Predominance of Gram-negative infections a cause of neonatal sepsis among low birth weight preterm infants

Xinlu Bai, Qiang Wei, Taimei Duan, Yuling Yi, Hong Peng and Liyi Hu*

Abstract

Objectives: Neonatal sepsis continues to be a leading and most important cause of mortality among low birth weight (LBW) preterm infants.

Methods: The study group included 226 LBW preterm infants with sepsis. A total of 100 normal birth weight infants with sepsis served as control. Blood and cerebrospinal fluid (CSF) samples collected for microbiological culture and processed according to standard protocol. Antibiotic resistance patterns were performed following standard guidelines.

Results: Out of 226 LBW preterm infants 106 (46.9%) showed positive blood culture, of which 52 (49%) *Escherichia coli*, 28 (26.4%) *Klebsiella pneumoniae*, 12 (11.32%) *Enterobacter* spp., 4 (3.7%) *Pseudomonas aeruginosa*, 2 (1.88%) *Acinetobacter* spp., 5 (4.7%) methicillin-resistant *Staphylococcus aureus* (MRSA), 3 (2.8%) *Staphylococcus epidermidis* were isolated. Out of 100 control group infants, 46 (46%) showed positive blood cultures, of which 18 (39.1%) *E. coli*, 12 (26.08%) *Enterobacter* spp., 8 (17.39%) *K. pneumoniae*, 1 (2.17%) *P. aeruginosa*, 2 (4.34%) MRSA, 3 (6.52%) *S. epidermidis* and 2 (4.34%) *Candida* spp. were isolated. Cephalosporin and Penicillin group showed highest resistance with 58% and 52%, respectively. Aminoglycosides showed 22% resistance. The control group showed highest resistance of 62% to the Penicillin group, 54% cephalosporin and 18% for aminoglycosides.

Conclusions: Our study highlights on the surveillance of resistant pathogens causing sepsis in LBW preterm infants emphasizing antimicrobial stewardship to control the mortality rate.

Keywords: antibiotic resistance; infection; neonatal sepsis; pathogens; preterm newborns.

Introduction

Neonatal sepsis is a leading cause of morbidity and mortality among low birth weight preterm infants (LBWI) [1–3]. The causative organisms influence the risk of complication. LBW preterm infants are more prone for infections mainly because of their underdeveloped immune systems. Prolonged hospital stay and central venous catheterization are also other main cause of Neonatal sepsis in LBW preterm infants [4, 5]. Among developed countries an incidence rate of 10–25% of LBW preterm infants developing sepsis had been reported [6]. In a study 35% of mortality was reported among newborn with sepsis in low birth weight infants compared to 11% mortality in uninfected low birth weight infants [7].

Neonatal sepsis with known risk of mortality the survivors of neonatal sepsis had been reported to develop more severe morbidity like pulmonary hypertension, respiratory shock and failure [8]. A change in the pathogen distribution has been reported by Neonatal Research Network among the low birth weight infants born before 1993 and after 2000. Gram-positive microbes were found to be common pathogens during early periods but later Gram-negative microbes predominated.

Among neonates systemic infections caused by bacteria occurs due to predisposing factors such as prematurity, premature membrane rupture, poor maternal nutrition, low birth weight, maternal conditions, duration of life support procedures required for postnatal period. The pattern of organism in neonatal sepsis among LBW preterm infants is changing constantly [9]. Over the period of time there is a change in the group of organisms. Among the developed countries the most common cause of neonatal sepsis are Gram-negative pathogens [10].
Unless proper treatment is not given neonatal septi-
cemia can be life threatening. Neonatal sepsis present with
non-specific signs and symptoms which complicates the
clinical diagnosis. With availability of varies diagnostic
modalities for neonatal sepsis such as total blood count,
erythrocyte sedimentation rate (ESR), C-reactive protein,
platelet count but gold standard is blood culture [11].

An insight about common organism and their suscepti-
bility pattern in neonatal sepsis is required to select proper
antibiotic treatment to reduce the infant mortality and
morbidity. The resistance pattern vary according to
geo graphical location, pathogen and antibiotics commonly
used in the neonatal wards [12]. It has been a great challenge
in the management of neonatal septicemia along with
emerging drug resistance to combat infection. Ongoing re-
view on the microbiological pattern and antibiotic resistance
pattern among neonatal septicemia is highly needed [13].

The frequent emergence of drug resistance in bacteria
compounds the problem among LBW preterm infants. The
resistance pattern and the etiological agent of the LBW
infants varies based on the geographical area. This study
was undertaken to know the changing pattern of Gram-
negative infection among LBW infants and to highlight on
the need for surveillance on neonatal sepsis and their
resistance pattern of the pathogens isolated.

Materials and methods

A total of 226 LBW infants of 425–1,600 g born at the Chinese hospital
between Jan 2017–Oct 2019 and those infants who survived more than
14 h were included in our study. 100 control group includes normal
birth weight infants of 2,400–3,500 g with sepsis were included.

