dividing changes in total net revenues by changes in patient care real outputs. Total output transaction prices (Table 6) generally change at the same rate as patient care output transaction prices (Table 2) because the proportion of total net revenues represented by non-patient revenues remains relatively constant, and it is a small proportion.

In every year except 1985, total hospital output transaction prices rose more slowly than the CPI hospital component (Table 6 and Figure 1). In the early period of the study, total output transaction prices rose at slightly less than the CPI hospital component (list prices). In the initial 2 years of PPS, 1984 and 1985, combined output transaction price changes increased as a proportion of the CPI for hospital changes, actually exceeding the CPI list price increases in 1985, only to resume a relatively slower rate in later years of PPS. Part of these trends appears to be related to the rapid increase in Medicare PPS net revenues per Medicare real output in the first 2 years of PPS, followed by sharp constraints on Medicare PPS net revenues per Medicare real outputs in the following years.

**Expenses**

Hospital expenses can be defined as the product of three factors: the number of real outputs produced, the inverse of total factor productivity rates (where total factor productivity consists of labor productivity, capital productivity, and other factor productivity), and the average price of input resources. These relationships are represented in the identity:

\[
\text{Expenses} = \frac{(\text{Outputs})}{(\text{Inputs/Outputs})} \times (\frac{(\text{Expenses/Inputs})}{(\text{Expenses/Inputs})})
\]

Because changes in expenses, real outputs, and unit prices per resource input (sometimes called an input price index or market basket, adjusted for skill-mix changes) have been estimated, the identity implies a measure of total factor productivity change for the hospital sector (or more precisely, a measure of the inverse of total factor productivity). This is because total factor productivity is defined as real outputs divided by real inputs.

In this study, I used an input price market basket prepared by the Health Care Financing Administration for the Bureau of Economic Analysis, U.S. Department of Commerce, altered to reflect employee compensation (wages per full-time equivalent [FTE] employee and employee benefits per FTE obtained from AHA) specific to the subset of hospitals that were included in this study. Hospital employee labor compensation per FTE generally rose faster than private non-agricultural employee compensation throughout the period (Table 7 and Figure 2). The hospital input price (or market basket) incorporating these employee compensation changes is shown in Table 8. The market basket implicitly incorporates any skill-mix changes that may be occurring in the hospital industry because the compensation variables from AHA are for a changing mix of employees. (Although hospitals shifted to a more expensive mix of employee hours in the study period, the magnitude of the shift was small—less than 2 percent cumulatively from 1980 to 1989 [Donham, Maple, and Lemieux, 1990].)
Table 4
Number of hospitals, admissions per hospital, average length of stay, and total days per hospital: 1977-89

| Report year | Number of hospitals | Admissions per hospital | Average length of stay | Total days per hospital |
|-------------|---------------------|-------------------------|------------------------|------------------------|
|             | Number of hospitals | Number                  | Days                   | Number                 | Percent change | Percent change | Number | Percent change |
| 1989        | 4,968               | 5,295.4                 | 7.0                    | 37,012                 | 0.2            | 0.8            | 1.0    |
| 1988        | 5,034               | 5,284.2                 | 7.0                    | 36,644                 | 1.0            | 0.5            | 0.0    |
| 1987        | 5,104               | 5,233.6                 | 7.0                    | 36,476                 | -1.4           | 1.5            | 0.0    |
| 1986        | 5,166               | 5,309.4                 | 7.0                    | 36,471                 | 2.6            | 0.9            | 1.8    |

### Figure 1
Percent change in the Consumer Price Index for hospital services (list prices) and estimated hospital output transaction prices: 1978-89

---

**SOURCE:** U.S. Department of Labor, Bureau of Labor Statistics: *CPI Detailed Report*, Washington. U.S. Government Printing Office. Monthly reports for Oct. 1977-Sept. 1989; (American Hospital Association, 1977-89); Health Care Financing Administration, Office of the Actuary: Estimates from the Office of National Health Statistics, Division of Health Cost Analysis.
The major source of increase in hospital input prices in almost all years of the study period was labor compensation (i.e., employee wages and salaries and employee benefits per FTE worker), which generally rose much faster than the price of non-labor inputs over the period (Table 8).

