Genomic landscape of the immune microenvironments of brain metastases in breast cancer

Wei‑cheng Lu1, Hui Xie2, Ce Yuan3, Jin‑jiang Li4, Zhao‑yang Li5 and An‑hua Wu1*

Abstract

Background: This study was intended to investigate the genomic landscape of the immune microenvironments of brain metastases in breast cancer.

Methods: Three gene expression profile datasets (GSE76714, GSE125989 and GSE43837) of breast cancer with brain metastases were downloaded from Gene Expression Omnibus (GEO) database. After differential expression analysis, the tumor immune microenvironment and immune cell infiltration were analyzed. Then immune‑related genes were identified, followed by function analysis, transcription factor (TF)‑miRNA–mRNA co‑regulatory network analysis, and survival analysis of metastatic recurrence.

Results: The present results showed that the tumor immune microenvironment in brain metastases was immunosuppressed compared with primary cancer. Compared with primary cancer samples, the infiltration ratio of plasma cells in brain metastases samples was significantly higher, while the infiltration ratio of macrophages M2 cells in brain metastases samples was significantly lower. Total 42 immune‑related genes were identified, such as THY1 and NEU2. CD1B, THY1 and DOCK2 were found to be implicated in the metastatic recurrence of breast cancer.

Conclusions: Targeting macrophages or plasma cells may be new strategies for immunotherapy of breast cancer with brain metastases. THY1 and NEU2 may be potential therapeutic targets for breast cancer with brain metastases, and THY1, CD1B and DOCK2 may serve as potential prognostic markers for improvement of brain metastases survival.

Keywords: Breast cancer, Brain metastases, Immune, Gene

Background

The incidence of brain metastases in cancer patients is rising, which may be due to the improvements in systematic therapies to control extracranial disease and prolong the survive of patients. Thus, patients who previously may have died sooner from other manifestations of the disease may develop brain metastases [1]. Breast cancer is the second most common cause of brain metastases following lung cancer [2]. It has been estimated that 20 to 30% of breast cancers develop brain metastases [3]. Brain metastases are serious complications of cancer with median survival of about 15 months and there is no effective long‑term treatment [4, 5]. Therefore, brain metastases have become a major limiting factor in life expectancy and quality of life for many patients [2]. Understanding the biological mechanisms of brain metastases is crucial to predict patients at risk of brain metastases and to identify new therapeutic targets.

The interactions between immune and tumor cells have played an important role in malignant progression [6]. The brain was previously considered as an immunologically privileged organ because the intact brain has almost no lymphocytes [7]. Actually, the central nervous system...
is an immune specialized site under a tight regulatory network linking astrocytes, microglia, and lymphocytes [8]. T cells and B cells have been found around the tumors of brain metastases [9]. Despite the immune microenvironments of brain metastases in breast cancer have been studied [10, 11], the genomic landscape of breast cancer with brain metastases remains to be investigated.

In this study, we downloaded three gene expression profile datasets of breast cancer with brain metastases from Gene Expression Omnibus (GEO) database and analyzed the tumor immune microenvironment at genetic level (Fig. 1). Some immune-related genes were identified, which may contribute to the development of immunotherapy to treat breast cancer patients with brain metastases.

**Methods**

**Data sources**

Three expression profile datasets (GSE76714 [12], GSE125989 [1] and GSE43837 [13]) were downloaded from GEO database. GSE76714 included 71 triple negative breast cancer samples, including 48 primary triple negative breast cancer samples and 23 triple negative breast cancer with brain metastases samples, which was based on the platform of GPL14951 Illumina HumanHT-12 WG-DASL V4.0 R2 expression beadchip. GSE125989 contained 16 primary breast cancer samples, 16 paired breast cancer with brain metastases samples. The detection platform was GPL571 [HG-U133A_2] Affymetrix Human Genome U133A 2.0 Array. In GSE43837, there were 19 HER2+ primary breast cancer samples and 19 HER2+ breast cancer with brain metastatic samples. The platform was GPL1352 [U133_X3P] Affymetrix Human X3P Array.

**Data downloading and preprocessing**

The series matrix file(s) of GSE76714 was downloaded and normalized using quantile normalization with the beadarray library in R. The probe ID was converted into gene symbol using illuminaHumanWGDASLv4 package in R. The probes that did not correspond to gene symbol were removed. For the case where different probes

---

**Fig. 1** The flow diagram of the analysis
mapped to the same gene, the mean value of different probes was taken as the final expression value of the gene. The FactoMineR package [14] was used for principal component analysis and clustering. The processing flows of GSE125989 and GSE43837 datasets were similar to that of GSE76714. GSE43837 data were transformed by log2(x+1), and GSE125989 data were normalized by MASS algorithm of R language package, and transformed by log2. The microarray annotation packages of the GSE125989 and GSE43837 datasets were u133x3p.db and hgu133a2.db, respectively.