Blood or cerebrospinal fluid (CSF) cultures were obtained from
LBW infants after development of symptoms. 2–3 blood cultures were
taken from infants at late stage diagnosed with sepsis. All samples were
collected before administration of antibiotics. All the demographic
details such as age, sex, previous pregnancy were taken from the hos-
pital record. All the parents were informed about the study and
informed consent were obtained from the parents. Only those who gave
consent were included in our study. Babies on prior antibiotic treatment
and with congenital anomalies were excluded from the study. The study
was approved by Institutional Ethical Board (IRB29/10456/2017).

The samples were processed according to standard protocol. The
criteria included for evaluation are sepsis criteria, age of gestation, age
at onset of symptoms, sex, birth weight, organism isolated and the
pattern of antibiotic susceptibility. Those LBW infants with fever,
apnoea, trachypnea, lethargy, poor feeding were diagnosed as to have
sepsis. Other biochemical investigations were done like total white
blood cell count, differential blood count, total neutrophil ratio, ESR,
C-reactive protein, CSF examination, blood glucose level estimation,
serum calcium, creatinine, electrolyte were tested.

A total of 2 mL of blood were inoculated into Bactec pediatric
blood culture bottles and loaded into BACT/ALERT 460 blood culture
system the samples were incubated for seven days. Positive bottles
were sub cultured on to trypticasoy agar with 5% sheep blood,
eosin methylene blue (EMB) agar, chocolate agar, Mac Conkey agar
(HiMedia), daily for seven days. Blood agar and chocolate agar plates
were incubated in 5–10% CO2 using Candle jar at 37°C for 24–48 h. Mac
Conkey plates were incubated aerobically. After seven days of incubation
blood culture bottles showing no growth were reported as negative. The bacterial species were identified by conventional
methods. All the blood samples collected were processed following
standard guidelines [14].

The antimicrobial testing was performed following standard
guidelines by Kirby Bauer disc diffusion method. The following anti-
biotics were used ampicillin/sulbactam (10/10 μg), gentamicin (10 μg),
cefotaxime (30 μg), ceftriaxone (30 μg), ofloxacin (5 μg), meropenem (10 μg), amikacin (30 μg), cotrimoxazole (25 μg), piperacillin/tazo-
bactam (100/10 μg). Escherichia coli ATCC25922 and Staphylococcus
aureus ATCC 25923 were used as quality control standards for anti-
microbial susceptibility testing [15].

Statistical analysis

The data collected were analyzed by SPSS software version 20.0 to
determine the changes in overall sepsis rate, rate of infection specific
to pathogen were analyzed.

Results

Out of 226 blood cultures received from LBW infants 106
(46.9%) showed blood culture positive, 31 (13.7%) grew
contaminants and 89 (39.38%) showed no growth for
bacteria. Out of 100 blood cultures from control group 46
(46%) showed positive for blood culture. A total of 28 (28%)
grew contaminant, 26 (26%) showed no growth (Figures 1, 2).
The mean gestational age for infants with neonatal
septicemia was 25.4 weeks (95% C.I: 24.4, 25.8) and
27.1 weeks (95% C.I: 27.5, 28.4), respectively. Sepsis caused
by Gram-negative microorganisms higher than caused by
Gram-positive microorganisms (p<0.0001).

Blood culture positive among study group
population

![Blood culture positive](Figure 1: Distribution of blood culture positive among study group population.)
Out of 106 blood culture positive neonates 66 (62.26%) were inborn, 40 (37.74%) were out born neonates (Table 1). Of which 57 (53.77%) were males and 49 (46.23%) were females (Table 2). Among control group out of 46 positive blood culture 27 (58.7%) were inborn and 19 (41.30%) were out born neonates (Table 1). Among 46 neonates 28 (60.86%) were male and 18 (39.14%) were females (Table 2).

Neonatal septicemia caused by Gram-negative isolates were 98 (92.45%) compared to Gram-positive organism 8 (7.55%) causing neonatal septicemia (Figure 3). Sepsis caused by Gram-negative microorganisms higher than caused by Gram-positive microorganisms (p<0.0001). Out of 106 blood culture seven bacterial isolates were isolated. *E. coli* 52 (49%), *Klebsiella pneumoniae* 28 (26.4%), *Enterobacter* spp. 12 (11.32%), *Pseudomonas aeruginosa* 4 (3.7%), *Acinetobacter* spp. 2 (1.88%), methicillin-resistant *S. aureus* (MRSA) 5 (4.7%) and *Staphylococcus epidermidis* 3 (2.8%) were isolated from our study (Table 3).