In the later PPS period, rising resource input prices (i.e., expenses/inputs) accounted for most of the increases in hospital expenses, with rising outputs as a major secondary source (Table 9). Total factor productivity rates generally decreased in the VB period, as outputs decelerated relative to input resources, but increased in the immediate pre-PPS period. In the initial PPS period, total factor productivity rates declined, as the reduction in input resources lagged behind rapidly decreasing outputs. However, as input resource adjustments were made in later periods, productivity rates stopped decreasing throughout the later PPS period.

In Table 10, I disaggregate changes in total factor productivity rates into a direct-labor component and a non-direct-labor component (which includes productivity factor components for capital and other non-labor inputs). Changes in direct-labor productivity were computed by dividing changes in real outputs by changes in FTE employees. Direct-labor productivity increased at a declining rate in the first year of PPS, 1984, decreased in 1985, and subsequently increased. Changes in non-direct-labor productivity were computed by subtracting expenditure-weighted direct-labor productivity changes from expenditure-weighted total-factor productivity changes. Changes in non-direct-labor productivity were negative for almost all the pre-PPS periods through 1986.

Two warnings about productivity estimates in Table 10 should be noted. First, anecdotal data suggest that the rate of change in industry use of contract labor is increasing. Because the number of contracted labor units is excluded from the FTE data in Table 10, computations of hospital labor productivity are inaccurate to the extent that they exclude contract labor. Second, the flow of capital services provided by a given stock of existing real hospital capital has not been determined.

### Net profits

Net profits as a percent of total net revenues gradually increased during the VE and pre-PPS periods, rapidly increased in the initial PPS period, and subsequently slowed to pre-PPS period rates in later years (Table 1). By the end of the study period in 1989, the average PPS hospital was accumulating about $1.3 million in net profits annually.

The ratio of total net revenues to expenses changes because total revenues per unit of output change and because expenses per output change. Generally, hospital revenues per output kept pace with expenses computed by subtracting expenditure-weighted direct-labor productivity changes from expenditure-weighted total-factor productivity changes. Changes in non-direct-labor productivity were negative for almost all the pre-PPS periods through 1986.

### Table 7

| Year       | Wages and salaries | Benefits | Total compensation | Hourly wages | Benefit per FTE | CPI All Items | Percent change in real wages |
|------------|---------------------|----------|--------------------|--------------|----------------|---------------|-----------------------------|
| 1989       | $24,253             | 5.2      | $4,776             | 10.1         |                | 122.6         | 4.8                         |
| 1988       | 23,056              | 6.5      | 4,338              | 7.9          |                | 117.0         | 4.1                         |
| 1987       | 21,540              | 4.3      | 4,020              | 3.4          |                | 112.4         | 2.9                         |
| 1986       | 20,748              | 4.2      | 3,888              | 1.4          |                | 109.3         | 2.5                         |
| 1985       | 19,903              | 4.1      | 3,834              | 6.0          |                | 106.6         | 3.7                         |

SOURCE: FTEs from (American Hospital Association, 1977-89).
Trends in net revenues and, therefore, profits have tended to decline. Since 1986 and 1987, expenses per unit of output tended to drift above revenues per unit of output. Since 1986 and 1987, expenses per unit of output accelerated relatively faster than expenses per unit of output. Since 1986 and 1987, revenues and expenses have resumed their historical trends.

Trends in net revenues

Although expenses per PPS hospital rose rapidly in recent years as a result of rising outputs and input resource prices, the average PPS hospital was able to maintain its pre-PPS profit rates by rapidly increasing its net revenues. Some erosion of profit margins is observed in recent periods, beginning from the relatively high profit rate observed in the early PPS period. These trends are summarized in Table 12, which shows specific amounts for the identity:

$$\text{Net revenues} = (\text{Expenses}) \times \left(\frac{\text{Net Revenues}}{\text{Expenses}}\right)$$

Table 12 shows that hospital net revenues have kept pace with increasing costs in recent years. The table also indicates that rising input prices have been a consistent contributor throughout the study period, accounting for more than one-half of growth in net revenues in recent years. Rising outputs were another major source of increase in all other years except 1984 and 1985, when net profits replaced them.

Hospital expenditures and economic growth

Total expenditures for hospital care (i.e., net revenues) are the product of average net revenues per hospital and the number of hospitals. Although average net revenues per hospital increased steadily over the study period, the number of hospitals steadily decreased. Therefore, in order to estimate changes in total hospital expenditures, the rates of change in average revenues per hospital and in outputs per hospital obtained in prior sections must be adjusted by changes in the number of hospitals. These adjustments to hospital revenues and outputs are shown in Table 13.