### DEGs identification

The modified empirical Bayes t test method provided by limma package [15] (version 3.40.6) was used for differential expression analysis of brain metastasis group vs. cancer group. All RNAs (including miRNAs and lncRNAs) were analyzed to obtain the p value and log fold change (FC). The thresholds of DEGs screening were set as follows: p value < 0.05 and |logFC| > 0.585.

The ggscatter function of ggpubr package [16] (version 0.2.2) was used to draw the volcano plot, and the DEGs with the top 10 |logFC| were labeled in the volcano plot. The clustering heatmaps of DEGs were drawn using the pheatmap package [17] of R language.

### Tumor immune microenvironment analysis

The stromal score, immune score and ESTIMATE score of all samples were calculated using the ESTIMATE algorithm [18] (version 1.0.13). The difference of these scores between brain metastatic tumor and primary tumor tissues were analyzed through T test, and the boxplot was drawn by using the R package ggpubr. Additionally, the cytolytic activity score of all samples was calculated and the differences of score between brain metastatic tumor and primary tumor tissues were also analyzed using T test. The boxplot was drawn by the R package ggpubr as well. Validation for the above scores was performed in the GSE125989 and GSE43837 datasets.

### Immune cell infiltration abundance analysis

The abundance matrix of immune cells in the samples was estimated using the CIBERSORT deconvolution algorithm [19], and the infiltration abundance of immune cells in the samples was analyzed, with parameters of perm = 200 and QN = FALSE. The proportion difference of immune cell subgroups between two groups was calculated, and relevant landscape map (barplot), clustering heatmap (pheatmap), correlation heatmap (corHeatmap), and violin plot (vioplot) were drawn by R language. The immune cell subgroups with significant differences between groups were screened with threshold of p value < 0.05. The datasets of GSE125989 and GSE43837 were used for validation.

### Identification of immune-related DEGs

Using the R corrplot package [20], spearman correlation test was conducted on the DEGs and infiltration abundance of differential immune cell subsets, and the DEGs with p value < 0.05 and correlation coefficient |r| > 0.30 were screened, which were considered as the DEGs related to immune cell subgroup. The ggboxplot function of the ggpubr package in R language was used to plot the boxplot of the expression of immune-related genes between two groups, and the differences of these genes between the two groups were further analyzed by T test. The datasets of GSE125989 and GSE43837 were used for validation.

### Function and pathway enrichment analyses

These immune-related DEGs were subjected to Gene Ontology (GO) [21] and KEGG [22] pathway using ClusterProfiler [23] (version 3.12.0). The GO analysis results included biological process (BP), cellular component (CC) and molecular function (MF). The significance threshold was p value < 0.05, and the enrichment number (count) was at least 2. The compareCluster function of the clusterProfiler package was applied to visualize the top 10 GO BP and KEGG enrichment results.

### Transcription factor (TF)-miRNA-mRNA co-regulatory network analysis

The miRNAs in the 3’UTR region of immune-related DEGs were predicted using relevant databases (miRWalk3.0 [24], TargetScan [25], miRDB [26], mirTarBase [27]), with a threshold score of >0.95. Combining the results from each database, miRNAs that were validated (MirTarBase) and predicted in at least one other database were selected as the final mRNA-miRNA relationship pairs. HMDD V3.2 database [28] was used to retrieve the keyword “breast neoplasms” (synonyms of breast cancer) to further validate the predicted miRNAs. Then based on the online database TRRUST [29], the TF-mRNA pairs associated with immune-related DEGs and possible action mode (activation, suppression or unknown) were predicted. The mRNA-miRNA relationship pairs and TF-mRNA relationship pairs were integrated to construct the network using Cytoscape [30]. Additionally, GO and KEGG analyses were performed for the TF and immune-related DEGs in the network.

### Breast cancer associated pathway screening and gene annotation

According to the breast neoplasms related pathways included in Comparative Toxicogenomics Database
null
DEGs, and 42 immune-related genes were screened. T-test revealed that 27 genes, such as *THY1*, present significant differences in expression levels between two groups. These genes were significantly enriched in BP term associated with positive regulation of GTPase activity (*ALDH1A1*, *APC2*, *DOCK2* and *THY1*). Additionally, other glycan degradation pathway was significantly enriched (Fig. 5).