Among control group neonatal septicemia Gram-negative isolates were 39 (84.8%) isolated and Gram-positive isolates were 5 (10.9%) and candida 2 (4.3%) were isolated. Among the control group 18 (39%) were *E. coli*, 12 (26.08%) was *Enterobacter*, 8 (17.39%) was *K. pneumoniae*, 1 (2.17%) was *Pseudomonas*, 2 (4.34%) were MRSA, 3 (6.52%) were *S. epidermidis* and 2 (4.34%) were *Candida* spp. In our study *E. coli* (46.05%) was isolated being the most common pathogen from study and control group population (Table 4).

The following antibiotics were used ampicillin/sulbactam (10/10 μg), gentamicin (10 μg), cefotaxime (30 μg), ceftriaxone (30 μg), ofloxacin (5 μg), meropenem (10 μg),
amikacin (30 μg), cotrimoxazole (25 μg), piperacillin/tazobactam (100/10 μg). *E. coli* ATCC25922 and *S. aureus* ATCC 25923 were used. In our study highest resistance was observed for cephalosporin group of antibiotics with 58% resistance followed by penicillin group with 52% resistance. Aminoglycoside group showed least resistance with 22% β-lactam antibiotics showed highest sensitivity of 96% sensitivity (Table 5).

In control group penicillin group of antibiotics showed highest resistance with 62% followed by cephalosporin group with 54% resistance. 18% resistance was observed for aminoglycoside group. Beta lactam group of antibiotics showed highest sensitivity of 97.5% (Table 6).

## Discussion

In the neonatal intensive care unit (NICU) the leading cause of infant mortality and morbidity is neonatal septicemia, especially LBW infants has higher mortality and morbidity rate [16, 17]. Overall infection rate has changed during past 13 years with decline in Gram-positive infection and raise in Gram-negative bacterial infection since 2000. The most troubling and important observation in our study is Gram-negative infections are high among LBW infants with septicemia. The most frequently isolated pathogen in our study is *E. coli* which is similar to the study by Stoll et al. 2005 [8]. The incidence of infection in NICU varies from 6 to 25% in USA, recent studies have reported 48% of neonatal sepsis [18]. Haque et al. [19] also reported a higher incidence of neonatal sepsis up to 48%. In our study we have an overall incidence of 46.9% correlating with other studies. Al Shamahy et al. 2012 [20] reported 57%. The variation in the positivity of blood culture among neonatal septicemia may be due to difference in sample size, prior antibiotic administration before sample collection, infection due to anaerobic organisms are the reasons [21].

In our study neonatal septicemia was more common among males with 53.77 and 46.23% females in control group population also showed male predominance with 60.86% male and 39.14% female which coincides with other studies showing septicemia incidence rate with male ranging from 59–82% [22]. A further investigation on the pathophysiology of sepsis in neonates is required to get an insight in the diagnosis, treatment and management of the sepsis [13].

In our study majority of the isolates were Gram-negative with 92.45% which is high compared to Thapa and Sapkota et al. 2019 [13] had reported 69.6% of Gram-negative isolates from their study other studies had higher incidence of Gram-positive pathogens being predominant in their study [23]. Neonatal septicemia causative agents will change from time to time and vary according to geographical locations [24].

In our study the commonest and predominant pathogen is *E. coli* which is similar to study by Kumaravel et al. 2016 [25]. In a study conducted by Mutlu et al. 2011 also reported *E. coli* to be the most common organism isolated among neonatal sepsis. A high degree of antimicrobial resistance is observed among Gram-negative microorganism.

Couto et al. 2007 [26] had reported highest resistance to third generation cephalosporin for *E. coli* and *Klebsiella* spp. ranging from 19 to 64%, which is high compared to our study with 58% resistance observed for cephalosporin group of antibiotics. Control group also showed 54% resistance for cephalosporin group.

In our study all the Gram-negative isolates showed highest resistance for cefotaxime antibiotic among the cephalosporin group. Penicillin group also showed highest resistance with 52% in study group and 62% resistance in control group population which is similar to Aurangzep and Hamed et al. studies [27]. Least resistance was observed for aminoglycoside group of antibiotics with resistance of 22% in study group and 18% in control group which coincides with the study by Mutlu et al. 2011 [28]. The empirical antibiotic administration as treatment is not effective against all microorganisms. Culture reports with antibiotic susceptibility should be obtained as early as possible.

Higher resistance reported in last five years may be due to emerging resistant bacterial strain because of inappropriate and irrational use of antibiotics in many private clinics and primary health care facilities [29]. Firm hospital infection control policy and hand hygiene prevent transmission of infection especially in neonatal ward. Expanded

surveillance of the microorganism involved in LBW infants and data including infants of all birth weights is required to get clear data on the infections [13].

Limitations

More clinical studies and epidemiological data are required to curb the changes in neonatal sepsis among LBW infants.

Conclusions

High degree and emerging antibiotic resistance are significantly associated with mortality and morbidity in neonatal sepsis infants. Routine antimicrobial surveillance and periodic antibiotic cycling with national antibiotic policy helps to decrease the burden of antibiotic resistance in LBW infants with neonatal sepsis.