Net hospital revenues consistently grew more rapidly than the GNP before PPS was implemented in FY 1984, grew less than the GNP in the initial PPS period, and resumed faster growth in the later PPS period. By 1989, hospital revenues grew nearly 2 percentage points faster than the GNP (Table 13). The major eras of changing growth patterns were:

- 1977 through 1979, the industry's effective VE cost-control period, when hospital revenues exceeded GNP growth by 1.6 percent annually.
- 1979 through 1983, an era with no effective cost-control program, when hospital revenues exceeded GNP growth by 7.8 percent annually.
- 1983 through 1985, the PPS implementation period, when hospital revenues grew 2.1 percent less annually than the GNP.
- 1985 through 1989, the later PPS implementation period, when hospital revenues grew 1.3 percentage points faster than the GNP.

Hospital total output transaction prices grew substantially faster than general prices (as measured by the GNP implicit price deflator) in all years of the study except 1986 and 1987, when third-party payers, particularly Medicare, sharply limited rates of increase in payment rates.

Hospital real outputs generally grew less than real outputs in the general economy during the initial periods of the two hospital cost-containment programs implemented in the study period. Thus, real hospital outputs grew less than general real economic growth in the VE period and again in the initial PPS period.

Changes in hospital real outputs tended to exceed changes in general economy real outputs in all other periods (Table 13 and Figure 3).

Over the entire study period, 1977 through 1989, hospital revenues rose at an average annual rate of 2.9 percent faster than the GNP (Table 13 and Figure 3). Hospital spending trends in Table 13 include personal health care consumption spending but exclude hospital investments in construction and equipment (not shown in this article). To the extent that hospital investment rate changes differ from hospital consumption rate changes, the ratio of change in hospital spending to changes in the GNP will vary. The preliminary estimate is that changes in hospital investment spending rates do not differ markedly from changes in hospital consumption rates shown in Table 13.

I previously showed how hospital output prices could be derived directly from list prices. Total hospital output prices can also be considered as the product of input prices, productivity rates, and profit rates. This relationship is shown in the identity:

Table 11

| Fiscal year | Percent change per unit of output | Difference (revenues less expenses) |
|-------------|----------------------------------|-----------------------------------|
| 1989        | 5.9                              | 5.0                               |

| 1979-83    | 10.9    | 8.4     | 0.3     |         |         |
| 1977-79    | 8.4     | 0.3     |         |         |         |

Hospital output prices =

\[
\text{Total net revenues/Outputs} = \left(\frac{\text{Inputs}}{\text{Outputs}}\right) \times \left(\frac{\text{Expenses}}{\text{Inputs}}\right) \times \left(\frac{\text{Total net revenues}}{\text{Expenses}}\right)
\]

The identity shows that a 1-percent increase in input prices translates directly into a 1-percent increase in output prices, unless changes in productivity rates or profit rates offset or supplement the input price increase. During the study period, the major determinant of rising output prices was rising input prices (Table 14). The major determinant of rising input prices in the period was hospital labor compensation (Table 8).

The impact of rising hospital compensation rates can be observed in the growing differences in real wage rate changes in the hospital sector compared with the general economy. Over the 12-year study period, 1977 through 1989, real hospital wages (i.e., nominal hospital wages divided by the CPI for all items) rose more than 20 percent, while real private non-agricultural wages declined nearly 10 percent (Table 7 and Figure 2). Victor Fuchs reports that "From 1977 to 1987, wages in most industries failed to keep pace with inflation, but rank-and-file health workers did better, outpacing employees in the rest of the economy by 1.3% per annum," and that "In 1949, rank-and-file health care workers (16 years of schooling or less) earned 15% less than their counterparts in the rest of the economy. In 1985 they earned 7% more than other workers [which] implies that relative wages rose at the rate of 0.6% per annum" (Fuchs, 1990).

Data sources and limitations

Hospital data for Tables 1 through 14 were obtained from Hospital Statistics, an annual publication of the American Hospital Association. Data are shown for all community hospitals in the United States from this source except for hospitals in the States of Maryland, Massachusetts, New Jersey, and New York. Data for Tables 15 through 19 were obtained from a linked file of Medicare Cost Reports for 5,161 providers for cost report years 1985 through 1989. Data from Medicare Cost Reports and AHA annual surveys are reported for provider reporting periods, which generally do not coincide with Federal FY periods. Thus, the characterization of hospital-related

NOTE: Data for Maryland, Massachusetts, New Jersey, and New York are excluded.