**TF-miRNA-mRNA network analysis**
A total of 9 miRNA-mRNA pairs were predicted, which included 5 mRNAs and 9 miRNAs, such as miR-520a and miR-361-3p. In addition, 12 TF-mRNA pairs were obtained, involving 8 mRNAs and 11 TFs. Based on the miRNA-mRNA and TF-mRNA intracation pairs, a TF-miRNA-mRNA regulatory network was constructed (Fig. 6a). Function analysis showed that the TFs and mRNAs in the network were significantly enriched in lipid homeostasis, and cholesterol homeostasis associated BP terms (Fig. 6b). Moreover, they were involved in 8 pathways, such as transcriptional misregulation in cancer, PPAR signaling pathway, AMPK signaling pathway, and breast cancer (Fig. 6c).

**PPI network analysis**
Based on the immune-related genes, 46 PPI pairs were obtained and the constructed PPI network included 31 nodes (21 up-regulated and 10 down-regulated ones) (Fig. 7). Among the 31 nodes, *NEUROD1*, *THY1*, *ALDH1A1*, *GBX2*, *MIXL1*, *CDH8* and *ASPN* had degrees more than 5, and were considered as hub nodes.

**Drug-gene interaction analysis**
A total of 10 drug-gene interaction pairs were identified based on the immune-related genes, which involved 10 drugs (busulfan, retinol, tretinoin, zanamivir, deferoxamine, temazepam, diazepam, oxazepam, bromazepam and nitrazepam) and 5 mRNAs (*PRSS1*, *ALDH1A1*, *NEU2*, *NEUROD1*, *THY1*).
In detail, GABRQ interacted with temazepam, diazepam, oxazepam, bromazepam and nitrazepam; ALDH1A1 interacted with tretinoin and retinol; NEU2 interacted with zanamivir; PRSS1 interacted with busulfan (Fig. 8).

Metastatic recurrence survival analysis of key genes

The Venn diagram of the intersection of DEGs in the three datasets and immune-related genes is shown in Fig. 9a. The genes verified by GSE43817 dataset were DOCK2, HCN4, HASPIN, STK33 and KYNU. The gene verified by GSE125989 dataset was THY1. The genes verified by the two datasets were ASPN and CD1B. These genes were considered as key genes and were performed metastatic recurrence survival analysis. Based on the analysis of the bc-GenExMiner v4.4 database, CD1B, THY1 and DOCK2 were found to affect the metastatic recurrence of triple-negative breast cancer. As shown in Fig. 9b, high expression of THY1 was more likely to cause metastasis of breast cancer, while low expression of CD1B and DOCK2 was likely to cause metastasis of breast cancer.

Literature retrieval of key genes

Among the key genes, ASPN, DOCK2, THY1 and KYNU were found to be associated with breast cancer based on NCBI Entrez database. Based on the GenCLiP 2.0 database, only THY1 was associated with breast cancer.

Discussion

Brain metastases commonly originate from breast, lung, and melanoma. However, brain metastases are hard to treat because most drugs cannot penetrate the blood brain barrier and often affect multiple areas of the brain [40]. Therefore, identification of new biomarkers may contribute to the development of individualized
treatment. The present study is the first time to explore the immune-related genes in breast cancer with brain metastases. The present results showed that the tumor immune microenvironment in brain metastases was immunosuppressed compared with primary cancer. Compared with primary cancer samples, the infiltration ratio of plasma cells in brain metastases samples was significantly higher, while the infiltration ratio of macrophages M2 cells in brain metastases samples was significantly lower. Total 42 immune-related genes were identified, such as THY1 (Thy-1 cell surface antigen) and NEU2 (neuraminidase 2). THY1 was a hub protein in the PPI network. NEU2 interacted with zanamivir. CD1B (CD1b molecule), THY1 and DOCK2 (dedicator...
of cytokinesis) were found to be implicated in the metastatic recurrence of breast cancer.

The brain has long been regarded as an immune privileged organ, whereas, this view was revised since a lymphatic vessel network of brain tissues was found in the dura mater in mice [41, 42]. Our study suggested an immune suppressive environment in the brain metastases, partly exemplified by significantly decreased stromal score, immune score, and ESTIMATE score in brain metastases samples compared with that in primary cancer group. Our results were in accordance with a recent study of Kudo et al. [43], who coupled immune gene expression profiling and topological gene–gene network analysis and demonstrated an immune suppressive microenvironment in the brain metastases of non-small-cell lung cancer.

Tumor microenvironment is composed of various nonmalignant stromal cells, among which tumor-associated macrophages are the most prominent type of migratory hematopoietic cells [44]. In breast, the tumor-associated macrophages are primarily pro-tumorogenic M2-like macrophages, which promote the progression and metastasis of breast cancer by releasing various cytokines [45]. Plasma cells can affect antitumor immunity by regulating T-cell responses, or excluding immune-suppressive cell types to provide a permissive tumor microenvironment for CD8+ tumor-infiltrating lymphocytes, the key mediators of antitumor immunity [46]. Our results may devise new strategies for immunotherapy of breast cancer with brain metastases—by targeting macrophages or plasma cells.