1977-79 8.4 2.0 0.3 10.6

\(^1\) Input price market basket.  
\(^2\) Inverse of total factor productivity.  
\(^3\) Relative profit ratio.

NOTE: Data for Maryland, Massachusetts, New Jersey, and New York are excluded.

SOURCE: Expenses and net revenues from (American Hospital Association, 1977-89).

Financial data as "fiscal year" data in this article is not strictly accurate.

The relationship between list and transaction prices follows from definitions of these two prices:

Let:

- \(P_L\) = List price
- \(P_{PT}\) = Patient care output transaction price
- \(G\) = Gross patient revenues
- \(N\) = Net patient revenues
- \(O\) = Number of patient care outputs

Then:

- \(P_L = G/O\)
- \(P_{PT} = N/O\)
- \(P_{LT}/P_{LT0} = (P_{LT}/P_{LT0})/(G_N/G_N)\)

For rates of change between period "0" and period "1,"

- \(P_{PT1}/P_{PT0} = (P_{LT1}/P_{LT0})/(G_N1/N_N)/(G_N0/N_N0)\)

Technical note

Medicare Cost Report data trends

In order to portray characteristics of hospitals under PPS that are not available from the AHA annual surveys, I prepared a data file of 5,161 hospitals that were continuously under PPS for all cost report years 1985 through 1989. Revenue, expense, and balance sheet data in Table 15 were estimated from subsets of Medicare Cost Reports, which reasonably represented the universe of 5,161 hospitals whose income and expense data are shown in Table 15, because some hospitals did not report balance sheet data.

Alternative measures for trends in hospital wages and/or benefits shown in Table 7 are sometimes used in various input price market baskets:

- Bureau of Labor Statistics series including Hospital Average Hourly Earnings for private hospital non-supervisory workers and Employment Cost Index (ECI) series for private and State and local hospital workers.
- American Hospital Association panel survey wage and benefit data.

Trends in these alternative measures generally parallel the measure shown in Table 7 in direction but not always in magnitude.

Balance sheet data in Table 17 were estimated from subsets of Medicare Cost Reports, which reasonably represented the universe of 5,161 hospitals whose income and expense data are shown in Table 15, because some hospitals did not report balance sheet data.

Technical note

Medicare Cost Report data trends

Some PPS providers are defined as hospitals in the Medicare Cost Report File but are not included in the AHA data because they are not community hospitals as defined by AHA.

Generally, trends shown in Table 15 for revenues and expenses parallel trends for the same data shown in Tables I through 14, except that expenses per hospital from the AHA survey data generally increase faster than expenses per hospital from the Medicare Cost Report data. I attribute this factor primarily to lower productivity rate changes in the AHA survey data (Table 9), compared with productivity rate changes in the Medicare Cost Report data (Table 16).

These differences in productivity rate changes appear to be related to differences in the hospitals studied in the two sources. The AHA data include all hospitals reporting in the period, while the Medicare Cost Report data include only hospitals that succeeded in remaining in business for the entire period. Thus, it is no surprise that the Medicare Cost Report data show higher profits and profit rates than the AHA data (Table 1 and Table 14).

To supplement the analysis of trends in hospital income and expenses shown in Table 15, I have provided balance sheet data showing trends in assets, liabilities, and fund balances for the "typical" hospital in the Medicare Cost Report data (Table 17). Key relationships revealed by the balance sheets are shown in a series of ratios in Table 18. The ratio concepts and their import were obtained from Essentials of Hospital Finance by William O. Cleverly (1978).

Liquidity ratios. Trends in measures of short-term liquidity indicate a relative decline in the average hospital's ability to meet its short-term obligations. The "current ratio" (i.e., the ratio of current assets to current liabilities) decreased steadily during the study period but still was above 2.00 at the end of 1989. Both the "days in accounts ratio" (net accounts receivable/operating revenues/365) and the uncollectible rate (uncollectible notes and accounts/operating revenues/365) increased during the period.