In this study, 42 immune-related genes were identified, such as THY1, NEU2, CD1B and DOCK2. THY1 was one of hub proteins in the PPI network. In PPI network, the topological placement of a protein is connected with its biological essentiality. The densely connected hub proteins are more likely to be essential proteins, which is referred to as the “centrality-lethality rule” [47]. THY1 is a glycosylphosphatidylinositol-anchored protein, which has been proposed to play important roles in cancers [48]. Function analysis showed that THY1 was significantly enriched in function associated with positive regulation of GTPase activity. GTPases can be activated when binding to GTP. Once activated, GTPases carry out many functions in cells, such as the regulation of cell proliferation, apoptosis, and differentiation [49]. It has been reported that in the case of tumor progression, mutations in Ras related small GTPases can increase the proliferation, survival, and adhesion of tumor cells, tending toward a metastatic phenotype [50]. Additionally, high expression of THY1 was more likely to cause metastasis of breast cancer. Taken together, we speculated that THY1 may play a role in brain metastases of breast cancer via positive regulation of GTPase activity. Additionally, it may serve as a prognostic indicator to predict the metastasis of breast cancer.

NEU2 was involved in the pathway of other glycan degradation. In mammalian tissues, glycans exist in free forms or conjugated forms, which participate in various
Fig. 6  a The constructed transcription factor (TF)-miRNA-mRNA regulatory network. The red round nodes represent upregulated differentially expressed genes (DEGs); the blue round nodes represent downregulated DEGs; the green triangle nodes represent miRNAs; green rhombus nodes represent TF. The gray lines represent the interaction relationship; the red lines represent the activation relationship of TF-mRNA; the blue lines represent the inhibition relationship of TF-mRNA. B and C: The GO function (b) and KEGG pathway (c) enriched by the TF-mRNA
biological processes, such as host–pathogen interactions, cell migration and metastasis, and initiation of immune response [51]. Study has reported that glycan changes in malignant cells take many forms and mediate key pathophysiological events during various stages of tumor progression [52]. In the tumor environment, glycosylation changes allow tumor cells to usurp many development events, allowing tumor cells to invade and spread throughout the organism. Thus, we speculated that the upregulation of NEU2 may be involved in brain metastases of breast cancer through pathway of other glycan degradation. Drug-gene interaction analysis showed that NEU2 interacted with zanamivir. Zanamivir is an inhibitor of the enzyme neuraminidase, a surface glycoprotein necessary for the replication of type A and B influenza viruses [53]. Its role in cancer is rarely reported. Now we speculated that zanamivir may serve as an antineoplastic drug in breast cancer with brain metastases by targeting NEU2.

CD1B belongs to the group 1 CD1 family of transmembrane glycoproteins, and is associated with major histocompatibility complex class I-like molecules. CD1 molecules regulate the expression of some self- and foreign-lipid antigens to T-cell receptors on T cells [54]. A recent study has indicated that there are different expression patterns of CD1 molecules between tumor cells and normal cells [55]. More recently, low expression of CD1B was reported to be correlated with poorer biochemical recurrence-free survival in prostate cancer. Similar result was found in our study, that was, low expression of CD1B was likely to cause metastatic recurrence of breast cancer.

DOCK2 is a member of the CDM protein family, which can regulate cell motility and cytokine production by activating Rac in mammalian hematopoietic cells. Additionally, DOCK2 plays a critical role in the modulation of the immune system [56]. Hu et al. [57] have reported that low expression of DOCK2 is associated with poorer prognosis of acute myeloid leukemia. Recent study reported that DOCK2 hypermethylation was associated with biochemical recurrence after radical prostatectomy in prostate cancer [58]. To our knowledge, there was no study about the role of DOCK2 in breast cancer. Together with our results, we
speculated that DOCK2 may be a prognostic marker of metastatic recurrence in breast cancer. Despite these findings, there existed a limitation in this study. Due to lack of adequate clinical samples, there was no experimental evidence to support our analysis results. Thus, further experimental studies are needed to confirm our results.

Conclusions
Our study indicated that tumor immune microenvironment in brain metastases of breast cancer was immunosuppressed compared with primary cancer. Targeting macrophages or plasma cells may be new strategies for immunotherapy of breast cancer with brain metastases. THY1 and NEU2 may be potential therapeutic targets for breast cancer with brain metastases, and THY1, CD1B and DOCK2 may serve as potential prognostic markers for improvement of brain metastases survival.