Capital structure ratios. Trends in measures of long-term liquidity indicate a relative decline in the average hospital's ability to meet its long-term obligations. The ratio of fund balances to total assets, an indicator of the percentage of assets that has been financed with sources other than debt, declined over the period, while the ratio of long-term debt to fund balances and the ratio of long-term debt to fixed assets increased.

NOTE: Data based on Medicare Cost Reports for 5,161 hospitals that were under the prospective payment system in Federal fiscal years 1985-89.

### Table 19

**Capital-related expenses as a percent of total expenses: 1985-89**

| Fiscal year | Total expenses | Total depreciation | Total interest | Other | Leases and rentals |
|-------------|----------------|--------------------|---------------|-------|-------------------|
| 1989        | $30,350        | $2,643             | $1,690        | $892  | $61               |
| 1988        | 27,394         | 2,589              | 1,502         | 813   | 54                |
| 1987        | 24,403         | 2,372              | 1,359         | 766   | 47                |
| 1986        | 22,973         | 2,173              | 1,259         | 710   | 43                |
| 1985        | 21,365         | 1,945              | 1,137         | 836   | 39                |

**Dollar amounts per hospital in thousands**

| Fiscal year | Total expenses | Total depreciation | Total interest | Other | Leases and rentals |
|-------------|----------------|--------------------|---------------|-------|-------------------|
| 1989        | 100.0          | 10.0               | 6.7           | 5.6   | 0.2               |
| 1988        | 100.0          | 9.8                | 6.6           | 5.6   | 0.0               |
| 1987        | 100.0          | 9.5                | 6.7           | 5.5   | 0.0               |
| 1986        | 100.0          | 9.5                | 6.7           | 5.5   | 0.0               |
| 1985        | 100.0          | 9.1                | 6.5           | 5.3   | 0.0               |

**Percent of total expenses**

| Fiscal year | Total expenses | Total depreciation | Total interest | Other | Leases and rentals |
|-------------|----------------|--------------------|---------------|-------|-------------------|
| 1989        | 100.0          | 10.0               | 6.7           | 5.6   | 0.2               |
| 1988        | 100.0          | 9.8                | 6.6           | 5.6   | 0.0               |
| 1987        | 100.0          | 9.5                | 6.7           | 5.5   | 0.0               |
| 1986        | 100.0          | 9.5                | 6.7           | 5.5   | 0.0               |
| 1985        | 100.0          | 9.1                | 6.5           | 5.3   | 0.0               |

1Includes insurance, taxes, and licenses on capital stock.

**Source:** Health Care Financing Administration, Bureau of Data Management and Strategy: Data from the Medicare Cost Report File, 1985-89.

- **Activity ratios.** Some measures of efficiency show upward trends over the period. Both the "total asset turnover ratio" (i.e., the ratio of operating revenues to total assets) and the "fixed asset turnover ratio" (i.e., the ratio of operating revenues to fixed assets) generally increased over the period. Another measure, the "current assets ratio" (i.e., the ratio of operating revenues to current assets), is stable. A final measure, the "accounts receivable turnover ratio" (i.e., the ratio of operating revenues to accounts receivable), is declining.

- **Profitability ratios.** Measures of ability to meet financial requirements of the hospital generally show declines from early years of the PPS and stability in recent years. Both the "net profit rate" (i.e., the ratio of net profits to total net revenues) and the "return to total assets" (i.e., the ratio of net profits to total assets) remained relatively stable from the 1986 report year through the 1989 report year.

Any conclusion about the deterioration or improvement in the average hospital’s ability to meet its future obligations that is based on the ratios obtained from balance sheets should be tempered by consideration of alternative financing procedures that hospitals have adopted in recent years. Many hospitals have shifted from purchasing capital stock to leasing capital stock in recent years. The dollar amounts of the leased capital stock do not appear in the hospital’s balance sheet, which is restricted to descriptions of its own capital stock. However, leasing costs do appear as expenses and comprise an increasing proportion of capital-related and total expenses (Table 19). (Data on leasing costs are not explicitly shown in Medicare Cost Reports and, therefore, have been estimated in Table 19 from other data sources, particularly a recent U.S. Bureau of the Census survey of capital expenditures.)

No adequate national balance sheet data are available for pre-PPS periods. Therefore, it is not possible to determine whether the observed ratio trends in Table 18 represent a return to normal pre-PPS performance or whether they represent a significant departure from pre-PPS performance.
